Reading the content from the same address as it was written to provides the following sequence of bytes, identical to the write case:

- 01...02...03...04...05...06...07...08

This results in the AHB Buffer filled with:

**Table 10-30. Resulting AHB Buffer Content**

AHB Buffer Entry	Content
0	64'h01_02_03_04_05_06_07_08

#### 10.2.7.3.1 Readout of the AHB Buffer via Memory Mapped Read

The AHB Buffer content appears at read access on the AMBA AHB interface at the QuadSPI module boundary:

- (1a): 32 Bit Read Access: <- 0x01\_02\_03\_04
- (2a): 32 Bit Read Access: <- 0x05\_06\_07\_08
- (1/2): 64 Bit Read Access: <- 0x01\_02\_03\_04\_05\_06\_07\_08

## 10.2.8 Serial Flash Devices

Several different vendors make flash devices with a QuadSPI interface. At present there is no set standard for the QuadSPI instruction set. Most common commands currently have the same instruction code for all vendors, however some commands are unique to specific vendors. Some example sequences are provided below.

### 10.2.8.1 Example Sequences

This section provides the example sequences of the QuadSPI module.

**Table 10-31. Exit 4 x I/O Read Enhance Performance Mode (XIP) (Macronix) and Read Status**

INSTR	PAD	OPERAND	COMMENT
CMD	0x0	0xEB	4xIO Read Command
ADDR	0x2	0x18	24 Bit address to be send on 4 pads
MODE	0x2	0x00	2 mode cycles (exit XIP)
DUMMY	0x0	0x04	4 dummy cycles
READ	0x2	0x08	Read 64 bits
CMD	0x0	0x05	Read Status register
READ	0x0	0x01	Status register data
STOP	0x0	0x00	STOP, Instruction over

#### 10.2.8.1.1 Fast Read Sequence (Macronix/Numonyx/Spansion/Winbond)

The following table shows the fast read sequence for Macronix/Numonyx/Spansion/Winbond flashes.

**Table 10-32. Fast Read sequence**

Instruction	Pad	Operand	Comment
CMD	0x0	0x0B	Fast Read command = 0x0B
ADDR	0x0	0x18	24 Addr bits to be sent on one pad
DUMMY	0x0	0x08	8 Dummy cycles
READ	0x0	0x04	Read 32 Bits on one pad
JMP_ON_CS	0x0	0x00	Jump to instruction 0 (CMD)

### 10.2.8.1.2 Fast Dual I/O DT Read Sequence (Macronix)

The following table shows the Fast Dual I/O DT read sequence for Macronix flashes.

**Table 10-33. Fast Dual I/O DT Read sequence**

Instruction	Pad	Operand	Comment
CMD	0x0	0xBD	Fast Dual I/O DT read command = 0xBD
ADDR_DDR	0x1	0x18	24 Addr bits to be sent on 2 pads in DDR mode
MODE4_DDR	0x1	0x00	P2=P0 or P3=P1 is necessary. Refer to Macronix datasheet for details. One clock cycle for mode.
DUMMY	0x0	0x06	6 Dummy cycles
READ_DDR	0x1	0x04	Read 32 Bits on 2 pads in DDR mode
JMP_ON_CS	0x0	0x00	Jump to instruction 0 (CMD)

### 10.2.8.1.3 Fast Read Quad Output (Winbond)

The following table shows the Fast read quad output sequence for Winbond memories

**Table 10-34. Fast Read Quad output sequence**

Instruction	Pad	Operand	Comment
CMD	0x0	0x6B	Fast read quad output command = 0x6B
ADDR	0x0	0x18	24 Addr bits to be sent on 1 pad
DUMMY	0x0	0x08	8 Dummy cycles
READ	0x2	0x04	Read 32 Bits on 4 pads
JMP_ON_CS	0x0	0x00	Jump to instruction 0 (CMD)

### 10.2.8.1.4 4 x I/O Read Enhance Performance Mode (XIP) (Macronix)

The following table shows the 4 x I/O Read Enhance Performance Mode for Macronix flashes. The enhanced performance mode is also known as XIP mode.

**Table 10-35. Fast Read Quad output sequence**

Instruction	Pad	Operand	Comment
CMD	0x0	0xEB	4xI/O Read command = 0xEB
ADDR	0x2	0x18	24 Addr bits to be sent on 4 pads
MODE	0x2	0xA5	2 mode cycles
DUMMY	0x0	0x04	4 Dummy cycles
READ	0x2	0x04	Read 32 Bits on 4 pads
JMP_ON_CS	0x0	0x01	Jump to instruction 1 (ADDR)

When in XIP mode the software should ensure that all the flashes connected to the controller are in XIP mode. As a part of initializing the controller, all the flashes may be enabled with XIP by carrying out dummy reads.

### 10.2.8.1.5 Dual Command Page Program (Numonyx)

The following table shows the Dual command page program sequence for Numonyx flashes.

**Table 10-36. Dual Command Page Program sequence**

Instruction	Pad	Operand	Comment
CMD	0x1	0x02	Dual command page program = 0x02 on 2 pads
ADDR	0x1	0x18	24 Addr bits to be sent on 2 pads
WRITE	0x1	0x20	Write 32 Bytes on 2 pads
STOP	0x0	0x00	STOP, Instruction over

### 10.2.8.1.6 Sector Erase (Macronix/Spansion/Numonyx)

The following table shows the Sector erase sequence for Macronix/Spansion/Numonyx flashes

**Table 10-37. Sector Erase sequence**

Instruction	Pad	Operand	Comment
CMD	0x0	0xD8	Sector erase command = 0xD8
ADDR	0x0	0x18	24 Addr bits to be sent on 1 pad
STOP	0x0	0x00	STOP, Instruction over

### 10.2.8.1.7 Read Status Register (Macronix/Spansion/Numonyx/Winbond)

The following table shows the Read status register sequence for Macronix/Spansion/Numonyx/Winbond flashes.

**Table 10-38. Read Status Register Sequence**

Instruction	Pad	Operand	Comment
CMD	0x0	0x05	Read status register command = 0x05
READ	0x0	0x01	Read status register data
STOP	0x0	0x00	STOP, Instruction over

### 10.2.8.2 Dual Die Flashes

Certain serial flash vendors provide dual-die packages which are essentially two devices (dies) stacked within the same package to increase the memory capacity of a single package. These two devices within a package share the same data and clock pins, but have individual Chip Selects. QuadSPI controller provides support for two dual-die packages to be connected simultaneously. The figure below shows the two dual-die packages and the naming conventions used in this document. For simplicity, the data pins are shown to be unidirectional.

Figure 10-23. Dual-die support

Since the two devices within one package share the same i/o pads, they cannot function in parallel mode. Software should ensure that when QuadSPI is configured in parallel mode the two selected flash devices are from different dual-die packages.

### 10.2.8.3 Boot initialization sequence

The following are the recommended sequence of steps for booting from QuadSPI:

- System out of reset and flash available (300us)
- Clocks still at very low frequency. Clock tree configured, I/O pins configured. First request sent to QuadSPI for address 0x0 of flash.

- The reset command sequence in QuadSPI has 0x03 (basic read command) which is applicable to all flashes at < 50MHz serial flash clock
- The first few bytes of data is read from the flash which contains the following information:
  - The total sizes of all the flashes connected on board
  - Whether DDR mode supported
  - Frequency of DDR operation
  - Continuous mode entry sequence
  - 24bit or 32bit addressing (assuming 24bit for first accesses)
- All the serial flashes are configured
  - Quad Mode enabled
  - Dummy reads to enter into XIP
- QuadSPI is configured
  - Parallel enable set
  - LUT configured for highest performance reads
  - DDR mode enabled (if applicable)
  - Buffers configured
- Serial flash clock frequency increased.
- Boot reads happen in parallel, DDR enabled, quad output mode @66MHz.

## 10.2.9 Sampling of Serial Flash Input Data

### 10.2.9.1 Internal Sampling of Serial Flash Input Data

Depending from the actual implementation there is a delay between the internal clocking in the QuadSPI module and the external serial flash device. Refer to the following figure for an overview of this scheme.

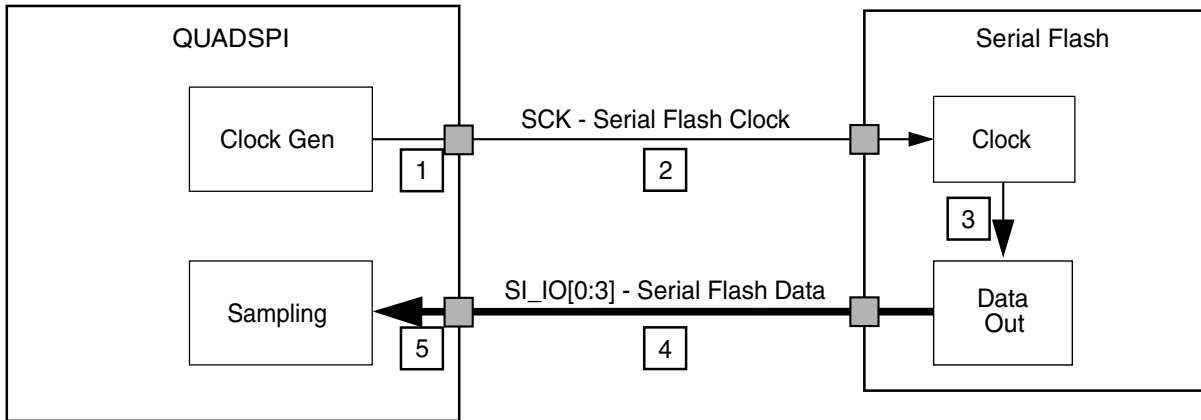

Figure 10-24. Serial Flash Sampling Clock Overview

**Note**

The arrival of the serial flash data in the sampling stage of the QuadSPI module are given in the following figure. Note that the amount of the total delay  $t_{Del,total}$  is very specific to the characteristics of the actual implementation.

Note also that the serial flash device clock SCK is inverted with respect to the QuadSPI internal reference clock.

Figure 10-25. Serial Flash Sampling Clock Timing

The rising edge of the internal reference clock is taken as timing reference for the data output of the serial flash. After a time of  $t_{Del,total}$  the data arrive at the internal sampling stage of the QuadSPI module.

According to the Serial Flash Sampling Clock Overview figure, the following parts of the delay chain contribute to  $t_{Del,total}$ :

1. Output delay of the serial flash clock output of the device containing the QuadSPI module
2. Wire delay of application/PCB from the device containing the QuadSPI module to the external serial flash device
3. Clock to data out delay of the external serial flash device, including input and output delays
4. Wire delay of application/PCB from the external serial flash device to the device containing the QuadSPI module
5. Input delay belonging to the data in input

The possible points in time for the sampling of the incoming data are denoted as N/1, I/1, N/2 and I/2 above. The sampling point relevant for the internal sampling is configured in the QSPI\_SMPR register, refer to [Sampling Register \(QuadSPI\\_SMPR\)](#) for details. Note that the falling edges of the reference clock are not actually used, instead the inverted clock is used for sampling at these positions. The following table gives an overview of the available configurations for the commands running at regular (full) speed:

**Table 10-39. Sampling Configuration**

Sampling Point	Description	Delay [FSDLY] [HSDLY]	Phase [FSPHS] [HSPHS]	QSPI_SMPR for Full Speed Setting <sup>1</sup>
N/1	sampling with non-inverted clock, 1 sample delay	0	0	0x0000000x
I/1	sampling with inverted clock, 1 sample delay	0	1	0x0000002x
N/2	sampling with non-inverted clock, 2 samples delay	1	0	0x0000004x
I/2	sampling with inverted clock, 2 samples delay	1	1	0x0000006x

1. 'x' is not considered here

Depending from the actual delay and the serial flash clock frequency the appropriate sampling point can be chosen. The following remarks should be considered when selecting the appropriate setting:

- Theoretically there should be 2 settings possible to capture the correct data since the serial flash output is valid for 1 clock cycle, disregarding rise and fall times and timing uncertainties.
- Depending from the timing uncertainties it may turn out in actual applications that only one possible sample positions remains. This is subject to careful consideration depending from the actual implementation.

- The delay  $t_{Del,total}$  is an absolute size to shift the point in time when the serial flash data get valid at the QuadSPI input.
- For decreasing frequency of the serial flash clock the distance between the edges increases. So for large differences in the frequency the required setting may change.
- For commands running at half of the regular serial flash clock (QSPI\_SMPR[HSENA] bit set) the sampling point must be figured separately to allow for the compensation of the absolute shift in time with respect to the sample-relative setting in the QSPI\_SMPR register.

### 10.2.9.2 DDR Mode

The increasing requirement of improved throughput has introduced the double data rate (DDR) mode. In DDR mode, the data is transferred on both the rising and falling edges of the serial flash clock. The DDR serial flashes sample as well as drive the data on both rising and falling edges of serial flash clock.

### 10.2.10 Serial Flash Data Input Timing

There are sampling modes for input flash data:

- Internal sampling - Input serial flash data is captured by internal serial clock. In SDR mode, serial data is sampled by serial clock 1x (ser\_clk\_1x) rise edge. In DDR mode, serial data is sampled by serial clock 4x (ser\_clk\_4x) rise edge.
- Loopback DQS sampling - Soc will output serial data strobe with internal serial clock. This serial data strobe would be loopback from pad and used to sample input serial data. In SDR mode, serial data is sampled by loopback DQS rise edge. In DDR mode, serial data is sampled by loopback DQS both edge

**NOTE**

DQS pad need to be set to force input for loopback.

- Flash DQS sampling - Some serial Flash device provide the data strobe output together with serial data. This strobe signal is used to sample input serial data directly. In SDR mode, serial data is sampled by Flash DQS rise edge. In DDR mode, serial data is sampled by Flash DQS both edge

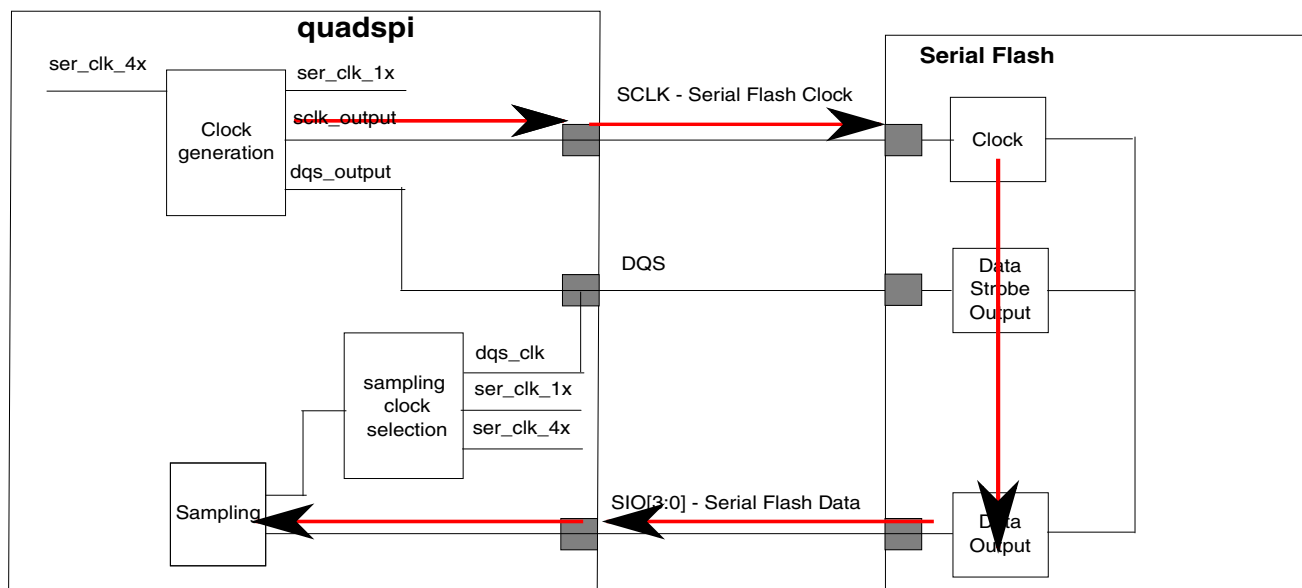

Following table shows selection for sampling mode:

Sampling mode	DQS_EN	DQS_LOOPBACK_EN
Internal sampling	0	doesn't matter

*Table continues on the next page...*

Sampling mode	DQS_EN	DQS_LOOPBACK_EN
Loopback DQS sampling	1	1
Flash DQS sampling	1	0

Serial flash data and clock path for input timing is shown in the following figure.

**Figure 10-26. Serial flash data and clock path**

### NOTE

The red line is for data input path, the blue line is for DQS loopback path, and the purple line is for DQS input path from Serial Flash.

Total delay ( $T_{total\_delay\_data}$ ) for serial flash data input is the sum of following delay:

1. Output delay of serial flash clock from internal serial clock to SCLK pad inside SOC
2. Wire delay of serial flash clock (SCLK) from SOC to external Serial Flash Device
3. Clock to Output Valid time of external Serial Flash Device
4. Wire delay of serial flash data (SIO) from external serial Flash Device to SOC
5. Input delay of serial flash data from SIO pad to internal sample register

Total delay ( $T_{total\_delay\_loopback\_dqs}$ ) for loopback DQS clock is the sum of following delay:

1. Output delay of DQS clock from internal serial clock to DQS pad inside SOC
2. Input delay of DQS clock from DQS pad to internal sample register

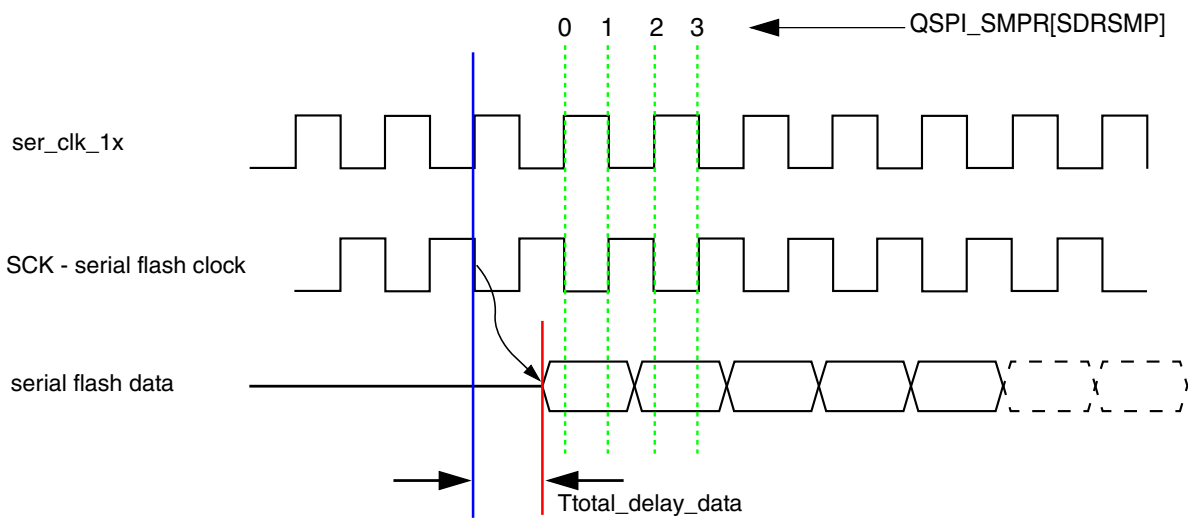

Total delay ( $T_{total\_delay\_flash\_dqs}$ ) for Flash DQS clock is the sum of following delay:

1. Output delay of serial flash clock from internal serial clock to SCLK pad inside SOC
2. Wire delay of serial flash clock (SCLK) from SOC to external Serial Flash Device

3. Clock to DQS Output time of external Serial Flash Device
4. Wire delay of serial flash data strobe (DQS) from external serial Flash Device to SOC
5. Input delay of DQS clock from DQS pad to internal sample register

### 10.2.10.1 Input timing in SDR mode with internal sampling

Input Timing diagram in SDR mode with internal sampling is show in the figure below.

**Figure 10-27. Internal sample SDR**

There are four sample points for this sampling mode, which is determined by register field QSPI\_SMPR.SDRSMP.

Sampling point need to be select correctly to meet both Setup and Hold timing for internal sample registers:

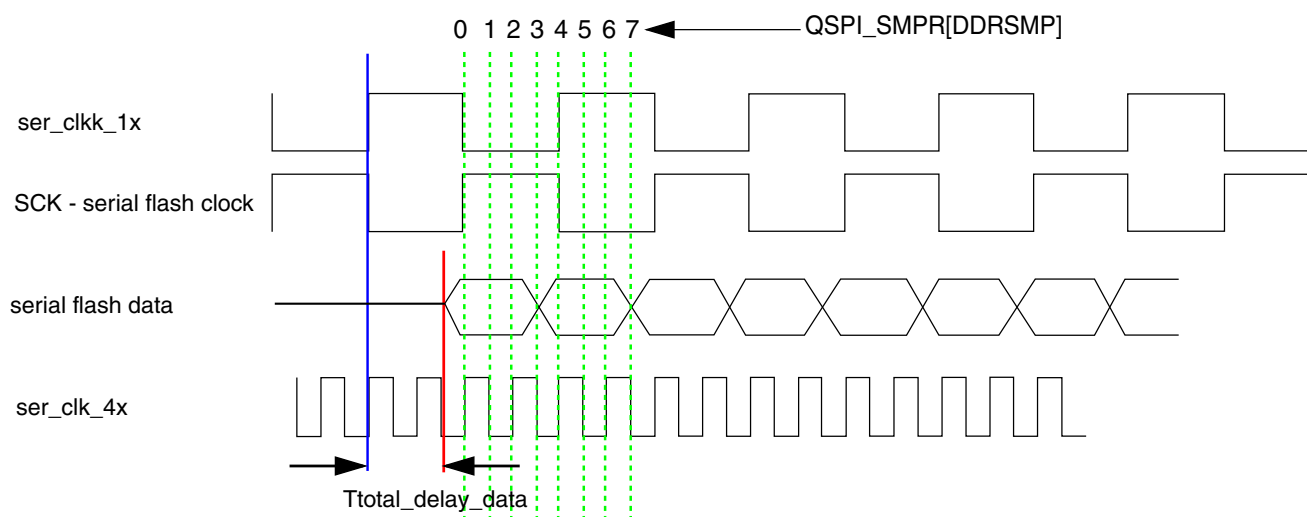

- For sample point N, Setup requirement is:  $T_{cycle} * (N+2) / 2 > T_{total\_delay\_data,max}$
- For sample point N, Hold requirement is:  $T_{total\_delay\_data,min} > T_{cycle} * N / 2$

#### NOTE

$T_{cycle}$  is the cycle of ser\_clk\_1x.  $T_{total\_delay\_data,max}$  is maximum delay of serial data input path.  $T_{total\_delay\_data,min}$  is the minimum delay of serial data input path.  $N=0,1,2,3$

### 10.2.10.2 Input timing in DDR mode with internal sampling

Input Timing diagram in SDR mode with internal sampling is show in the following figure.

There are 8 sample points for this sampling mode, which is determined by register field `DDRSMP`.

Sampling point need to be select correctly to meet both Setup and Hold timing for internal sample registers:

- For sample point N, Setup requirement is:  $T_{\text{cycle}} * (N+2)/8 > T_{\text{total\_delay\_data,max}}$
- For sample point N, Hold requirement is:  $T_{\text{total\_delay\_data,min}} > T_{\text{cycle}} * N/8$

### 10.2.10.3 Input timing in SDR mode with loopback DQS sampling

Input Timing diagram in SDR mode with internal sampling is show in the following figure.

**Figure 10-28. Input timing in SDR mode with loopback DQS sampling**

In SDR mode and loopback sampling mode, DQS\_PHASE\_EN should be set 1.

For this sample point, the Setup requirement is:  $T_{\text{cycle}} > \max(T_{\text{total\_delay\_data}} - T_{\text{total\_delay\_loopback\_dqs}})$ . The Hold requirement is:  $\min(T_{\text{total\_delay\_data}} - T_{\text{total\_delay\_loopback\_dqs}}) > 0$ .

#### 10.2.10.4 Input timing in DDR mode with loopback DQS sampling

Input Timing diagram in DDR mode with internal sampling is show in the following figure.

**Figure 10-29. Input timing in DDR mode with loopback DQS sampling**

In DDR mode and loopback sampling mode, `DQS_PHASE_EN` should be set 0.

For this sample point, the Setup requirement is:  $T_{cycle} > \max(T_{total\_delay\_data} - T_{total\_delay\_loopback\_dqs})$ . The Hold requirement is:  $\min(T_{total\_delay\_data} - T_{total\_delay\_loopback\_dqs}) > 0$ .

### 10.2.10.5 Input timing in SDR mode with flash DQS sampling

Input Timing diagram in SDR mode with internal sampling is show in the following figure.

**Figure 10-30. Input timing in SDR mode with flash DQS sampling**

In this sampling mode, there will be a setup/hold requirement on Flash serial Data and Flash serial Data Strobe. This value will be specified in the data sheet.

### 10.2.10.6 Input timing in DDR mode with flash DQS sampling

Input Timing diagram in DDR mode with internal sampling is show in the following figure.

**Figure 10-31. Input timing in DDR mode with flash DQS sampling**

In this sampling mode, there will be a setup/hold requirement on Flash serial Data and Flash serial Data Strobe. This value will be specified in the data sheet.

### 10.2.10.7 Data Strobe Signal functionality

Some external serial flashes provide the data strobe (DQS/RDS) output which is fed directly to the QuadSPI module. The strobe (DQS/RDS) signal needs to be delayed to have the edges aligned to the data valid period. QuadSPI internally samples the incoming data at posedge of the strobe signal for SDR and on both the edges of the strobe signal for DDR. Refer to the figure for more detail.

Figure 10-32. Data strobe signal functionality

### 10.2.11 Output timing in SDR mode

Output timing diagram in SDR mode is show in the following figure.

**Figure 10-33. Output timing in SDR mode**

In SDR mode, quadspi output serial data with internal serial clock rise edge 1x (`ser_clk_1x`). Flash Device has requirement on Data and Clock setup and hold timing.

### 10.2.12 Output timing in DDR mode

Output Timing diagram in DDR mode is show in the following figure.

**Figure 10-34. Output timing in DDR mode**

In DDR mode, quadspi output serial data with internal serial clock both edge 1x (`ser_clk_1x`) and then delay one `ser_clk_4x` cycle for hold timing.

**NOTE**

TX\_DDR\_DELAY\_EN should be set to 1 for DDR mode.

**10.2.13 AHB RX Data Buffer (QSPI\_ARDB0 to QSPI\_ARDB31)****10.2.13.1 AHB RX Data Buffer (QSPI\_ARDB0 to QSPI\_ARDB31)****NOTE**

See the System Memory map in this document for the base address of the QSPI AHB RX Data Buffer.

**memory map**

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

### 10.2.13.1.1 AHB RX Data Buffer register (ARDBn)

The AHB RX Data Buffer register 0 to 31 can be used to read the buffer content of the RX Buffer from successive addresses. QSPI\_ARDB0 corresponds to the RX Buffer register entry corresponding to the current value of the read pointer with increasing order.

The increment of the read pointer depends from the access scheme (DMA or flag-driven). Refer to "Data Transfer from the QuadSPI Module Internal Buffers" section in [Flash Read](#) section, RX Buffer, data read via register interface and AHB read, for the description of successive accesses to the RX Buffer content. Refer also to [Byte Ordering of Serial Flash Read Data](#) for the byte ordering scheme.

Valid address range accessible in the QSPI\_ARDB $n$  range depends from the number of RX Buffer entries implemented and from the number of valid buffer entries available in the RX Buffer.

- Example 1, RX Buffer filled completely with 32 words: In this case the address range for valid read access extends from QSPI\_ARDB0 to QSPI\_ARDB31.
- Example 2, RX Buffer filled with 5 valid words, RX Buffer fill level QSPI\_RBSR[RDBFL] is 5. In this case an access to QSPI\_ARDB4 provides the last valid entry.

Address: 0h base + 0h offset + (4d × i), where i=0d to 31d

### ARDB $n$ field descriptions

Field	Description
ARXD	ARDB provided RX Buffer Data. Byte order (endianness) is identical to the RX Buffer Data Registers.

## 10.2.14 Peripheral Bus Register Descriptions

This section provides the peripheral bus register information of the QuadSPI module.

This section provides the memory map and register definitions of the QuadSPI module.

### QuadSPI memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page

## QuadSPIx\_MCR field descriptions

Field	Description
31–27 Reserved	This field is reserved.

*Table continues on the next page...*

**QuadSPIx\_MCR field descriptions (continued)**

Field	Description
26 DQS_PHASE_EN	This bit controls internal DQS output phase. If DQS_EN and DQS_LOOPBACK_EN are both set to 1, this bit should be set in SDR mode, and cleared in DDR mode. If either DQS_EN or DQS_LOOPBACK_EN is set to 0, this bit is ignored.
25 DQS_LOOPBACK_EN	Quadspi will output serial data strobe signal which will be loopback from pad to sample input flash serial data. Please note pad should be force input for loopback. Quadspi will output serial data strobe signal which will be loopback from pad to sample input flash serial data. Please note pad should be force input for loopback. This bit is a don't care when DQS_EN is set to 0. 1'b1 DQS loopback sampling enabled 1'b0 DQS loopback sampling disabled
24 DQS_LOOPBACK_FROM_PAD	This bit should always be set to '1' when DQS_LOOPBACK_EN is set to '1'. When DQS_LOOPBACK_EN is set to '1', this bit is ignored.
23–20 Reserved	This field is reserved.
19–16 Reserved	This field is reserved. This field is reserved and should always be set to 0xF.
15 Reserved	This field is reserved. This field is reserved.
14 MDIS	Module Disable. The MDIS bit allows the clock to the non-memory mapped logic in the QuadSPI to be stopped, putting the QuadSPI in a software controlled power-saving state. Please refer to , for more information. 0 Enable QuadSPI clocks. 1 Allow external logic to disable QuadSPI clocks.
13–12 Reserved	This field is reserved.
11 CLR_TXF	Clear TX FIFO/Buffer. Invalidate the TX Buffer content. 0 No action. 1 Read and write pointers of the TX Buffer are reset to 0. QSPI_TBSR[TRCTR] is reset to 0.
10 CLR_RXF	Clear RX FIFO. Invalidate the RX Buffer. 0 No action. 1 Read and write pointers of the RX Buffer are reset to 0. QSPI_RBSR[RDBFL] is reset to 0.
9–8 Reserved	This field is reserved.
7 DDR_EN	DDR mode enable: 0 2x and 4x clocks are disabled for SDR instructions only 1 2x and 4x clocks are enabled supports both SDR and DDR instruction.
6 DQS_EN	DQS enable: This field is valid for both SDR and DDR mode. For more details Refer <a href="#">Data Strobe Signal Functionality</a>

Table continues on the next page...

## QuadSPIx\_MCR field descriptions (continued)

Field	Description
	0 DQS disabled. 1 DQS enabled- When enabled, the incoming data is sampled on both the edges of DQS input when QSPI_MCR[DDR_EN] is set, else, on only one edge when QSPI_MCR[DDR_EN] is 0. The QSPI_SMPR[DDR_SMP] values are ignored.
5-4 Reserved	This field is reserved.
3-2 END_CFG	Defines the endianness of the QSPI module. For more details refer to <a href="#">Byte Ordering Endianness</a>
1 SWRSTHD	Software reset for AHB domain  <b>NOTE:</b> Please keep other fields value when write to SWRSTHD and SWRSTSD  <b>NOTE:</b> These software reset don't reset register setting but only reset internal flip-flops in quadspi controller  <b>NOTE:</b> To remove the reset, need to write 0 to SWRSTHD and SWRSTSD  0 No action 1 AHB domain flops are reset. Does not reset configuration registers.  It is advisable to reset both the serial flash domain and AHB domain at the same time. Resetting only one domain might lead to side effects.
0 SWRSTSD	Software reset for Serial Flash domain  <b>NOTE:</b> Please keep other fields value when write to SWRSTHD and SWRSTSD  <b>NOTE:</b> These software reset don't reset register setting but only reset internal flip-flops in quadspi controller  <b>NOTE:</b> To remove the reset, need to write 0 to SWRSTHD and SWRSTSD  0 No action 1 Serial Flash domain flops are reset. Does not reset configuration registers.  It is advisable to reset both the serial flash domain and AHB domain at the same time. Resetting only one domain might lead to side effects.

### 10.2.14.2 IP Configuration Register (QuadSPIx\_IPCR)

The IP configuration register provides all the configuration required for an IP initiated command. An IP command can be triggered by writing in the SEQID field of this register. If the SEQID field is written successfully, a new command to the external serial flash is started as per the sequence pointed to by the SEQID field. Refer to [Normal Mode](#), for details about the command triggering and command execution.

*Write:*

- $QSPI\_SR[IP\_ACC]=0$

## AHB RX Data Buffer (QSPI\_ARDB0 to QSPI\_ARDB31)

Address: Base address + 8h offset

### QuadSPIx\_IPCR field descriptions

Field	Description
31–28 Reserved	This field is reserved.
27–24 SEQID	Points to a sequence in the Look-up-table. The SEQID defines the bits [6:2] of the LUT index. The bits [1:0] are always assumed to be 0. Refer to <a href="#">Look-up Table</a> for more details. A write to this bit -field triggers a transaction on the serial flash interface.
23–17 Reserved	This field is reserved.
16 PAR_EN	When set, a transaction to two serial flash devices is triggered in parallel mode. Refer to <a href="#">Parallel Flash Mode</a> for more details.
IDATSZ	IP data transfer size: Defines the data transfer size in bytes of the IP command.

## 10.2.14.3 Flash Configuration Register (QuadSPIx\_FLSHCR)

The Flash configuration register contains the flash device specific timings that must be met by the QuadSPI controller for the device to function correctly.

Write:

- $QSPI\_SR[AHB\_ACC] = 0$
- $QSPI\_SR[IP\_ACC] = 0$

Address: Base address + Ch offset

## QuadSPIx\_FLSHCR field descriptions

Field	Description
31–18 Reserved	This field is reserved.
17–16 TDH	Serial flash Data In hold time: This helps in meeting the Data In Hold time requirement of a Flash. This is valid only in DDR mode. Refer to <a href="#">Data input hold requirement of Flash</a> for details.  <b>NOTE:</b> This field should be set to 01 in DDR mode (DDR_EN=1) and set to 00 in SDR mode (DDR_EN=0). Other value are reserved.  00 Data aligned with the posedge of Internal reference clock of QuadSPI 01 Data aligned with 2x serial flash half clock 10 Reserved 11 Reserved
15–12 Reserved	This field is reserved.
11–8 TCSH	Serial flash CS hold time in terms of serial flash clock cycles.  <b>NOTE:</b> The actual delay between chip select assertion and clock fall edge is defined as: <ul style="list-style-type: none"> <li>• 1 SCK cycle if TCSH is set 0 or 1</li> <li>• N SCK cycle if TCSH is set N (N&gt;1)</li> </ul>
7–4 Reserved	This field is reserved. Reserved.
TCSS	Serial flash CS setup time in terms of serial flash clock cycles.  <b>NOTE:</b> <ol style="list-style-type: none"> <li>1. The actual delay between chip select assertion and clock fall edge is defined as: <ul style="list-style-type: none"> <li>• 0.5 SCK cycle if TCSS is set 0 or 1</li> <li>• N+0.5 SCK cycle if TCSS is set N (N&gt;1)</li> </ul> </li> <li>2. Any update to TCSS register bits is visible on the flash interface only from the second transaction following the update.</li> </ol>

## 10.2.14.4 Buffer0 Configuration Register (QuadSPIx\_BUF0CR)

This register provides the configuration for any access to buffer0. An access is routed to buffer0 when the master port number of the incoming AHB request matches the MSTRID field of the BUF0CR. Any buffer "miss" leads to a serial flash transaction being triggered as per the sequence pointed to the SEQID field. Buffer0 may also be configured as a high priority buffer by setting the HP\_EN field of this register.

*Write:*

- $QSPI\_SR[AHB\_ACC] = 0$

Address: Base address + 10h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R																
W	HP_EN	Reserved														
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

## AHB RX Data Buffer (QSPI\_ARDB0 to QSPI\_ARDB31)

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	ADATSZ								Reserved				MSTRID			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### QuadSPIx\_BUF0CR field descriptions

Field	Description
31 HP_EN	High Priority Enable: When set, the master associated with this buffer is assigned a priority higher than the rest of the masters. An access by a high priority master will suspend any ongoing prefetch by another AHB master and will be serviced on high priority. Refer to <a href="#">Flexible AHB Buffers</a> for details.
30–16 Reserved	This field is reserved.
15–8 ADATSZ	AHB data transfer size: Defines the data transfer size in 8 bytes of an AHB triggered access to serial flash. For example, a value of 0x2 will set transfer size to 16bytes. When ADATSZ = 0, the data size mentioned the sequence pointed to by the SEQID field overrides this value. SW should ensure that this transfer size is not greater than the size of this buffer.
7–4 Reserved	This field is reserved. Reserved.
MSTRID	Master ID: The ID of the AHB master associated with BUFFER0. Any AHB access with this master port number is routed to this buffer.

## 10.2.14.5 Buffer1 Configuration Register (QuadSPIx\_BUF1CR)

This register provides the configuration for any access to buffer1. An access is routed to buffer1 when the master port number of the incoming AHB request matches the MSTRID field of the BUF1CR. Any buffer "miss" leads to the buffer being flushed and a serial flash transaction being triggered as per the sequence pointed to by the SEQID field.

*Write:*

- $QSPI\_SR[AHB\_ACC] = 0$

Address: Base address + 14h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved																ADATSZ				Reserved		MSTRID									
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### QuadSPIx\_BUF1CR field descriptions

Field	Description
31–16 Reserved	This field is reserved.
15–8 ADATSZ	AHB data transfer size: Defines the data transfer size in 8 bytes of an AHB triggered access to serial flash. For example, a value of 0x2 will set transfer size to 16bytes. When ADATSZ = 0, the data size mentioned the sequence pointed to by the SEQID field overrides this value. SW should ensure that this transfer size is not greater than the size of this buffer.

*Table continues on the next page...*

## QuadSPIx\_BUF1CR field descriptions (continued)

Field	Description
7–4 Reserved	This field is reserved.
MSTRID	Master ID: The ID of the AHB master associated with BUFFER1. Any AHB access with this master port number is routed to this buffer.

## 10.2.14.6 Buffer2 Configuration Register (QuadSPIx\_BUF2CR)

This register provides the configuration for any access to buffer2. An access is routed to buffer2 when the master port number of the incoming AHB request matches the MSTRID field of the BUF2CR. Any buffer "miss" leads to the buffer being flushed and a serial flash transaction being triggered as per the sequence pointed to by the SEQID field.

*Write:*

- $QSPI\_SR[AHB\_ACC] = 0$

Address: Base address + 18h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved																ADATSZ				Reserved			MSTRID								
W	Reserved																ADATSZ				Reserved			MSTRID								
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

## QuadSPIx\_BUF2CR field descriptions

Field	Description
31–16 Reserved	This field is reserved. Reserved.
15–8 ADATSZ	AHB data transfer size: Defines the data transfer size in 8 Bytes of an AHB triggered access to serial flash. For example, a value of 0x2 will set transfer size to 16bytes. When ADATSZ = 0, the data size mentioned the sequence pointed to by the SEQID field overrides this value. SW should ensure that this transfer size is not greater than the size of this buffer.
7–4 Reserved	This field is reserved. Reserved.
MSTRID	Master ID: The ID of the AHB master associated with BUFFER2. Any AHB access with this master port number is routed to this buffer.

### 10.2.14.7 Buffer3 Configuration Register (QuadSPIx\_BUF3CR)

This register provides the configuration for any access to buffer3. An access is routed to buffer3 when the master port number of the incoming AHB request matches the MSTRID field of the BUF3CR. Any buffer "miss" leads to the buffer being flushed a serial flash transaction being triggered as per the sequence pointed to by the SEQID field. If the ALLMST field is set, any transaction where the master port number does not match any of the buffer MSTRID fields will be routed to this buffer. In the case that the ALLMST field is not set, any such transaction (where master port number does not match any of the MSTRID fields) will be returned an ERROR response.

Write:

- $QSPI\_SR[AHB\_ACC] = 0$

Address: Base address + 1Ch offset

#### QuadSPIx\_BUF3CR field descriptions

Field	Description
31 ALLMST	All master enable: When set, buffer3 acts as an all-master buffer. Any AHB access with a master port number not matching with the master ID of buffer0 or buffer1 or buffer2 is routed to buffer3. When set, the MSTRID field of this register is ignored.
30–16 Reserved	This field is reserved. Reserved.
15–8 ADATSZ	AHB data transfer size: Defines the data transfer size in 8 Bytes of an AHB triggered access to serial flash. When ADATSZ = 0, the data size mentioned the sequence pointed to by the SEQID field overrides this value. SW should ensure that this transfer size is not greater than the size of this buffer.
7–4 Reserved	This field is reserved.
MSTRID	Master ID: The ID of the AHB master associated with BUFFER3. Any AHB access with this master port number is routed to this buffer.

### 10.2.14.8 Buffer Generic Configuration Register (QuadSPIx\_BFGENCR)

This register provides the generic configuration to any of the buffer accesses. Any buffer "miss" leads to the buffer being flushed and a serial flash transaction being triggered as per the sequence pointed to by the SEQID field. If the PAR\_EN field is set, all the buffer accesses result in parallel accesses to the flashes.

*Write:*

- $QSPI\_SR[AHB\_ACC] = 0$

Address: Base address + 20h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved															PAR_EN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	SEQID				Reserved											
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### QuadSPIx\_BFGENCR field descriptions

Field	Description
31–17 Reserved	This field is reserved.
16 PAR_EN	When set, a transaction to two serial flash devices is triggered in parallel mode. Refer to <a href="#">Parallel Flash Mode</a> for more details.
15–12 SEQID	Points to a sequence in the Look-up-table. The SEQID defines the bits [6:2] of the LUT index. The bits [1:0] are always assumed to be 0. Refer to <a href="#">Look-up Table</a> .  <b>NOTE:</b> If the sequence pointer differs between the new and previous sequence then the user should reset this. See QSPI_SPTRCLR for more information.
Reserved	This field is reserved.

### 10.2.14.9 Buffer0 Top Index Register (QuadSPIx\_BUF0IND)

This register specifies the top index of buffer0, which defines its size. Note that the 3 LSBs of this register are set to zero - this ensures that the buffer is 64bit aligned, as each buffer entry is 64bits long.

The register value should be set to the desired number of bytes less 8. For example, setting BUF0IND to 0 gives 8 bytes, 1 give 16bytes etc.

The size of buffer0 is the difference between the BUF0IND+8 and 0.

It is the responsibility of the software to ensure that BUF0IND value is not greater than the overall size of the buffer. The hardware does not provide any protection against illegal programming.

Write:

- $QSPI\_SR[AHB\_ACC] = 0$

Address: Base address + 30h offset

#### QuadSPIx\_BUF0IND field descriptions

Field	Description
31-3 TPINDX0	Top index of buffer 0.
Reserved	This field is reserved. Reserved.

### 10.2.14.10 Buffer1 Top Index Register (QuadSPIx\_BUF1IND)

This register specifies the top index of buffer1, which defines its size. Note that the 3 LSBs of this register are set to zero - this ensures that the buffer is 64bit aligned as each buffer entry is 64bits long.

The register value should be set to the desired number of bytes less. The size of buffer1 is the difference between the BUF1IND and BUF0IND.

It is the responsibility of the software to ensure that BUF1IND value is not greater than the overall size of the buffer. The hardware does not provide any protection against illegal programming.

Write:

- $QSPI\_SR[AHB\_ACC] = 0$

Address: Base address + 34h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### QuadSPIx\_BUF1IND field descriptions

Field	Description
31–3 TPINDEX1	Top index of buffer 1.
Reserved	This field is reserved.

#### 10.2.14.11 Buffer2 Top Index Register (QuadSPIx\_BUF2IND)

This register specifies the top index of buffer2, which defines its size. Note that the 3 LSBs of this register are set to zero - this ensures that the buffer is 64bit aligned as each buffer entry is 64bits long.

The register value should be set to the desired number of bytes less 8. The size of buffer2 is the difference between the BUF2IND and BUF1IND.

It is the responsibility of the software to ensure that BUF2IND value is not greater than the overall size of the buffer. The hardware does not provide any protection against illegal programming.

Write:

- $QSPI\_SR[AHB\_ACC] = 0$

Address: Base address + 38h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	TPINDEX2																Reserved

#### QuadSPIx\_BUF2IND field descriptions

Field	Description
31–3 TPINDEX2	Top index of buffer 2.
Reserved	This field is reserved.

### 10.2.14.12 Serial Flash Address Register (QuadSPIx\_SFAR)

The module automatically translates this address on the memory map to the address on the flash itself. When operating in 24bit mode, only bits 23-0 are sent to the flash, in 32bit mode, bits 27-0 are used with bits 31-28 driven to 0 Refer to [Table 10-7](#) for the mapping between the access mode and the QSPI\_SFAR content and to [Normal Mode](#) for details about the command triggering and command execution. The software should ensure that the serial flash address provided in the QSPI\_SFAR register lies in the valid flash address range as defined in [Table 10-7](#).

*Write:*

- $QSPI\_SR[IP\_ACC] = 0$

Address: Base address + 100h offset

#### QuadSPIx\_SFAR field descriptions

Field	Description
SFADR	Serial Flash Address. The register content is used as byte address for all following IP Commands.

### 10.2.14.13 Sampling Register (QuadSPIx\_SMPR)

The Sampling Register allows configuration of how the incoming data from the external serial flash devices are sampled in the QuadSPI module.

*Write: Disabled Mode*

Address: Base address + 108h offset

## QuadSPIx\_SMPR field descriptions

Field	Description
31–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–16 DDRSMP	DDR Sampling point. Select the sampling point for incoming data when serial flash is executing a DDR instruction. Refer to <a href="#">Input timing in DDR mode with internal sampling</a> , for details on the sampling points.
15–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–5 SDRSMP	SDR sampling point.
4–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

## 10.2.14.14 RX Buffer Status Register (QuadSPIx\_RBSR)

This register contains information related to the receive data buffer.

Address: Base address + 10Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	RDCTR															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved		RDBFL						Reserved							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

## QuadSPIx\_RBSR field descriptions

Field	Description
31–16 RDCTR	Read Counter, indicates how many entries of 4 bytes have been removed from the RX Buffer. For example a value of 0x2 would indicate 8bytes have been removed  It is incremented by the number (QSPI_RBCT[WMRK] + 1) on RX Buffer POP event. The RX Buffer can be popped using DMA or pop flag QSPI_FR[RBDF]. The QSPI_RSER[RBDE] defines which pop has to be done. For further details please refer to <a href="#">AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31)</a> and "Data Transfer from the QuadSPI Module Internal Buffers section in <a href="#">Flash Read</a> section.
15–14 Reserved	This field is reserved.
13–8 RDBFL	RX Buffer Fill Level, indicates how many entries of 4 bytes are still available in the RX Buffer. For example a value of 0x2 would indicate 8bytes are available.
Reserved	This field is reserved.

### 10.2.14.15 RX Buffer Control Register (QuadSPIx\_RBCT)

This register contains control data related to the receive data buffer.

*Write:*

- $QSPI\_SR[IP\_ACC] = 0$

Address: Base address + 110h offset

#### QuadSPIx\_RBCT field descriptions

Field	Description
31–9 Reserved	This field is reserved.
8 RXBRD	RX Buffer Readout: This bit specifies the access scheme for the RX Buffer readout. 0 RX Buffer content is read using the AHB Bus registers QSPI_ARDB0 to QSPI_ARDB31. For details, refer to <a href="#">Exclusive Access to Serial Flash for AHB Commands</a> . 1 RX Buffer content is read using the IP Bus registers QSPI_RBDR0 to QSPI_RBDR31.
7–5 Reserved	This field is reserved.
WMRK	RX Buffer Watermark: This field determines when the readout action of the RX Buffer is triggered. When the number of valid entries in the RX Buffer is equal to or greater than the number given by (WMRK+1) the QSPI_SR[RXWE] flag is asserted. The value should be entered as the number of 4byte entries minus 1. For example a value of 0x0 would set the watermark to 4bytes, 1 to 8bytes, 2 to 12bytes etc. For details, refer to <a href="#">DMA Usage</a> .

### 10.2.14.16 TX Buffer Status Register (QuadSPIx\_TBSR)

This register contains information related to the transmit data buffer.

Address: Base address + 150h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	TRCTR																Reserved			TRBFL				Reserved								
W	0																0			0				0								
Reset	0																0			0				0								

#### QuadSPIx\_TBSR field descriptions

Field	Description
31–16 TRCTR	Transmit Counter. This field indicates how many entries of 4 bytes have been written into the TX Buffer by host accesses. It is reset to 0 when a 1 is written into the QSPI_MCR[CLR_TXF] bit. It is incremented on each write access to the QSPI_TBDR register when another word has been pushed onto the TX Buffer. When it is not cleared the TRCTR field wraps around to 0. Refer to <a href="#">TX Buffer Data Register (QuadSPI_TBDR)</a> for details.
15–13 Reserved	This field is reserved.
12–8 TRBFL	TX Buffer Fill Level. The TRBFL field contains the number of entries of 4 bytes each available in the TX Buffer for the QuadSPI module to transmit to the serial flash device.
Reserved	This field is reserved.

### 10.2.14.17 TX Buffer Data Register (QuadSPIx\_TBDR)

The QSPI\_TBDR register provides access to the circular TX Buffer of depth 128 bytes. This buffer provides the data written into it as write data for the page programming commands to the serial flash device. Refer to [Table 10-16](#) for the byte ordering scheme. A write transaction on the flash with data size of less than 32 bits will lead to the removal of four data entry from the TX buffer. The valid bits will be used and the rest of the bits will be discarded.

Write:

- $QSPI\_SR[TXFULL] = 0$

*32-bit write access required*

**NOTE**

There is no limitation on Flash programming size. But the data size written to TX Buffer should be 64 Byte aligned. If flash programming size is not 64 bytes aligned, please write redundant data to TX Buffers. The redundant data will be ignored by QuadSPI controller.

Address: Base address + 154h offset

**QuadSPIx\_TBDR field descriptions**

Field	Description
TXDATA	<p>TX Data</p> <p>On write access the data is written into the next available entry of the TX Buffer and the QPSI_TBSR[TRBFL] field is updated accordingly.</p> <p>On a read access, the last data written to the register is returned.</p>

### 10.2.14.18 Status Register (QuadSPiX\_SR)

The QSPI\_SR register provides all available status information about SFM command execution and arbitration, the RX Buffer and TX Buffer and the AHB Buffer.

Address: Base address + 15Ch offset

## AHB RX Data Buffer (QSPI\_ARDB0 to QSPI\_ARDB31)

### QuadSPiX\_SR field descriptions

Field	Description
31–29 DLPSMP	<p><b>NOTE:</b> Data learning is not implemented on this chip. Data learning pattern sampling point: The sampling point found by the controller with the data learning pattern.</p> <ul style="list-style-type: none"> <li>This is used for DDR only.</li> <li>If the learning fails, this field will return garbage and DLPFF bit will be set.</li> <li></li> </ul>
28 Reserved	This field is reserved.
27 TXFULL	TX Buffer Full: Asserted when no more data can be stored.
26 Reserved	This field is reserved.
25 Reserved	This field is reserved.
24 TXEDA	<p>Tx Buffer Enough Data Available</p> <p>Asserted when TX Buffer contains enough data for any pop operation to take place. There must be atleast 128bit data available in TX FIFO for any pop operation otherwise QSPI_FR[TBUF] will be set.</p>

Table continues on the next page...

## QuadSPIx\_SR field descriptions (continued)

Field	Description
23 RXDMA	RX Buffer DMA: Asserted when RX Buffer read out via DMA is active i.e DMA is requested or running.
22–20 Reserved	This field is reserved.
19 RXFULL	RX Buffer Full: Asserted when the RX Buffer is full, i.e. that QSPI_RBSR[RDBFL] field is equal to 32.
18–17 Reserved	This field is reserved.
16 RXWE	RX Buffer Watermark Exceeded: Asserted when the number of valid entries in the RX Buffer exceeds the number given in the QSPI_RBCT[WMRK] field.
15 Reserved	This field is reserved.
14 AHB3FUL	AHB 3 Buffer Full: Asserted when AHB 3 buffer is full.
13 AHB2FUL	AHB 2 Buffer Full: Asserted when AHB 2 buffer is full.
12 AHB1FUL	AHB 1 Buffer Full: Asserted when AHB 1 buffer is full.
11 AHB0FUL	AHB 0 Buffer Full: Asserted when AHB 0 buffer is full.
10 AHB3NE	AHB 3 Buffer Not Empty: Asserted when AHB 3 buffer contains data.
9 AHB2NE	AHB 2 Buffer Not Empty: Asserted when AHB 2 buffer contains data.
8 AHB1NE	AHB 1 Buffer Not Empty: Asserted when AHB 1 buffer contains data.
7 AHB0NE	AHB 0 Buffer Not Empty: Asserted when AHB 0 buffer contains data.
6 AHBTRN	AHB Access Transaction pending: Asserted when there is a pending request on the AHB interface. Refer to the AMBA specification for details.
5 AHBGNT	AHB Command priority Granted: Asserted when another module has been granted priority of AHB Commands against IP Commands. For details refer to <a href="#">Command Arbitration</a> .
4 Reserved	This field is reserved.
3 RESERVED	This field is reserved.
2 AHB_ACC	AHB Access: Asserted when the transaction currently executed was initiated by AHB bus.
1 IP_ACC	IP Access: Asserted when transaction currently executed was initiated by IP bus.
0 BUSY	Module Busy: Asserted when module is currently busy handling a transaction to an external flash device.

### 10.2.14.19 Flag Register (QuadSPIx\_FR)

The QSPI\_FR register provides all available flags about SFM command execution and arbitration which may serve as source for the generation of interrupt service requests. Note that the error flags in this register do not relate directly to the execution of the transaction in the serial flash device itself but only to the behavior and conditions visible in the QuadSPI module.

*Write: Enabled Mode*

Address: Base address + 160h offset

### QuadSPiX\_FR field descriptions

Field	Description
31 DLFFF	<b>NOTE:</b> Data learning is not implemented on this chip. Data Learning Pattern Failure Flag: Set when DATA_LEARN instruction was encountered in a sequence but no sampling point was found for the data learning pattern The controller automatically starts sampling using the value in QSPI_SMPR[DDRSMP].
30 Reserved	This field is reserved.
29–28 Reserved	This field is reserved.
27 TBFF	TX Buffer Fill Flag: Before writing to the TX buffer, this bit should be cleared. Then this bit has to be read back. If the bit is set, the TX Buffer can take more data. If the bit remains cleared, the TX buffer is full. Refer to <a href="#">Tx Buffer Operation</a> for details.
26 TBUF	TX Buffer Underrun Flag: Set when the module tried to pull data although TX Buffer was empty or the buffer contains less than 128bits of data. The application must ensure that the buffer never goes empty during a transaction expect for the last data fetch. The IP Command leading to the TX Buffer underrun is continued (data sent to the serial flash device is all F in case of valid tx underrun. The application must clear the TX Buffer in response to this event by writing a 1 into the QSPI_MCR[CLR_TXF] bit.
25–24 Reserved	This field is reserved.
23 ILLINE	Illegal Instruction Error Flag: Set when an illegal instruction is encountered by the controller in any of the sequences. Refer to <a href="#">Table 10-14</a> for a list of legal instructions.
22–18 Reserved	This field is reserved.
17 RBOF	RX Buffer Overflow Flag: Set when not all the data read from the serial flash device could be pushed into the RX Buffer.  The IP Command leading to this condition is continued until the number of bytes according to the QSPI_IPCR[IDATSZ] field has been read from the serial flash device.

Table continues on the next page...

**QuadSPIx\_FR field descriptions (continued)**

Field	Description
	The content of the RX Buffer is not changed.
16 RBDF	<p>RX Buffer Drain Flag: Will be set if the QuadSPI_SR[RXWE] status bit is asserted.</p> <p>Writing 1 into this bit triggers one of the following actions:</p> <ul style="list-style-type: none"> <li>• If the RX Buffer has up to QuadSPI_RBCT[WMRK] valid entries then the flag is cleared.</li> <li>• If the RX Buffer has more than QuadSPI_RBCT[WMRK] valid entries and the QuadSPI_RSER[RBDDE] bit is not set (flag driven mode) a RX Buffer POP event is triggered.</li> </ul> <p>The flag remains set if the RX Buffer contains more than QuadSPI_RBCT[WMRK] valid entries after the RX Buffer POP event is finished.</p> <p>The flag is cleared if the RX Buffer contains less than or equal to QuadSPI_RBCT[WMRK] valid entries after the RX Buffer POP event is finished.</p> <p>Refer to "Receive Buffer Drain Interrupt or DMA Request" section in <a href="#">Normal Mode Interrupt and DMA Requests</a>, for details.</p>
15 ABSEF	<p>AHB Sequence Error Flag: Set when the execution of an AHB Command is started with an WRITE or WRITE_DDR Command in the sequence pointed to by the QSPI_BUFxCR register</p> <p>Communication with the serial flash device is terminated before the execution of WRITE/WRITE_DDR command by the QuadSPI module.</p> <p>The AHB bus request which triggered this command is answered with an ERROR response.</p>
14 Reserved	<p>Reserved</p> <p>This field is reserved.</p>
13 Reserved	<p>Reserved</p> <p>This field is reserved.</p>
12 ABOF	<p>AHB Buffer Overflow Flag: Set when the size of the AHB access exceeds the size of the AHB buffer. This condition can occur only if the QSPI_BUFxCR[ADATSZ] field is programmed incorrectly.</p> <p>The AHB Command leading to this condition is continued until the number of entries according to the QSPI_BUFxCR[ADATSZ] field has been read from the serial flash device.</p> <p>The content of the AHB Buffer is not changed.</p>
11 IUEF	<p>IP Command Usage Error Flag: Set when in parallel flash mode the execution of an IP Command is started and the sequence pointed to by the sequence ID contains a WRITE or a WRITE_DDR command. Refer to <a href="#">Table 10-14</a> table for the related commands.</p> <p>Communication with the serial flash device is terminated before the execution of WRITE/WRITE_DDR command by the QuadSPI module.</p>
10–8 Reserved	This field is reserved.
7 IPAIEF	<p>IP Command Trigger during AHB Access Error Flag. Set when the following condition occurs:</p> <ul style="list-style-type: none"> <li>• A write access occurs to the QSPI_IPCR[SEQID] field and the QSPI_SR[AHB_ACC] bit is set. Any command leading to the assertion of the IPAIEF flag is ignored.</li> </ul>
6 IPIEF	<p>IP Command Trigger could not be executed Error Flag. Set when the QSPI_SR[IP_ACC] bit is set (i.e. an IP triggered command is currently executing) and any of the following conditions occurs:</p> <ul style="list-style-type: none"> <li>• Write access to the QSPI_IPCR register. Any command leading to the assertion of the IPIEF flag is ignored</li> <li>• Write access to the QSPI_SFAR register.</li> <li>• Write access to the QSPI_RBCT register.</li> </ul>
5 Reserved	This field is reserved.

Table continues on the next page...

## QuadSPIx\_FR field descriptions (continued)

Field	Description
4 IPGEF	IP Command Trigger during AHB Grant Error Flag: Set when the following condition occurs: <ul style="list-style-type: none"> <li>A write access occurs to the QSPI_IPCR[SEQID] field and the QSPI_SR[AHBGNT] bit is set. Any command leading to the assertion of the IPGEF flag is ignored.</li> </ul>
3–1 Reserved	This field is reserved.
0 TFF	IP Command Transaction Finished Flag: Set when the QuadSPI module has finished a running IP Command. If an error occurred the related error flags are valid, at the latest, in the same clock cycle when the TFF flag is asserted.

1. QSPI\_BUFxCR implies anyone of QSPI\_BUF0CR/QSPI\_BUF1CR/QSPI\_BUF2CR/QSPI\_BUF3CR

### 10.2.14.20 Interrupt and DMA Request Select and Enable Register (QuadSPIx\_RSER)

The QuadSPI\_RSER register provides enables and selectors for the interrupts in the QuadSPI module.

#### NOTE

Each flag of the QuadSPI\_FR register enabled as source for an interrupt prevents the QuadSPI module from entering Stop Mode or Module Disable Mode when this flag is set.

>

### 10.2.14.21 Sequence Suspend Status Register (QuadSPIx\_SPNDST)

The sequence suspend status register provides information specific to any suspended sequence. An AHB sequence may be suspended when a high priority AHB master makes an access before the AHB sequence completes the data transfer requested.

Address: Base address + 168h offset

**QuadSPiX\_SPNDST field descriptions**

Field	Description
31–16 Reserved	This field is reserved.
15–9 DATLFT	Data left: Provides information about the amount of data left to be read in the suspended sequence. Valid only when SUSPND is set to 1'b1. Value in terms of 64 bits or 8 bytes
8 Reserved	This field is reserved.
7–6 SPDBUF	Suspended Buffer: Provides the suspended buffer number. Valid only when SUSPND is set to 1'b1
5–1 Reserved	This field is reserved.
0 SUSPND	When set, it signifies that a sequence is in suspended state

### 10.2.14.22 Sequence Pointer Clear Register (QuadSPIx\_SPTRCLR)

The sequence pointer clear register provides bits to reset the IP and Buffer sequence pointers. The sequence pointer contains the index of which instruction within the LUT entry is to be executed next. For example, if the LUT entry ends on a JMP\_ON\_CS value of 2, the index will be stored as 2.

The software should reset the sequence pointers whenever the sequence ID is changed by updating the SEQID field in QSPI\_IPCR or QSPI\_BFGENCR.

Address: Base address + 16Ch offset

**QuadSPIx\_SPTRCLR field descriptions**

Field	Description
31–9 Reserved	This field is reserved.
8 IPPTRC	IP Pointer Clear: 1: Clears the sequence pointer for IP accesses as defined in QuadSPI_IPCR
7–1 Reserved	This field is reserved. Reserved.
0 BFPTRC	Buffer Pointer Clear: 1: Clears the sequence pointer for AHB accesses as defined in QuadSPI_BFGENCR.

### 10.2.14.23 Serial Flash A1 Top Address (QuadSPIx\_SFA1AD)

The QSPI\_SFA1AD register provides the address mapping for the serial flash A1. The difference between QSPI\_SFA1AD[TPADA1] and QSPI\_AMBA\_BASE defines the size of the memory map for serial flash A1.

*Write:*

- $QSPI\_SR[IP\_ACC] = 0$
- $QSPI\_SR[AHB\_ACC] = 0$

Address: Base address + 180h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### QuadSPIx\_SFA1AD field descriptions

Field	Description
31–10 TPADA1	Top address for Serial Flash A1. In effect, TPADxx is the first location of the next memory.
Reserved	This field is reserved.

#### 10.2.14.24 Serial Flash A2 Top Address (QuadSPIx\_SFA2AD)

The QSPI\_SFA2AD register provides the address mapping for the serial flash A2. The difference between QSPI\_SFA2AD[TPADA2] and QSPI\_SFA1AD[TPADA1] defines the size of the memory map for serial flash A2.

*Write:*

- $QSPI\_SR[IP\_ACC] = 0$
- $QSPI\_SR[AHB\_ACC] = 0$

Address: Base address + 184h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	TPADA2																Reserved															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### QuadSPIx\_SFA2AD field descriptions

Field	Description
31–10 TPADA2	Top address for Serial Flash A2. In effect, TPxxAD is the first location of the next memory.
Reserved	This field is reserved.

#### 10.2.14.25 Serial Flash B1 Top Address (QuadSPIx\_SFB1AD)

The QSPI\_SFB1AD register provides the address mapping for the serial flash B1. The difference between QSPI\_SFB1AD[TPADB1] and QSPI\_SFA2AD[TPADA2] defines the size of the memory map for serial flash B1.

*Write:*

## AHB RX Data Buffer (QSPI\_ARDB0 to QSPI\_ARDB31)

- $QSPI\_SR[IP\_ACC] = 0$
- $QSPI\_SR[AHB\_ACC] = 0$

Address: Base address + 188h offset

### QuadSPIx\_SFB1AD field descriptions

Field	Description
31–10 TPADB1	Top address for Serial Flash B1. In effect, TPxxAD is the first location of the next memory.
Reserved	This field is reserved.

## 10.2.14.26 Serial Flash B2Top Address (QuadSPIx\_SFB2AD)

The QSPI\_SFB2AD register provides the address mapping for the serial flash B2. The difference between QSPI\_SFB2AD[TPADB2] and QSPI\_SFB1AD[TPADB1] defines the size of the memory map for serial flash B2.

*Write:*

- $QSPI\_SR[IP\_ACC] = 0$
- $QSPI\_SR[AHB\_ACC] = 0$

Address: Base address + 18Ch offset

### QuadSPIx\_SFB2AD field descriptions

Field	Description
31–10 TPADB2	Top address for Serial Flash B2. In effect, TPxxAD is the first location of the next memory.
Reserved	This field is reserved.

## 10.2.14.27 RX Buffer Data Register (QuadSPIx\_RBDRn)

The QuadSPI\_RBDR registers provide access to the individual entries in the RX Buffer. Refer to [Table 10-16](#) for the byte ordering scheme.

QuadSPI\_RBDR0 corresponds to the actual position of the read pointer within the RX Buffer. The number of valid entries available depends from the number of RX Buffer entries implemented and from the number of valid buffer entries available in the RX Buffer.

Example 1, RX Buffer filled completely with 32 words: In this case the address range for valid read access extends from QuadSPI\_RBDR0 to QuadSPI\_RBDR31.

Example 2, RX Buffer filled with 5 valid words: RX Buffer fill level QuadSPI\_RBSR[RDBFL] is 5. In this case an access to QuadSPI\_RBDR4 provides the last valid entry.

Any access beyond the range of valid RX Buffer entries provides undefined results.

Address: Base address + 200h offset + (4d × i), where i=0d to 31d

### QuadSPIx\_RBDRn field descriptions

Field	Description
RXDATA	RX Data. The RXDATA field contains the data associated with the related RX Buffer entry. Data format and byte ordering is given in <a href="#">Byte Ordering of Serial Flash Read Data</a> .

### 10.2.14.28 LUT Key Register (QuadSPIx\_LUTKEY)

The LUT Key register contains the key to lock and unlock the Look-up-table. Refer to [Look-up Table](#) for details.

*Write: Anytime*

Address: Base address + 300h offset

### QuadSPIx\_LUTKEY field descriptions

Field	Description
KEY	The key to lock or unlock the LUT. The KEY is 0x5AF05AF0. The read value is always 0x5AF05AF0

### 10.2.14.29 LUT Lock Configuration Register (QuadSPiX\_LCKCR)

The LUT lock configuration register is used along with QSPI\_LUTKEY register to lock or unlock the LUT. This register has to be written immediately after QSPI\_LUTKEY register for the lock or unlock operation to be successful. Refer to [Look-up Table](#) for details. Setting both the LOCK and UNLOCK bits as "00" or "11" is not allowed.

*Write: Just after writing the LUT Key Register*

*(QSPI\_LUTKEY)*

Address: Base address + 304h offset

**QuadSPiX\_LCKCR field descriptions**

Field	Description
31–2 Reserved	This field is reserved.
1 UNLOCK	Unlocks the LUT when the following two conditions are met: <ol style="list-style-type: none"> <li>1. This register is written just after the <a href="#">LUT Key Register (QuadSPI_LUTKEY)</a></li> <li>2. The LUT key register was written with 0x5AF05AF0 key</li> </ol>
0 LOCK	Locks the LUT when the following condition is met: <ol style="list-style-type: none"> <li>1. This register is written just after the <a href="#">LUT Key Register (QuadSPI_LUTKEY)</a></li> <li>2. The LUT key register was written with 0x5AF05AF0 key</li> </ol>

### 10.2.14.30 Look-up Table register (QuadSPiX\_LUT0)

The LUT registers are a look-up-table for sequences of instructions. The programmable sequence engine executes the instructions in these sequences to generate a valid serial flash transaction. There are a total of 64 LUT registers. These 64 registers are divided into groups of 4 registers that make a valid sequence. Therefore, QSPI\_LUT[0], QSPI\_LUT[4], QSPI\_LUT[8] ..... QSPI\_LUT[60] are the starting registers of a valid sequence. Each of these sets of 4 registers can have a maximum of 8 instructions. A maximum of 16 sequences can be defined at one time. [Look-up Table](#) describes the LUT registers in detail.

*Write: Once the LUT is unlocked*

Address: Base address + 310h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W	INSTR0								PAD0		OPRND0					
Reset	0	0	0	0	0	1	0	0	0	0	0	0	0	0	1	1

#### QuadSPiX\_LUT0 field descriptions

Field	Description
31–26 INSTR1	Instruction 1
25–24 PAD1	Pad information for INSTR1. 00 1 Pad 01 2 Pads 10 4 Pads 11 NA
23–16 OPRND1	Operand for INSTR1.
15–10 INSTR0	Instruction 0
9–8 PAD0	Pad information for INSTR0. 00 1 Pad 01 2 Pads 10 4 Pads 11 NA
OPRND0	Operand for INSTR0.

### 10.2.14.31 Look-up Table register (QuadSPiX\_LUT1)

The LUT registers are a look-up-table for sequences of instructions. The programmable sequence engine executes the instructions in these sequences to generate a valid serial flash transaction. There are a total of 64 LUT registers. These 64 registers are divided into groups of 4 registers that make a valid sequence. Therefore, QSPI\_LUT[0], QSPI\_LUT[4], QSPI\_LUT[8] ..... QSPI\_LUT[60] are the starting registers of a valid sequence. Each of these sets of 4 registers can have a maximum of 8 instructions. A maximum of 16 sequences can be defined at one time. [Look-up Table](#) describes the LUT registers in detail.

*Write: Once the LUT is unlocked*

## 10.3 Ultra Secured Digital Host Controller (uSDHC)

### 10.3.1 Overview

The Ultra Secured Digital Host Controller (uSDHC) provides the interface between the host system and the SD/SDIO/MMC cards, as depicted in [Figure 10-35](#).

The uSDHC acts as a bridge, passing host bus transactions to the SD/SDIO/MMC cards by sending commands and performing data accesses to/from the cards.

It handles the SD/SDIO/MMC protocols at the transmission level.

The following are brief descriptions of the cards supported by the uSDHC:

The Multi Media Card (MMC) is a universal low cost data storage and communication media designed to cover a wide array of applications including mobile video and gaming. Previous MMC cards were based on a 7-pin serial bus with a single data pin, while the new high speed MMC communication is based on an advanced 11-pin serial bus designed to operate in the low voltage range.

The Secure Digital Card (SD) is an evolution of the old MMC technology. It is specifically designed to meet the security, capacity, performance, and environment requirements inherent in newly-emerging audio and video consumer electronic devices. The physical form factor, pin assignment and data transfer protocol are forward-compatible with the old MMC (with some additions).

Under the SD protocol, it can be categorized into Memory card, I/O card and Combo card, which has both memory and I/O functions. The memory card invokes a copyright protection mechanism that complies with the security of the SDMI standard. The I/O card, which is also known as SDIO card, provides high-speed data I/O with low power consumption for mobile electronic devices. For the sake of simplicity, the following figure does not show cards with reduced size or mini cards.

Figure 10-35. System Connection of the uSDHC

Figure 10-36. ultra Secure Digital Host Controller Block Diagram

### 10.3.1.1 Features

The features of the uSDHC module include the following:

- Conforms to the SD Host Controller Standard Specification version 3.0
- Compatible with the MMC System Specification version 4.2/4.3/4.4/4.41/4.5/5.0
- Compatible with the SD Memory Card Specification version 3.0 and supports the Extended Capacity SD Memory Card
- Compatible with the SDIO Card Specification version 3.0
- Designed to work with SD Memory, miniSD Memory, SDIO, miniSDIO, SD Combo, MMC, MMC plus, and MMC RS cards
- Card bus clock frequency up to 208 MHz
- Supports 1-bit / 4-bit SD and SDIO modes, 1-bit / 4-bit / 8-bit MMC modes
  - Up to 832 Mbps of data transfer for SDIO cards using 4 parallel data lines in SDR(Single Data Rate) mode
  - Up to 400 Mbps of data transfer for SDIO card using 4 parallel data lines in DDR(Dual Data Rate) mode
  - Up to 832 Mbps of data transfer for SDXC cards using 4 parallel data lines in SDR(Single Data Rate) mode
  - Up to 400 Mbps of data transfer for SDXC card using 4 parallel data lines in DDR(Dual Data Rate) mode
  - Up to 1600 Mbps of data transfer for MMC cards using 8 parallel data lines in SDR(Single Data Rate) mode
  - Up to 3200 Mbps of data transfer for MMC cards using 8 parallel data lines in DDR(Dual Data Rate) mode
- Supports single block/multi-block read and write
- Supports block sizes of 1 ~ 4096 bytes
- Supports the write protection switch for write operations
- Supports both synchronous and asynchronous abort
- Supports pause during the data transfer at block gap
- Supports SDIO Read Wait and Suspend Resume operations
- Supports Auto CMD12 for multi-block transfer
- Host can initiate non-data transfer command while data transfer is in progress
- Allows cards to interrupt the host in 1-bit and 4-bit SDIO modes, also supports interrupt period
- Embodies a fully configurable 128x32-bit FIFO for read/write data
- Supports internal and external DMA capabilities
- Support voltage selection by configuring vendor specific register bit
- Supports Advanced DMA to perform linked memory access

## 10.3.1.2 Modes and Operations

### 10.3.1.2.1 Data transfer Modes

The uSDHC can select the following modes for data transfer:

- SD 1-bit
- SD 4-bit
- MMC 1-bit
- MMC 4-bit
- MMC 8-bit
- Identification Mode (up to 400 kHz)
- MMC full speed mode (up to 26 MHz)
- MMC high speed mode (up to 52 MHz)
- MMC HS400 mode (200 MHz both edges)
- MMC DDR mode (52 MHz both edges)
- SD/SDIO full speed mode (up to 25 MHz)
- SD/SDIO high speed mode (up to 50 MHz)
- SD/SDIO UHS-I mode (up to 208 MHz in SDR mode, up to 50 MHz in DDR mode)

## 10.3.2 External Signals

The following table describes the external signals of USDHC:

**Table 10-40. USDHC External Signals**

Signal	Description	Pad	Mode	Direction
SD1_CD_B	Card detection pin If not used(for the embedded memory),tie low to indicate there is a card attached.	SD1_CD_B	ALT0	I
SD1_CLK	Clock for MMC/SD/SDIO card	SD1_CLK	ALT0	O
SD1_CMD	CMD line connect to card	SD1_CMD	ALT0	IO
SD1_DATA0	DATA0 line in all modes Also used to detect busy state	SD1_DATA0	ALT0	IO
SD1_DATA1	DATA1 line in 4/8-bit mode Also used to detect interrupt in 1/4- bit mode	SD1_DATA1	ALT0	IO
SD1_DATA2	DATA2 line or Read Wait in 4-bit mode. Read Wait in 1-bit mode	SD1_DATA2	ALT0	IO
SD1_DATA3	DATA3 line in 4/8-bit mode or configured as card detection pin May be configured as card detection pin in 1-bit mode	SD1_DATA3	ALT0	IO

*Table continues on the next page...*

**Table 10-40. USDHC External Signals (continued)**

Signal	Description	Pad	Mode	Direction
SD1_DATA4	DATA4 line in 8-bit mode, not used in other modes	ECSPI2_SCLK	ALT2	IO
SD1_DATA5	DATA5 line in 8-bit mode, not used in other modes	ECSPI2_MOSI	ALT2	IO

Signal	Description	Pad	Mode	Direction
	low to indicate it's not write protected.	SD3_DATA6	ALT2	

### 10.3.2.1 Signals Overview

The uSDHC has 14 associated I/O signals.

- The CLK is an internally generated clock used to drive the MMC, SD, SDIO cards.
- The CMD I/O is used to send commands and receive responses to and from the card. Eight data lines (DAT7~DAT0) are used to perform data transfers between the uSDHC and the card.
- The CD and WP are card detection and write protection signals directly routed from the socket. These two signals are active low (0). A low on CD# means that a card is inserted, and a high on WP means that the write protect switch is active.
- LCTL is an output signal used to drive an external LED to indicate that the SD interface is busy.
- RST is an output signal used to reset the MMC card.
- VSELECT is an output signal used to change the voltage of the external power supplier.

CD, WP, LCTL, RST and VSELECT are all optional for system implementation. If the uSDHC needs to support a 4-bit data transfer, DAT7~DAT4 can also be optional and tied to high.

### 10.3.3 Clocks

The table found here describes the clock sources for uSDHC.

Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

**Table 10-41. uSDHC Clocks**

Clock name	Clock Root	Description
hclk	ahb_clk_root	AHB bus clock
ipg_clk	ipg_clk_root	Peripheral clock
ipg_clk_perclk	usdhc_clk_root	Base clock
ipg_clk_s	ipg_clk_root	Peripheral access clock for register accesses

### 10.3.4 Functional Description

The following sections provide a brief functional description of the major system blocks, including the Data Buffer, DMA AHB interface, register bank as well as IP Bus interface, dual-port memory wrapper, data/command controller, clock & reset manager and clock generator.

#### 10.3.4.1 Data Buffer

The uSDHC uses one configurable data buffer to transfer data between the system bus (IP Bus or AHB Bus) and the SD card in an optimized manner, maximizing throughput between the two clock domains (IP peripheral clock and the master clock).

The buffer is used as temporary storage for data being transferred between the host system and the card. The watermark levels for read and write are both configurable and can be from 1 to 128 words. The burst lengths for read and write are also configurable and can be from 1 to 31 words.

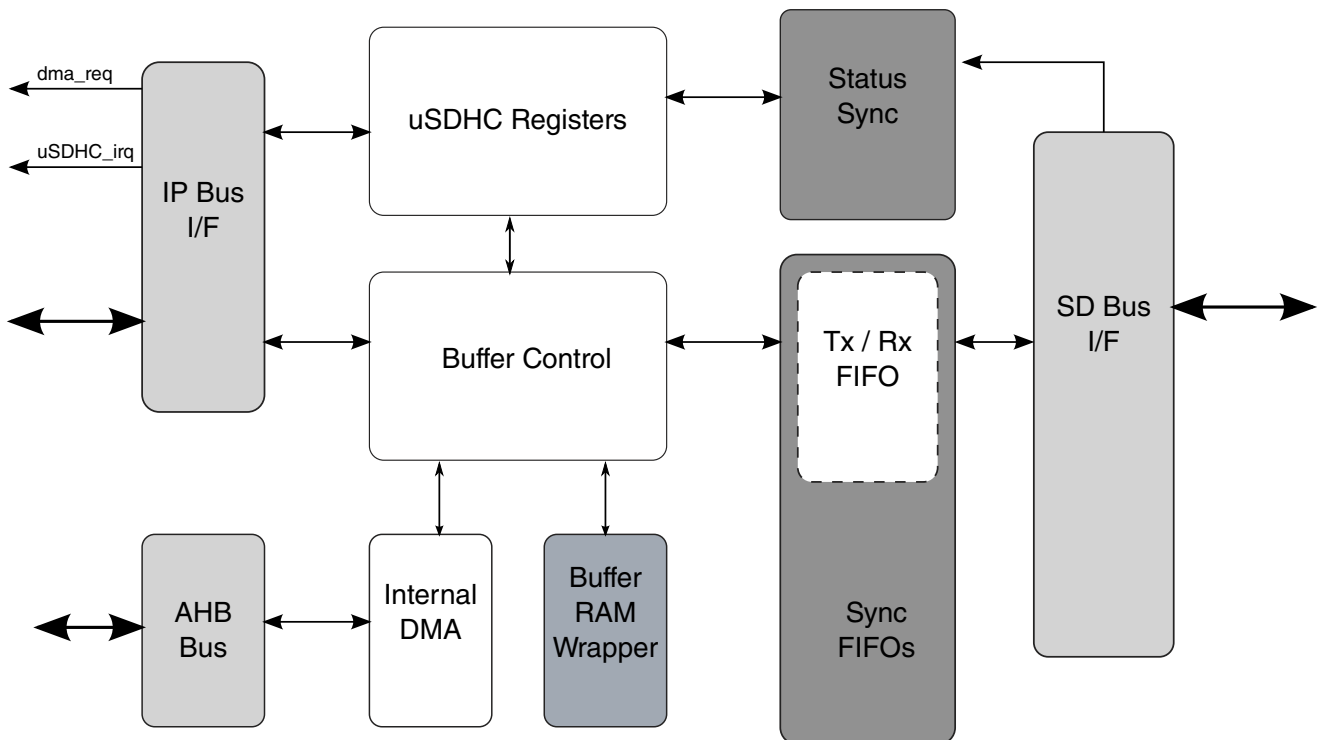

Figure 10-37. uSDHC Buffer Scheme

There are 3 transfer modes to access the data buffer:

- CPU polling mode:
  - For a host read operation, when the number of words received in the buffer meets or exceeds the RD\_WML watermark value, by polling the BRR bit, the Host Driver can read the Buffer Data Port register to fetch the amount of words set in the RD\_WML register from the buffer. The write operation is similar.
- External DMA mode:
  - For a read operation, when there are more words received in the buffer than the amount set in the RD\_WML register, a DMA request is sent out to inform the external DMA to fetch the data. The request will be immediately de-asserted when there is an access on the Buffer Data Port register. If the number of words in the buffer after the current burst meets or exceeds RD\_WML value, the DMA request is asserted again. For instance, if there are twice as many words in the buffer as there are in the RD\_WML value, there are two successive DMA requests with only one cycle of de-assertion between. The write operation is similar. Note the accesses CPU polling mode and external DMA mode both use the IP bus, and if the external DMA is enabled, in both modes an external DMA request is sent when the buffer is ready.
- Internal DMA mode (includes simple and advanced DMA accesses):
  - The internal DMA access, either by simple or advanced DMA, is over the AHB bus. For internal DMA access mode, the external DMA request will never be sent out.

For a read operation, when there are more words in the buffer than the amount set in the RD\_WML register, the internal DMA starts fetching data over the AHB bus. Except for INCR4 and INCR8, the burst type is always INCR mode and the burst length depends on the shortest of following factors:

- Burst length configured in the burst length field of the Watermark Level register
- Watermark Level boundary
- Block size boundary
- Data boundary configured in the current descriptor (if the ADMA is active)
- 1 Kbyte address boundary defined in the AHB protocol

Write operation is similar.

Sequential and contiguous access is necessary to ensure the pointer address value is correct. Random or skipped access is not possible. The byte order, by reset, is little endian mode. The actual byte order is swapped inside the buffer, according to the endian mode configured by software (see the following figures). For a host write operation, byte order is swapped after data is fetched from the buffer and ready to send to the SD Bus. For a host read operation, byte order is swapped before the data is stored in the buffer.

**Figure 10-38. Data Swap between System Bus and uSDHC Data Buffer in Byte Little Endian Mode**

**Figure 10-39. Data Swap between System Bus and uSDHC Data Buffer in Half Word Big Endian Mode**

### 10.3.4.1.1 Write Operation Sequence

There are three ways to write data into the buffer when the user transfers data to the card:

- External DMA through the uSDHC DMA request signal
- Processor core polling through the BWR bit in Interrupt Status register (interrupt or polling)
- Internal DMA

When the internal DMA is not used, (the DMAEN bit in the Transfer Type register is not set when the command is sent), the uSDHC asserts a DMA request when the amount of buffer space exceeds the value set in the WR\_WML register, and is ready for receiving new data. At the same time, the uSDHC sets the BWR bit. The buffer write ready interrupt will be generated if it is enabled by software.

When internal DMA is used, the uSDHC will not inform the system before all the required number of bytes are transferred (if no error was encountered). When an error occurs during the data transfer, the uSDHC will abort the data transfer and abandon the current block. The Host Driver should read the contents of the DMA System Address register to obtain the starting address of the abandoned data block. If the current data transfer is in multi-block mode, the uSDHC will not automatically send CMD12, even

though the AC12EN bit in the Transfer Type register is set. The Host Driver sends CMD12 in this scenario and re-starts the write operation from that address. It is recommended that a Software Reset for Data be applied before the transfer is re-started.

The uSDHC will not start data transmission until the number of words set in the WR\_WML register can be held in the buffer. If the buffer is empty and the Host System does not write data in time, the uSDHC will stop the CLK to avoid the data buffer under-run situation.

#### 10.3.4.1.2 Read Operation Sequence

There are three ways to read data from the buffer when the user transfers data to the card:

- External DMA through the uSDHC DMA request signal
- Processor core polling through the BRR bit in Interrupt Status register (interrupt or polling)
- Internal DMA

When internal DMA is not used (DMAEN bit in Transfer Type register is not set when the command is sent), the uSDHC asserts a DMA request when the amount of data exceeds the value set in the RD\_WML register, that is available and ready for system fetching data. At the same time, the uSDHC sets the BRR bit. The buffer read ready interrupt will be generated if it is enabled by software.

When internal DMA is used, the uSDHC will not inform the system before all the required number of bytes are transferred (if no error was encountered). When an error occurs during the data transfer, the uSDHC will abort the data transfer and abandon the current block. The Host Driver should read the content of the DMA System Address register to get the starting address of the abandoned data block. If the current data transfer is in multi-block mode, the uSDHC will not automatically send CMD12, even though the AC12EN bit in the Transfer Type register is set. The Host Driver sends CMD12 in this scenario and re-starts the read operation from that address. It is recommended that a Software Reset for Data be applied before the transfer is re-started.

For any write transfer mode, the uSDHC will not start data transmission until the number of words set in the RD\_WML register are in the buffer. If the buffer is full and the Host System does not read data in time, the uSDHC will stop the CLK to avoid the data buffer over-run situation.

### 10.3.4.1.3 Data Buffer and Block Size

The user needs to know the buffer size for the buffer operation during a data transfer to utilize it in the most optimized way. In the uSDHC, the only data buffer can hold up to 128 words (32-bit) and the watermark levels for write and read can be configured accordingly.

For both read and write, the watermark level can be from 1 to 128 words. For both read and write the burst length can be from 1 to 31 words. The Host Driver may configure the value according to the system situation and requirement.

During a multi-block data transfer, the block length can be set to any value between 1 and 4096 bytes, satisfying the requirements of the external card. The only restriction is from the external card, which can be limited in size or support of a partial block access (which is not the integer times of 512 bytes).

As uSDHC treats each block individually, for block sizes which are not multiples of four (not word-aligned) stuffed bytes are required at the end of each block. For example, if the block size is 7 bytes and there are 12 blocks to write, the system side must write two times for each block. For each block the ending byte will be abandoned by uSDHC because it only sends 7 bytes to the card and picks data from the following system write, resulting in 24 beats of write access in total.

### 10.3.4.1.4 Dividing Large Data Transfer

This SDIO command CMD53 definition limits the maximum data size of data transfers according to the following formula:

Max data size = Block size x Block count

The length of a multiple block transfer needs to be in block size units. If the total data length can't be divided evenly into a multiple of the block size, then there are two ways to transfer the data which depend on the function and the card design. Option 1 is for the Host Driver to split the transaction. The remainder of the block size data is then transferred by using a single block command at the end. Option 2 is to add dummy data in the last block to fill the block size. For option 2, the card must manage the removal of the dummy data.

See the figure below for an example showing the dividing of large data transfers, assuming a kind of WLAN SDIO card that only supports a block size up to 64 bytes. Although the uSDHC supports a block size of up to 4096 bytes, the SDIO can only accept a block size less than 64 bytes, so the data must be divided (see example below).

**Figure 10-40. Example for Dividing Large Data Transfers**

### 10.3.4.1.5 External DMA Request

When the internal DMA is not in use and external DMA is enabled, the Data Buffer will generate a DMA request to the system. During a write operation, when the number of WR\_WML words can be held in the buffer free space, the signal uSDHC\_dreq\_b is asserted to 0, informing the Host System of a DMA write.

The BWR bit in the Interrupt Status register is also set, as long as the BWRSEN bit in the Interrupt Status Enable register is set. The DMA request is de-asserted after several accesses to the Data Port register are made while the buffer's free space can't meet the watermark condition (free space > write watermark level).

On read operation, when the number of RD\_WML words are already in the buffer, the signal uSDHC\_dreq\_b is asserted to 0, informing the Host System for a DMA read. The BRR bit in the Interrupt Status register is also set, as long as the BRRSEN bit in the

Interrupt Status Enable register is set. The DMA request is de-asserted after several accesses to the Data Port register are made while the buffer's data can't meet the watermark condition (the number of data in buffer > read watermark level).

If the DMA burst length can't change during a data transfer for an external DMA transfer, the watermark level (read or write) must be a divisor of the block size. If it is not, transferring the block may cause buffer under-run (read operation) or over-run (write operation). For example, if the block size is 512 bytes, the watermark level of read (or write) must be a power of two between 1 and 128. For processor core polling access there is no such issue, as the last access in the block transfer can be controlled by software. The watermark level can be any value, even larger than the block size (but no greater than 128 words) because the actual number of bytes transferred by the software can be controlled and does not exceed the block size in each transfer.

The uSDHC also supports non-word aligned block size, as long as the card supports that block size. In this case, the watermark level should be set as the number of words. For example, if the block size is 31 bytes, the watermark level can be set to any number of words. For this case, the BLKSIZE bits of the Block Attribute register will be set as 1fh. For the CPU polling access, the burst length can be 1 to 128 words, without restriction. This is because the software will transfer 8 words, and the uSDHC will also set the BWR or BRR bits when the remaining data does not violate data buffer. See [DMA Burst Length](#) for more details about the dynamic watermark level of the data buffer.

For the above example, even though 8 words are transferred via the Data Port register, the uSDHC will transfer only 31 bytes over the SD Bus, as required by the BLKSIZE bits. In this data transfer, with non-word aligned block size, the endian mode should be set cautiously or invalid data will be transferred to and from the card.

### 10.3.4.2 DMA AHB Interface

The internal DMA implements a DMA engine and the AHB master. When the internal DMA is enabled, the `uSDHC_dreq_b` will not be asserted during the transfer, but the BWR and BRR bits will be set if the BWRSEN and BRRSEN bits have been set in the Interrupt Status Enable register.

See the figure below for an illustration of the DMA AHB interface block.

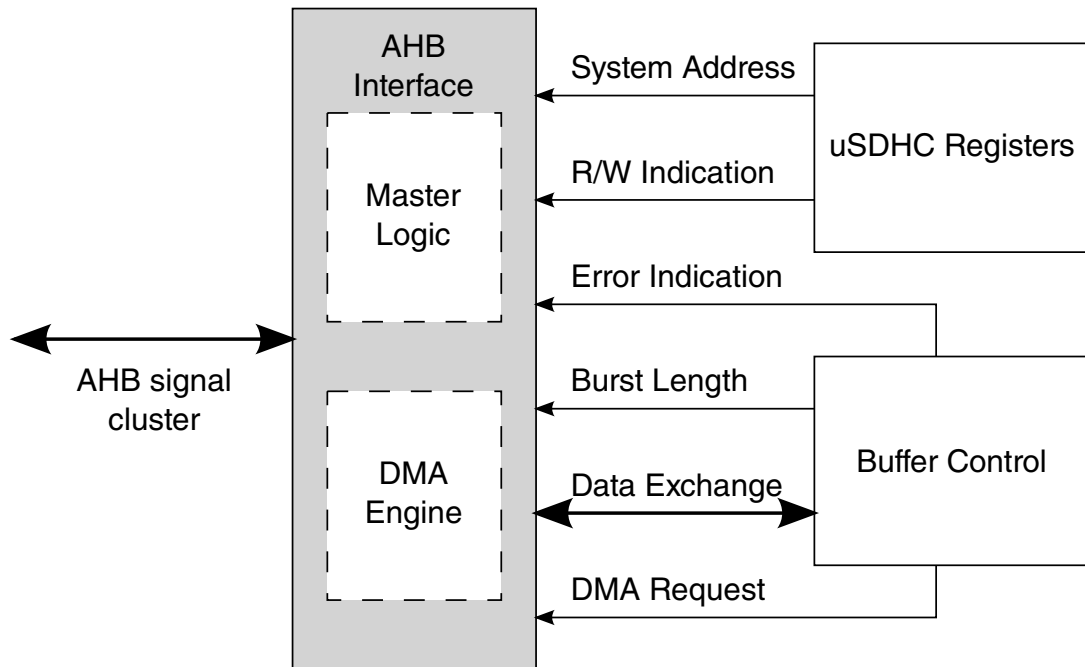

Figure 10-41. DMA AHB Interface Block

#### 10.3.4.2.1 Internal DMA Request

If the watermark level requirement is met in data transfer or if the last data of current block is ready in the data buffer, and the Internal DMA is enabled, the Data Buffer block will send a DMA request to AHB interface. Meanwhile, the external DMA request signal (`uSDHC_dreq_b`) is disabled.

The delay in response from the internal DMA engine depends on the system AHB bus loading and the priority assigned to the uSDHC. The DMA engine does not respond to the request during its burst transfer, but is ready to serve as soon as the burst is over. The Data Buffer de-asserts the request if the data buffer space (for write) or bytes in data buffer is smaller than the watermark level. Upon access to the buffer by internal DMA, the Data Buffer updates its internal buffer pointer, and when the watermark level is satisfied or the last data of current block is ready in the data buffer, another DMA request is sent.

The data transfer is in the block unit, and the subsequent watermark level is always set as the remaining number of words. For instance, for a multi block data read with each block size of 31 bytes, and the burst length set to 6 words. After the first burst transfer, if there are more than 2 words in the buffer (which might contain some data of the next block), another DMA request is sent. This is because the remaining number of words to send for the current block is  $(31 - 6 * 4) / 4 = 2$ . The uSDHC will read 2 words out of the buffer, with 7 valid bytes and 1 stuffed byte.

#### 10.3.4.2.2 DMA Burst Length

Just like a CPU polling access, the DMA burst length for the internal DMA engine can be from 1 to 16 words. The actual burst length for the DMA depends on the lesser of the configured burst length or the remaining words of the current block.

See the example in [Internal DMA Request](#). After 6 words are read, the burst length will be 2 words, then the next burst length will be 6 words. This is because the next block starts, which is 31 bytes, more than 6 words. The Host Driver may take this variable burst length into account. It is also acceptable to configure the burst length as the divisor of the block size, so that each time the burst length will be the same.

#### 10.3.4.2.3 AHB Master Interface

It is possible that the internal AHB DMA engine could fail during the data transfer. Upon detection of an AHB bus error during DMA transfer, the DMA engine stops the transfer and goes to the idle state. At that point, the internal data buffer stops receiving incoming data and sending out data. The DMAE bit in the Interrupt Status register will be generated to host CPU to report a bus error condition.

Once the DMAE interrupt is received, the software shall send a CMD12 to abort the current transfer and read the DS\_ADDR bits of the DMA System Address register to get the starting address of the corrupted block. After the DMA error is fixed, the software should apply a data reset and re-start the transfer from this address to recover the corrupted block. DMA operation will resume when the interrupt is serviced by software.

#### 10.3.4.2.4 ADMA Engine

In the SD Host Controller Standard, a new DMA transfer algorithm called the ADMA (Advanced DMA) is defined. For Simple DMA, once the page boundary is reached, a DMA interrupt will be generated and the new system address shall be programmed by the Host Driver.

The ADMA defines the programmable descriptor table in the system memory. The Host Driver can calculate the system address at the page boundary and program the descriptor table before executing ADMA. It reduces the frequency of interrupts to the host system. Therefore, higher speed DMA transfers could be realized since the Host MCU intervention would not be needed during long DMA based data transfers.

There are two types of ADMA: ADMA1 and ADMA2 in Host Controller. ADMA1 can support data transfer of 4KB aligned data in system memory. ADMA2 improves the restriction so that data of any location and any size can be transferred in system memory. Their formats of Descriptor Table are different.

ADMA can recognize all kinds of descriptors define in SD Host Controller Standard, and if 'End' flag is detected in the descriptor, ADMA will stop after this descriptor is processed.

#### 10.3.4.2.4.1 ADMA Concept and Descriptor Format

For ADMA1, including the following descriptors:

- Valid/Invalid descriptor.
- Nop descriptor.
- Set data length descriptor.
- Set data address descriptor.
- Link descriptor.
- Interrupt flag and End flag in descriptor.

For ADMA2, including the following descriptors:

- Valid/Invalid descriptor.
- Nop descriptor.
- Rsv descriptor.
- Set data length & address descriptor.
- Link descriptor.
- Interrupt flag and End flag in descriptor.

See [Figure 10-42](#) for the format of the descriptor table for ADMA1.

[Figure 10-45](#) explains the ADMA2 format. ADMA2 deals with the lower 32-bit first, and then the higher 32-bit. If the 'Valid' flag of descriptor is 0, it will ignore the high 32-bit. Address field shall be set on word aligned(lower 2-bit is always set to 0). Data length is in byte unit.

ADMA will start read/write operation after it reaches the Tran state, using the data length and data address analyzed from most recent descriptor(s).

For ADMA1, the valid data length descriptor is the last Set type descriptor before Tran type descriptor. Every Tran type will trigger a transfer, and the transfer data length is extracted from the most recent Set type descriptor. If there is no Set type descriptor after the previous Trans descriptor, the data length will be the value for previous transfer, or 0 if no Set descriptor is ever met.

For ADMA2, Tran type descriptor contains both data length and transfer data address, so only a Tran type descriptor can start a data transfer

Address/ Page Field		Address/ Page Field		Attribute Field					
31	12	11	6	5	4	3	2	1	0
Address or Data Length		000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	31- 28	27- 12
0	0	Nop	No Operation	Don't Care	
0	1	Set	Set Data Length	0000	Data Length
1	0	Tran	Transfer Data	Data Address	
1	1	Link	Link Descriptor	Descriptor Address	

Valid	Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is processed.

**Figure 10-42. Format of the ADMA1 Descriptor Table**

System Address Register points to the head node of Descriptor Table

**Figure 10-43. Concept and Access Method of ADMA1 Descriptor Table**

## Ultra Secured Digital Host Controller (uSDHC)

Address Field		Length		Reserved		Attribute Field					
63	32	31	16	15	06	05	04	03	02	01	00
32-bit Address		16-bit length		0000000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	Operation
0	0	Nop	No Operation	Don't Care
0	1	Rsv	Reserved	Same as Nop. Read this line and go to next one
1	0	Tran	Transfer Data	Transfer data with address and length set in this descriptor line
1	1	Link	Link Descriptor	Link to another descriptor

Valid	Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is processed.

**Figure 10-44. Format of the ADMA2 Descriptor Table**

**Figure 10-45. Concept and Access Method of ADMA2 Descriptor Table**

#### 10.3.4.2.4.2 ADMA Interrupt

If the interrupt flag descriptor is set, ADMA will generate an interrupt according to various types of descriptors:

For ADMA1:

- Set type of descriptor: interrupt is generated when data length is set.
- Tran type descriptor: interrupt is generated when this transfer is complete.
- Link type of descriptor: interrupt is generated when new descriptor address is set.
- Nop type of descriptor: interrupt is generated just after this descriptor is fetched.

For ADMA2:

- Tran type of descriptor: interrupt is generated when this transfer is complete.
- Link type of descriptor: interrupt is generated when new descriptor address is set.
- Nop/Rsv type of descriptor: interrupt is generated just after this descriptor is fetched.

### 10.3.4.2.4.3 ADMA Error

The ADMA will stop whenever any error is encountered. These errors include:

- Fetching descriptor error
- AHB response error
- Data length mismatch error

An ADMA descriptor error will be generated when it fails to detect a 'Valid' flag in the descriptor. If an ADMA descriptor error occurs, the interrupt is not generated even if the 'Interrupt' flag of this descriptor is set.

When BLKCNTEN bit is set, data length set in buffer must be equal to the whole data length set in descriptor nodes, otherwise data length mismatch error will be generated.

When BLKCNTEN bit is not set, then whole data length set in descriptor should be a multiple of block lengths; otherwise, when data set in the descriptor nodes are not performed at block boundaries, then data mismatch errors will occur.

### 10.3.4.3 Register Bank with IP Bus Interface

Register accesses via the IP Bus interface are actually on the Register Bank.

See [Figure 10-46](#) below for the block diagram.

**Figure 10-46. Register Bank Diagram**

Only 32-bit access is allowed, and no partial read / write is supported, thus all accesses are word aligned.

### 10.3.4.3.1 SD Protocol Unit

The SD protocol unit deals with all SD protocol affairs.

The SD Protocol Unit performs the following functions:

- Acts as the bridge between the internal buffer and the SD bus
- Sends the command data as well as its argument serially
- Stores the serial response bit stream into corresponding registers
- Detects the bus state on the CMD/DAT lines
- Monitors the interrupt from the SDIO card
- Asserts the read wait signal
- Gates off the SD clock when buffer is announcing danger status
- Detects the write protect state

The SD Protocol Unit consists of four sub modules:

1. SD control misc.
2. Command control.

- 3. Data control.
- 4. Clock control

### 10.3.4.3.2 SD control misc

In the SD control misc unit, the card detect(include the CD\_B and DATA3 used as Card Detection), write protection and card interrupt are implemented.

This module monitors the signal level on all 8 data lines, the command lines, and directly routes the level values into the Register Bank. The driver can use this for debug purposes.

The module also detects the WP (Write Protect) line. If WP is active, writes to the register bank will be ignored.

This module also drives the LCTL output signal when the LCTL bit is set by the driver.

### 10.3.4.3.3 SD Clock control

If the internal data buffer is near full(for read) or near empty(for write), the SD clock must be gated off to avoid buffer over/under-run, this module will assert the gate of the output SD clock to shut the clock off. After the buffer has space(for read) or has data(for write), the clock gate of this module will open and the SD clock will be active again.

### 10.3.4.3.4 Command control

The Command Control module deals with the transactions on the CMD line.

See the figure below for an illustration of the structure for the Command CRC Shift Register.

**Figure 10-47. Command CRC Shift Register**

The CRC polynomials for the CMD are as follows:

Generator polynomial:  $G(x) = x^7 + x^3 + 1$   
 $M(x) = (\text{first bit}) * x^n + (\text{second bit}) * x^{n-1} + \dots + (\text{last bit}) * x^0$   
 $\text{CRC}[6:0] = \text{Remainder} [(M(x) * x^7) / G(x)]$

### 10.3.4.3.5 Data control

The Data Agent deals with the transactions on the eight data lines. Moreover, this module also detects the busy state on the DATA0 line, and generates the Read Wait state by the request from the Transceiver.

The CRC polynomials for the DATA are as follows:

Generator polynomial:  $G(x) = x^{16} + x^{12} + x^5 + 1$   
 $M(x) = (\text{first bit}) * x^n + (\text{second bit}) * x^{n-1} + \dots + (\text{last bit}) * x^0$   
 $\text{CRC}[15:0] = \text{Remainder} [(M(x) * x^{16}) / G(x)]$

### 10.3.4.4 Clock & Reset Manager

This module controls all the reset signals within the uSDHC.

There are four kinds of reset signals within uSDHC:

1. Hardware reset.
2. Software reset for all logic.
3. Software reset for the data logic.
4. Software reset for the command logic.

All these signals are fed into this module and stable signals are generated inside the module to reset all other modules. The module also gates off all the inside signals.

### 10.3.4.5 Clock Generator

The Clock Generator generates the card CLK by peripheral source clock in two stages.

Refer to the figure below for the structure of the divider. The term "Base" represents the frequency of peripheral source clock.

**Figure 10-48. Two Stages of the Clock Divider**

The first stage outputs an intermediate clock (DIV), which can be Base, Base/2, Base/3, ..., or Base/16.

The second stage is a prescaler, and outputs the actual internal working clock (`card_clk`). This clock is the driving clock for all sub modules of the SD Protocol Unit, and the sync FIFOs (see [Figure 10-37](#)) to synchronize with the data rate from the internal data buffer. The frequency of the clock output from this stage, can be  $DIV$ ,  $DIV/2$ ,  $DIV/4$ ,..., or  $DIV/256$ . Thus the highest frequency of the `card_clk` is Base, and the next highest is  $Base/2$ , while the lowest frequency is  $Base/4096$ . If the duty cycle of Base clock is 50%, the duty cycle of `card_clk` is also 50%, even when the compound divisor is an odd value.

Please note, in SDR mode and DDR mode, the CLK are different.

- In SDR mode, CLK is equal to the internal working clock(`card_clk`).
- In DDR mode, CLK is equal to the `card_clk/2`.

### 10.3.4.6 SDIO Card Interrupt

Information on Interrupts in 1-bit Mode, Interrupts in 4-bit Mode, and Card Interrupt Handling are detailed in the sections below.

#### 10.3.4.6.1 Interrupts in 1-bit Mode

In this case the `DATA1` pin is dedicated to providing the interrupt function. An interrupt is asserted by pulling the `DATA1` low from the SDIO card, until the interrupt service is finished to clear the interrupt.

#### 10.3.4.6.2 Interrupt in 4-bit Mode

Since the interrupt and data line 1 share Pin 8 in 4-bit mode, an interrupt will only be sent by the card and recognized by the host during a specific time. This is known as the Interrupt Period. The uSDHC will only sample the level on Pin 8 during the Interrupt Period. At all other times, the host will ignore the level on Pin 8, and treat it as the data signal. The definition of the Interrupt Period is different for operations with single block and multiple block data transfers.

In the case of normal single data block transmissions, the Interrupt Period becomes active two clock cycles after the completion of a data packet. This Interrupt Period lasts until after the card receives the end bit of the next command that has a data block transfer associated with it.

For multiple block data transfers in 4-bit mode, there is only a limited period of time that the Interrupt Period can be active due to the limited period of data line availability between the multiple blocks of data. This requires a more strict definition of the Interrupt Period. For this case, the Interrupt Period is limited to two clock cycles. This begins two

clocks after the end bit of the previous data block. During this 2-clock cycle interrupt period, if an interrupt is pending, the DATA1 line will be held low for one clock cycle with the last clock cycle pulling DATA1 high. On completion of the Interrupt Period, the card releases the DATA1 line into the high Z state. The uSDHC samples the DATA1 during the Interrupt Period when the IABG bit in the Protocol Control register is set.

Refer to SDIO Card Specification v1.10f for further information about the SDIO card interrupt.

### 10.3.4.6.3 Card Interrupt Handling

When the CINTIEN bit in the Interrupt Signal Enable Register is set to 0, the uSDHC clears the interrupt request to the Host System. The Host Driver should clear this bit before servicing the SDIO Interrupt and should set this bit again after all interrupt requests from the card are cleared to prevent inadvertent interrupts.

The SDIO Card Interrupt Status can be cleared by writing 1 to this bit. But as the interrupt source from the SDIO card does not clear, this bit is set again. In order to clear this bit, it is required to reset the interrupt source from the external card followed by a writing 1 to this bit. In 1-bit mode, the uSDHC will detect the SDIO Interrupt with or without the SD clock (to support wakeup). In 4-bit mode, the interrupt signal is sampled during the Interrupt Period, so there are some sample delays between the interrupt signal from the SDIO card and the interrupt to the Host System Interrupt Controller. When the SDIO status has been set, and the Host Driver needs to service this interrupt, so the SDIO bit in the Interrupt Control Register of SDIO card will be cleared. This is required to clear the SDIO interrupt status latched in the uSDHC and to stop driving the interrupt signal to the System Interrupt Controller. The Host Driver must issue a CMD52 to clear the card interrupt. After completion of the card interrupt service, the SDIO Interrupt Status Enable bit is set to 1, and the uSDHC starts sampling the interrupt signal again.

See the figure below for an illustration of the SDIO card interrupt scheme and for the sequences of software and hardware events that take place during a card interrupt handling procedure.

**Figure 10-49. Card Interrupt Scheme and Card Interrupt Detection and Handling Procedure**

### 10.3.4.7 Card Insertion and Removal Detection

The uSDHC uses either the DATA3 pin or the CD\_B pin to detect card insertion or removal. When there is no card on the MMC/SD bus, the DATA3 will be pulled to a low voltage level by default.

When any card is inserted to or removed from the socket, the uSDHC detects the logic value changes on the DATA3 pin and generates an interrupt. When the DATA3 pin is not used for card detection (for example, it is implemented in GPIO), the CD\_B pin must be connected for card detection. Whether DATA3 is configured for card detection or not, the CD\_B pin is always a reference for card detection. Whether the DATA3 pin or the CD\_B pin is used to detect card insertion, the uSDHC will send an interrupt (if enabled) to inform the Host system that a card is inserted.

### 10.3.4.8 Power Management and Wake Up Events

When there is no operation between the uSDHC and the card through the SD bus, the user can completely disable the `ipg_clk` and `ipg_perclk` in the chip level clock control module to save power. When the user needs to use the uSDHC to communicate with the card, it can enable the clock and start the operation.

In some circumstances, when the clocks to the uSDHC are disabled, for instance, when the system is in low power mode, there are some events for which the user needs to enable the clock and handle the event. These events are called wakeup interrupts. The uSDHC can generate these interrupt even when there are no clocks enabled. The three interrupts which can be used as wake up events are:

1. Card Removal Interrupt
2. Card Insertion Interrupt
3. Interrupt from SDIO card

The uSDHC offers a power management feature. By clearing the clock enabled bits in the System Control Register, the clocks are gated in the low position to the uSDHC. For maximum power saving, the user can disable all the clocks to the uSDHC when there is no operation in progress.

These three wake up events (or wakeup interrupts) can also be used to wake up the system from low-power modes.

#### NOTE

To make the interrupt a wakeup event, when all the clocks to the uSDHC are disabled or when the whole system is in low power mode, the corresponding wakeup enabled bit needs to be set. Refer to [Protocol Control \(uSDHC\\_PROT\\_CTRL\)](#) for more information on the uSDHC Protocol Control register.

#### 10.3.4.8.1 Setting Wake Up Events

For the uSDHC to respond to a wakeup event, the software must set the respective wakeup enable bit before the CPU enters sleep mode.

Before the software disables the host clock, it should ensure that all of the following conditions have been met:

- No Read or Write Transfer is active
- Data and Command lines are not active
- No interrupts are pending
- Internal data buffer is empty

### 10.3.4.9 MMC fast boot

The Embedded MultiMediaCard (eMMC4.3) specification adds a fast boot feature which requires hardware support. There are two types of fast boot mode, boot operation, and alternative boot operation in the eMMC4.3 specification. Each type also has with-acknowledge and without-acknowledge modes.

In boot operation mode, the master (MultiMediaCard host) can read boot data from the slave (MMC device) by keeping CMD line low after power-on, or sending CMD0 with argument + 0xFFFFFFFF (optional for slave), before issuing CMD1.

#### NOTE

For the eMMC4.3 card setting, please see the eMMC4.3 specification.

#### 10.3.4.9.1 Boot operation

#### NOTE

For the purposes of this documentation, fast boot is called "normal fast boot mode".

If the CMD line is held LOW for 74 clock cycles and more after power-up before the first command is issued, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within 1 second after the CMD line goes LOW, the slave starts to send the first boot data to the master on the DATA line(s). The master must keep the CMD line LOW to read all of the boot data.

If boot acknowledge is enabled, the slave has to send acknowledge pattern '010' to the master within 50ms after the CMD line goes LOW. If boot acknowledge is disabled, the slave will not send out acknowledge pattern '010'.

The master can terminate boot mode with the CMD line HIGH.

Boot operation will be terminated when all contents of the enabled boot data are sent to the master. After boot operation is executed, the slave shall be ready for CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.

**Figure 10-50. MultiMediaCard state diagram (normal boot mode)**

### 10.3.4.9.2 Alternative boot operation

This boot function is optional for the device. If bit 0 in the extended CSD byte[228] is set to '1', the device supports the alternative boot operation.

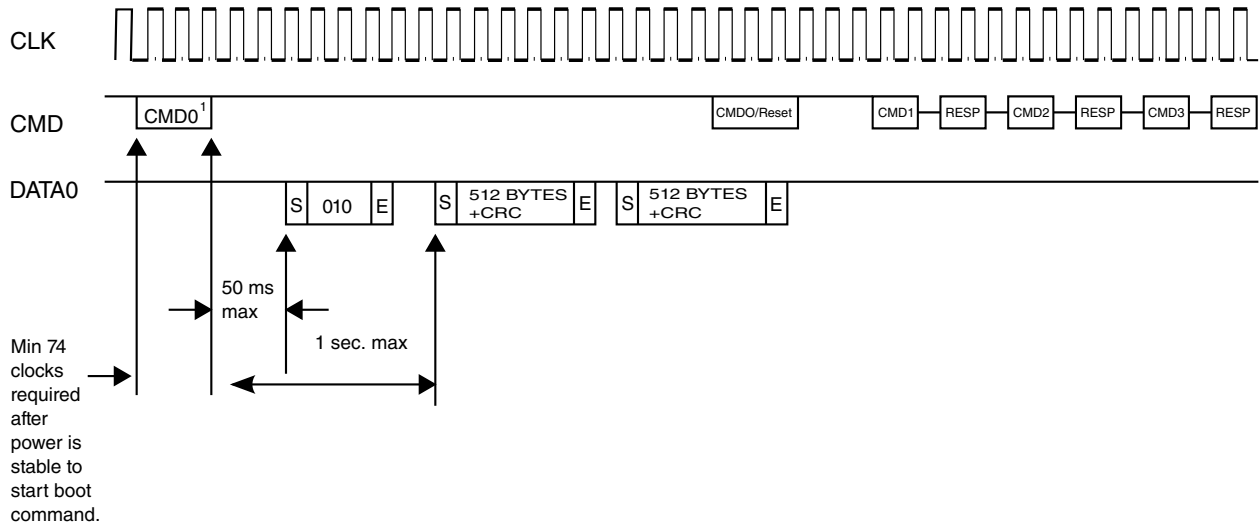

After power-up, if the host issues CMD0 with the argument of 0xFFFFFFFFFA after 74 clock cycles, before CMD1 is issued or the CMD line goes low, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within 1 second after CMD0 with the argument of 0xFFFFFFFFFA is issued, the slave starts to send the first boot data to the master on the DATA line(s).

If boot acknowledge is enabled, the slave has to send the acknowledge pattern '010' to the master within 50ms after the CMD0 with the argument of 0xFFFFFFFFFA is received. If boot acknowledge is disabled, the slave will not send out acknowledge pattern '010'.

The master can terminate boot mode by issuing CMD0 (Reset).

Boot operation will be terminated when all contents of the enabled boot data are sent to the master. After boot operation is executed, the slave shall be ready for CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.

NOTE 1. CMD0 with argument 0xFFFFFFFF

Figure 10-51. MultiMediaCard state diagram (alternative boot mode)

### 10.3.5 Initialization/Application of uSDHC

All communication between the system and cards are controlled by the host. The host sends commands of two types: broadcast and addressed (point-to-point).

Broadcast commands are intended for all cards, such as GO\_IDLE\_STATE, SEND\_OP\_COND, ALL\_SEND\_CID. In Broadcast mode, all cards are in the open-drain mode to avoid bus contention. Refer to [Commands for MMC/SD/SDIO](#) for the commands of bc and bcr categories.

After the Broadcast command CMD3 is issued, the cards enter standby mode. Addressed type commands are used from this point. In this mode, the CMD/DATA I/O pads will turn to push-pull mode, to have the driving capability for maximum frequency operation. Refer to [Commands for MMC/SD/SDIO](#) for the commands of ac and adtc categories.

#### 10.3.5.1 Command Send & Response Receive Basic Operation

Assuming the data type WORD is an unsigned 32-bit integer, the below flow is a guideline for sending a command to the card(s):

```

send_command(cmd_index, cmd_arg, other requirements)
{
WORD wCmd; // 32-bit integer to make up the data to write into Transfer Type register, it is
recommended to implement in a bit-field manner
wCmd = (<cmd_index> & 0x3f) >> 24; // set the first 8 bits as '00'+<cmd_index>
set CMDTYP, DPSEL, C1CEN, CCCEN, RSTYP, DTDSEL accorind to the command index;
if (internal DMA is used) wCmd |= 0x1;
if (multi-block transfer) {
    set MSBSEL bit;
    if (finite block number) {
        set BCEN bit;
        if (auto12 command is to use) set AC12EN bit;
    }
}
write_reg(CMDARG, <cmd_arg>); // configure the command argument
write_reg(XFERTYP, wCmd); // set Transfer Type register as wCmd value to issue the command
}
wait_for_response(cmd_index)
{
while (CC bit in IRQ Status register is not set); // wait until Command Complete bit is set
read IRQ Status register and check if any error bits about Command are set
if (any error bits are set) report error;
write 1 to clear CC bit and all Command Error bits;
}

```

For the sake of simplicity, the function `wait_for_response` is implemented here by means of polling. For an effective and formal way, the response is usually checked after the Command Complete Interrupt is received. When doing this, make sure the corresponding interrupt status bits are enabled.

For some scenarios, the response time-out is expected. For instance, after all cards respond to CMD3 and go to the Standby State, no response to the Host when CMD2 is sent. The Host Driver will deal with "fake" errors like this with caution.

### 10.3.5.2 Card Identification Mode

When a card is inserted to the socket or the card was reset by the host, the host needs to validate the operation voltage range, identify the cards, request the cards to publish the Relative Card Address (RCA) or to set the RCA for the MMC cards.

#### 10.3.5.2.1 Card Detect

See the figure below for a flow diagram showing the detection of MMC, SD and SDIO cards using the uSDHC.

**Figure 10-52. Flow Diagram for Card Detection**

Here is the card detect sequence:

- Set the CINSIEN bit to enable card detection interrupt
- When an interrupt from the uSDHC is received, check the CINS bit in the Interrupt Status register to see if it was caused by card insertion
- Clear the CINSIEN bit to disable the card detection interrupt and ignore all card insertion interrupts afterwards

### 10.3.5.2.2 Reset

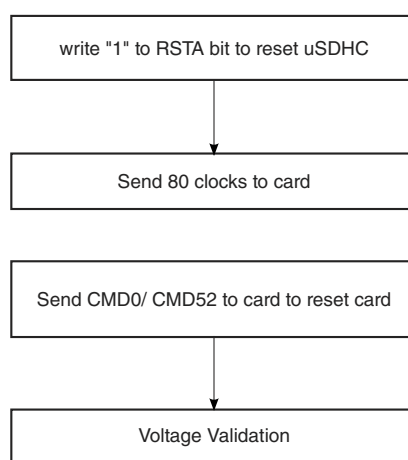

The host consists of three types of resets:

- Hardware reset (Card and Host) which is driven by POR (Power On Reset)

- Software reset (Host Only) is initiated by the write operation on the RSTD, RSTC, or RSTA bits of the System Control register to reset the data part, command part, or all parts of the Host Controller, respectively
- Card reset (Card Only). The command, "Go\_Idle\_State" (CMD0), is the software reset command for all types of MMC cards, SD Memory cards. This command sets each card into the Idle State regardless of the current card state. For an SD I/O Card, CMD52 is used to write an I/O reset in the CCCR. The cards are initialized with a default relative card address (RCA=0x0000) and with a default driver stage register setting (lowest speed, highest driving current capability).

After the card is reset, the host needs to validate the voltage range of the card. See the figure below for the software flow to reset both the uSDHC and the card.

**Figure 10-53. Flow Chart for Reset of the uSDHC and SD I/O Card**

```

software_reset()
{
set_bit(SYSCTRL, RSTA); // software reset the Host
set_DTOCV and SDCLKFS bit fields to get the CLK of frequency around 400kHz
configure IO pad to set the power voltage of external card to around 3.0V
poll bits CIHB and CDIHB bits of PRSSTAT to wait both bits are cleared
set_bit(SYSCTRL, INTIA); // send 80 clock ticks for card to power up
send_command(CMD_GO_IDLE_STATE, <other parameters>); // reset the card with CMD0
or send_command(CMD_IO_RW_DIRECT, <other parameters>);
}
  
```

### 10.3.5.2.3 Voltage Validation

All cards should be able to establish communication with the host using any operation voltage in the maximum allowed voltage range specified in the card specification. However, the supported minimum and maximum values for V<sub>dd</sub> are defined in the Operation Conditions Register (OCR) and may not cover the whole range.

Cards that store the CID and CSD data in the preload memory are only able to communicate this information under data transfer Vdd conditions. This means if the host and card have non-common Vdd ranges, the card will not be able to complete the identification cycle, nor will it be able to send CSD data.

Therefore, a special command Send\_Op\_Cont (CMD1 for MMC), SD\_Send\_Op\_Cont (ACMD41 for SD Memory) and IO\_Send\_Op\_Cont (CMD5 for SD I/O) is used. The voltage validation procedure is designed to provide a mechanism to identify and reject cards which do not match the Vdd range(s) desired by the host. This is accomplished by the host sending the desired Vdd voltage window as the operand of this command. Cards that can't perform the data transfer in the specified range must discard themselves from further bus operations and go into the Inactive State. By omitting the voltage range in the command, the host can query each card and determine the common voltage range before sending out-of-range cards into the Inactive State. This query should be used if the host is able to select a common voltage range or if a notification shall be sent to the system when a non-usable card in the stack is detected.

The following steps show how to perform voltage validation when a card is inserted:

```

voltage_validation(voltage_range_argument)
{
label the card as UNKNOWN;
send_command(IO_SEND_OP_COND, 0x0, <other parameters are omitted>); // CMD5, check SDIO
operation voltage, command argument is zero
if (RESP_TIMEOUT != wait_for_response(IO_SEND_OP_COND)) { // SDIO command is accepted
    if (0 < number of IO functions) {
        label the card as SDIO;
        IORDY = 0;
        while (!(IORDY in IO OCR response)) { // set voltage range for each IO
function
            send_command(IO_SEND_OP_COND, <voltage range>, <other
parameter>);
            wait_for_response(IO_SEND_OP_COND);
        } // end of while ...
    } // end of if (0 < ...
    if (memory part is present inside SDIO card) Label the card as SDCombo; // this is
an
SD-Combo card
} // end of if (RESP_TIMEOUT ...
if (the card is labelled as SDIO card) return; // card type is identified and voltage range
is
set, so exit the function;
send_command(APP_CMD, 0x0, <other parameters are omitted>); // CMD55, Application specific
CMD
prefix
if (no error calling wait_for_response(APP_CMD, <...>) { // CMD55 is accepted
    send_command(SD_APP_OP_COND, <voltage range>, <...>); // ACMD41, to set voltage
range
for memory part or SD card
    wait_for_response(SD_APP_OP_COND); // voltage range is set
    if (Card type is UNKNOWN) label the card as SD;
    return; //
} // end of if (no error ...
else if (errors other than time-out occur) { // command/response pair is corrupted
    deal with it by program specific manner;
} // of else if (response time-out
else { // CMD55 is refuse, it must be MMC card if (card is already labelled as SDCombo)
{ //
change label

```

```

        re-label the card as SDIO;
        ignore the error or report it;
        return; // card is identified as SDIO card
    } // of if (card is ...
    send_command(SEND_OP_COND, <voltage range>, <...>);
    if (RESP_TIMEOUT == wait_for_response(SEND_OP_COND)) { // CMD1 is not accepted,
either
        label the card as UNKNOWN;
        return;
    } // of if (RESP_TIMEOUT ...
} // of else
}

```

### 10.3.5.2.4 Card Registry

Card registry for the MMC and SD/SDIO/SD Combo cards are different. For the SD Card, the Identification process starts at a clock rate lower than 400 kHz and the power voltage higher than 2.7 V (as defined by the Card spec). At this time, the CMD line output drives are push-pull drivers instead of open-drain. After the bus is activated, the host will request the card to send their valid operation conditions.

The response to ACMD41 is the operation condition register of the card. The same command shall be send to all of the new cards in the system. Incompatible cards are put into the Inactive State. The host then issues the command, All\_Send\_CID (CMD2), to each card to get its unique card identification (CID) number. Cards that are currently unidentified (in the Ready State), send their CID number as the response. After the CID is sent by the card, the card goes into the Identification State.

The host then issues Send\_Relative\_Addr (CMD3), requesting the card to publish a new relative card address (RCA) that is shorter than the CID. This RCA will be used to address the card for future data transfer operations. Once the RCA is received, the card changes its state to the Standby State. At this point, if the host wants the card to have an alternative RCA number, it may ask the card to publish a new number by sending another Send\_Relative\_Addr command to the card. The last published RCA is the actual RCA of the card.

The host repeats the identification process with CMD2 and CMD3 for each card in the system until the last CMD2 gets no response from any of the cards in system.

For MMC operation, the host starts the card identification process in open-drain mode with the identification clock rate lower than 400 kHz and the power voltage higher than 2.7 V. The open drain driver stages on the CMD line allow parallel card operation during card identification. After the bus is activated the host will request the cards to send their valid operation conditions (CMD1). The response to CMD1 is the "wired OR" operation on the condition restrictions of all cards in the system. Incompatible cards are sent into the Inactive State. The host then issues the broadcast command All\_Send\_CID (CMD2), asking all cards for their unique card identification (CID) number. All unidentified cards (the cards in Ready State) simultaneously start sending their CID numbers serially, while

bit-wise monitoring their outgoing bit stream. Those cards, whose outgoing CID bits do not match the corresponding bits on the command line in any one of the bit periods, stop sending their CID immediately and must wait for the next identification cycle. Since the CID is unique for each card, only one card can be successfully send its full CID to the host. This card then goes into the Identification State. Thereafter, the host issues Set\_Relative\_Addr (CMD3) to assign to the card a relative card address (RCA). Once the RCA is received the card state changes to the Stand-by State, and the card does not react in further identification cycles, and its output driver switches from open-drain to push-pull. The host repeats the process, mainly CMD2 and CMD3, until the host receives a time-out condition to recognize the completion of the identification process.

For operation as MMC cards:

```

card_registry()
{
do { // decide RCA for each card until response time-out
    if(card is labelled as SDCombo or SDIO) { // for SDIO card like device
        send_command(SET_RELATIVE_ADDR, 0x00, <...>); // ask SDIO card to
publish its
RCA
        retrieve RCA from response;
    } // end if (card is labelled as SDCombo ...
    else if (card is labelled as SD) { // for SD card
        send_command(ALL_SEND_CID, <...>);
        if (RESP_TIMEOUT == wait_for_response(ALL_SEND_CID)) break;
        send_command(SET_RELATIVE_ADDR, <...>);
        retrieve RCA from response;
    } // else if (card is labelled as SD ...
    else if (card is labelled as MMC) {
        send_command(ALL_SEND_CID, <...>);
        rca = 0x1; // arbitrarily set RCA, 1 here for example
        send_command(SET_RELATIVE_ADDR, 0x1 << 16, <...>); // send RCA at upper
16
bits
        } // end of else if (card is labelled as MMC ...
    } while (response is not time-out);
}

```

### 10.3.5.3 Card Access

Information about Block Write, Block Read, Suspend Resume, ADMA Usage, Transfer Error, and Card Interrupt are detailed in the sections below.

#### 10.3.5.3.1 Block Write

Information on Normal Write, DDR Write, and Write with Pause are detailed in the sections below.

### 10.3.5.3.1.1 Normal Write

During a block write (CMD24 - 27, CMD60, CMD61), one or more blocks of data are transferred from the host to the card with a CRC appended to the end of each block by the host. If the CRC fails, the card shall indicate the failure on the DATA line. The transferred data will be discarded and not written, and all further transmitted blocks (in multiple block write mode) will be ignored.

If the host uses partial blocks whose accumulated length is not block aligned and block misalignment is not allowed (CSD parameter WRITE\_BLK\_MISALIGN is not set), the card detects the block misalignment error and aborts the programming before the beginning of the first misaligned block. The card sets the ADDRESS\_ERROR error bit in the status register, and while ignoring all further data transfer, waits in the Receive-data-State for a stop command. The write operation is also aborted if the host tries to write over a write protected area.

For MMC and SD cards, programming of the CID and CSD registers does not require a previous block length setting. The transferred data is also CRC protected. If a part of the CSD or CID register is stored in ROM, then this unchangeable part must match the corresponding part of the receive buffer. If this match fails, then the card will report an error and not change any register contents.

For all types of cards, some may require long and unpredictable periods of time to write a block of data. After receiving a block of data and completing the CRC check, the card will begin writing and hold the DATA line low if its write buffer is full and unable to accept new data from a new WRITE\_BLOCK command. The host may poll the status of the card with a SEND\_STATUS command (CMD13) or other means for SDIO cards at any time, and the card will respond with its status. The responded status indicates whether the card can accept new data or whether the write process is still in progress. The host may deselect the card by issuing a CMD7 (to select a different card) to place the card into the Standby State and release the DATA line without interrupting the write operation. When re-selecting the card, it will reactivate the busy indication by pulling DATA to low if the programming is still in progress and the write buffer is unavailable.

The software flow to write to a card incorporates the internal DMA and the write operation is a multi-block write with the Auto CMD12 enabled. For the other two methods (by means of external DMA or CPU polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to write to a card is described below:

1. Check the card status, wait until the card is ready for data.
2. Set the card block length/size:

- For SD/MMC cards, use SET\_BLOCKLEN (CMD16)
  - For SDIO cards or the I/O portion of SDCombo cards, use IO\_RW\_DIRECT (CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the uSDHC block length register to be the same as the block length set for the card in Step 2.
  4. Set the uSDHC number block register (NOB), nob is 5 (for instance).
  5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
  6. Wait for the Transfer Complete interrupt.
  7. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

#### 10.3.5.3.1.2 DDR Write

uSDHC supports dual data rate mode.

The software flow to write to a card in ddr mode is described as below:

1. Check the card status, wait until the card is ready for data.
2. For eMMC4.4 card, block length only can be set to 512byte.
3. Set the uSDHC number block register (NOB), nob is 5 (for instance).
4. Set eMMC4.4 card to high speed mode, use SWITCH(CMD6).
5. Set eMMC4.4 card bus with (4-bit /8-bit ddr mode), use SWITCH(CMD6).
6. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The DDR\_EN bit should be set. The AC12EN bit should also be set.
7. Wait for the Transfer Complete interrupt.
8. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

#### 10.3.5.3.1.3 Write with Pause

The write operation can be paused during the transfer. Instead of stopping the CLK at any time to pause all the operations, which is also inaccessible to the Host Driver, the Driver can set the Stop At Block Gap Request(SABGREQ) bit in the Protocol Control register to pause the transfer between the data blocks. As there is no time-out condition in a write operation during the data blocks, a write to all types of cards can be paused in this way, and if the DATA0 line is not required to de-assert to release the busy state, no suspend command is needed.

Like in the flow described in [Normal Write](#), the write with pause is shown with the same kind of write operation:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
  - For SD/MMC, use SET\_BLOCKLEN (CMD16)
  - For SDIO cards or the I/O portion of SDCombo cards, use IO\_RW\_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the uSDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the uSDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Set the SABGREQ bit.
7. Wait for the Transfer Complete interrupt.
8. Clear the SABGREQ bit.
9. Check the status bit to see if a write CRC error occurred.
10. Set the CREQ bit to continue the write operation.
11. Wait for the Transfer Complete interrupt.
12. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

The number of blocks left during the data transfer is accessible by reading the contents of the BLKCNT field in the Block Attribute register. As the data transfer and the setting of the SABGREQ bit are concurrent, and the delay of register read and the register setting, the actual number of blocks left may not be exactly the value read earlier. The Driver shall read the value of BLKCNT after the transfer is paused and the Transfer Complete interrupt is received.

It is also possible the last block has begun when the Stop At Block Gap Request is sent to the buffer. In this case, the next block gap is actually the end of the transfer. These types of requests are ignored and the Driver should treat this as a non-pause transfer and deal with it as a common write operation.

When the write operation is paused, the data transfer inside the Host System is not stopped, and the transfer is active until the data buffer is full. Because of this (if not needed), it is recommended to avoid using the Suspend Command for the SDIO card. This is because when such a command is sent, the uSDHC thinks the System will switch to another function on the SDIO card, and flush the data buffer. The uSDHC takes the Resume Command as a normal command with data transfer, and it is left for the Driver to set all the relevant registers before the transfer is resumed. If there is only one block to

send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set as well as the AC12EN bit. However, the uSDHC will automatically send a CMD12 to mark the end of the multi-block transfer.

### 10.3.5.3.2 Block Read

Information about Normal Read, DDR Read, Read with Pause, and DLL (Delay Line) in Read Path are detailed in the sections below.

#### 10.3.5.3.2.1 Normal Read

For block reads, the basic unit of data transfer is a block whose maximum size is stored in areas defined by the corresponding card specification. A CRC is appended to the end of each block, ensuring data transfer integrity. The CMD17, CMD18, CMD53, CMD60, CMD61, and so on, can initiate a block read. After completing the transfer, the card returns to the Transfer State. For multi blocks read, data blocks will be continuously transferred until a stop command is issued.

The software flow to read from a card incorporates the internal DMA and the read operation is a multi-block read with the Auto CMD12 enabled. For the other two methods (by means of external DMA or CPU polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to read from a card is described below:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
  - For SD/MMC, use SET\_BLOCKLEN (CMD16)
  - For SDIO cards or the I/O portion of SDCCombo cards, use IO\_RW\_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the uSDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the uSDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer read ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a read CRC error occurred, or some another error, occurred during the auto12 command sending and response receiving.

### 10.3.5.3.2.2 DDR Read

uSDHC supports dual data rate mode.

The software flow to write to a card in ddr mode is described below:

1. Check the card status, wait until the card is ready for data.
2. For eMMC4.4 card, block length only can be set to 512byte.
3. Set the uSDHC number block register (NOB), nob is 5 (for instance).
4. Set eMMC4.4 card to high speed mode, use SWITCH(CMD6).
5. Set eMMC4.4 card bus with (4-bit /8-bit ddr mode), use SWITCH(CMD6).
6. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The DDR\_EN bit should be set. The AC12EN bit should also be set.
7. Wait for the Transfer Complete interrupt.
8. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

### 10.3.5.3.2.3 Read with Pause

The read operation is not generally able to pause. Only the SDIO card (and SDCombo card working under I/O mode) supporting the Read Wait feature can pause during the read operation. If the SDIO card supports Read Wait (SRW bit in CCCR register is 1), the Driver can set the SABGREQ bit in the Protocol Control register to pause the transfer between the data blocks.

Before setting the SABGREQ bit, make sure the RWCTL bit in the Protocol Control register is set, otherwise the uSDHC will not assert the Read Wait signal during the block gap and data corruption occurs. It is recommended to set the RWCTL bit once the Read Wait capability of the SDIO card is recognized.

Like in the flow described in [Normal Read](#), the read with pause is shown with the same kind of read operation:

1. Check the SRW bit in the CCR register on the SDIO card to confirm the card supports Read Wait.
2. Set the RWCTL bit.
3. Check the card status and wait until the card is ready for data.
4. Set the card block length/size:

- For SD/MMC, use SET\_BLOCKLEN (CMD16)
  - For SDIO cards or the I/O portion of SDCombo cards, use IO\_RW\_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
5. Set the uSDHC block length register to be the same as the block length set for the card in Step 2.
  6. Set the uSDHC number block register (NOB), nob is 5 (for instance).
  7. Disable the buffer read ready interrupt, configure the DMA setting and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set
  8. Set the SABGREQ bit.
  9. Wait for the Transfer Complete interrupt.
  10. Clear the SABGREQ bit.
  11. Check the status bit to see if read CRC error occurred.
  12. Set the CREQ bit to continue the read operation.
  13. Wait for the Transfer Complete interrupt.
  14. Check the status bit to see if a read CRC error occurred, or some another error, occurred during the auto12 command sending and response receiving.

Like the write operation, it is possible to meet the ending block of the transfer when paused. In this case, the uSDHC will ignore the Stop At Block Gap Request and treat it as a command read operation.

Unlike the write operation, there is no remaining data inside the buffer when the transfer is paused. All data received before the pause will be transferred to the Host System. No matter if the Suspend Command is sent or not, the internal data buffer is not flushed.

If the Suspend Command is sent and the transfer is later resumed by means of a Resume Command, the uSDHC takes the command as a normal one accompanied with data transfer. It is left for the Driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set, as well as the AC12EN bit. However, the uSDHC will automatically send the CMD12 to mark the end of multi-block transfer.

#### 10.3.5.3.2.4 DLL (Delay Line) in Read Path

The DLL(Delay Line) is newly added to assist in sampling read data. The DLL provides the ability to programmatically select a quantized delay (in fractions of the clock period) regardless of on-chip variations such as process, voltage and temperature (PVT).

The reasons why the DLL is needed for uSDHC are 1.) the path of read data traveling from card to host varies. 2.) in SD/MMC DDR mode the minimum input setup and hold time are both at 2.5 ns. The data sampling window is so small that the delay of loopback clock needs to be accurate and consistent regardless of PVT. The DLL takes the divided card\_clk as the reference clock and loopback clock as the input clock. It then generates a delayed version of the input clock according to the programmed target delay.

The DLL can be disabled or bypassed, and it can also be manually set for a fixed delay in override mode. The override value set is the number of delay cells. In override mode, there is no need to set the DLL\_enable. Another DLL mode is target value mode. In this mode, the DLL will automatically adjust the number of delay cells according to target value set by user and PVT changes. Be aware that target value is in units of 1/32 of the clock reference period. If the card\_clk is 100Mhz, then the reference clock period is 10ns, setting target vaule of 16 means  $5\text{ns} = (16/32) * 10\text{ns}$ . Software can disable automatic update by setting dll\_gate\_update bit. Please refer to [Figure 10-54](#).

Since the user may change the frequency of the card\_clk from time to time by changing SDCLKFS[7:0]/DVS[3:0], the software must adjust the delay value to ensure it works correctly when the reference clock (card\_clk) is changed. The following is the correct flow, which should be ignored if DLL\_CTRL\_ENABLE is not set.

Step 1: Set DLL\_CTRL\_RESET bit

Step 2: Configure the SDCLKFS[7:0] and DVS[3:0]

Step 3: Wait until SDSTB is asserted

Step 4: clear DLL\_CTRL\_RESET bit

Step 5: Wait until both DLL\_STS\_SLV\_LOCK and DLL\_STS\_REF\_LOCK are asserted

Step 6: set DLL\_CTRL\_SLV\_FORCE\_UPD

Step 7: clear DLL\_CTRL\_SLV\_FORCE\_UPD

NOTE:Software should make sure the DLL\_CTRL\_SLV\_FORCE\_UPD is lasted for at least one card\_clk. So software may need to add some delay between step6 and step7.

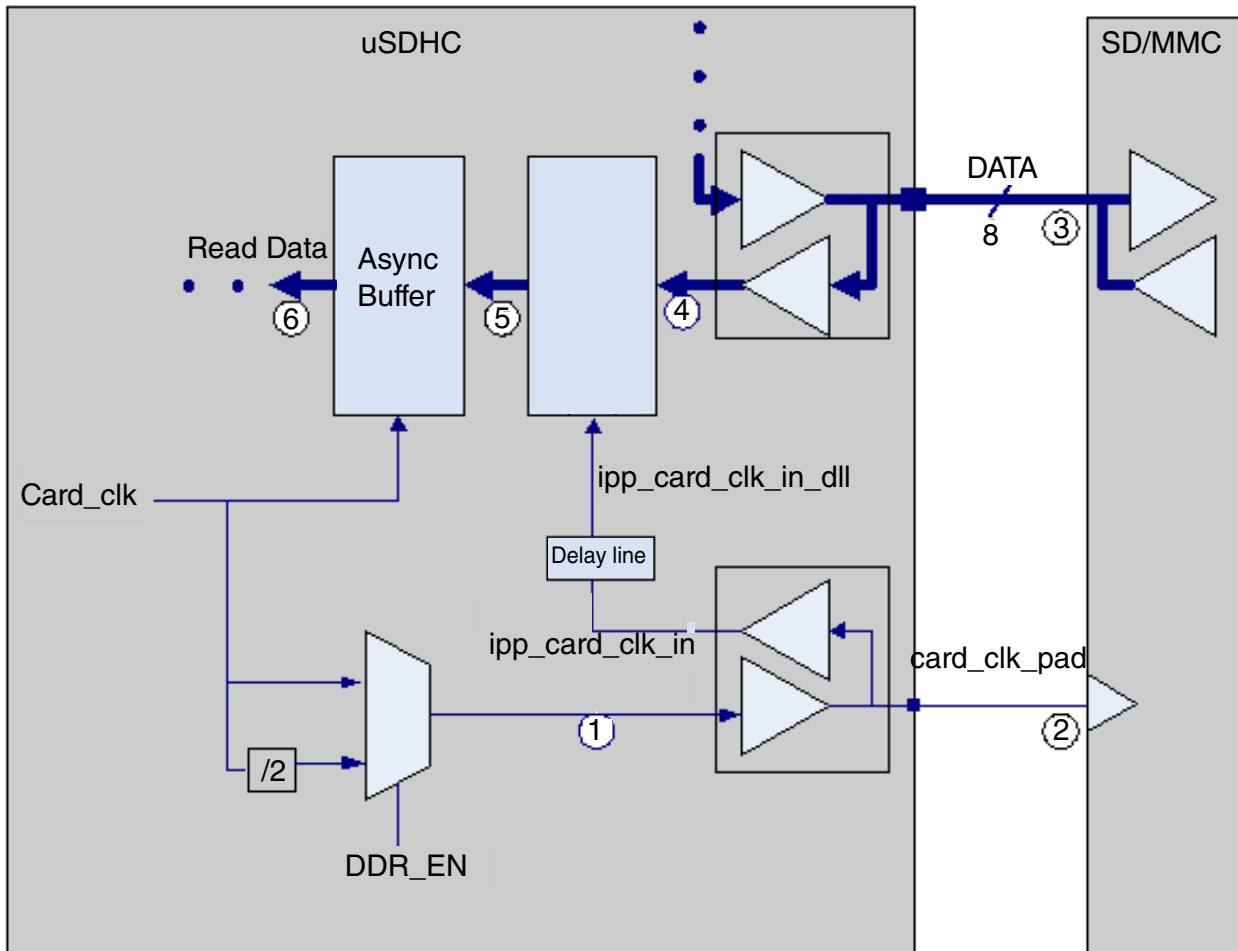

Figure 10-54. DLL(Delay Line) in Read Path

### 10.3.5.3.3 Suspend Resume

The uSDHC supports the Suspend Resume operations of SDIO cards, although slightly differently than the suggested implementation of Suspend in the SDIO card specification.

#### 10.3.5.3.3.1 Suspend

After setting the SABGREQ bit, the Host Driver may send a Suspend command to switch to another function of the SDIO card. The uSDHC does not monitor the content of the response, so it doesn't know if the Suspend command succeeded or not. Accordingly, it doesn't de-assert Read Wait for read pause. To solve this problem, the Driver shall not mark the Suspend command as a "Suspend", (i.e. setting the CMDTYP bits to 01). Instead, the Driver shall send this command as if it were a normal command, and only when the command succeeds, and the BS bit is set in the response, can the Driver send another command marked as "Suspend" to inform the uSDHC that the current transfer is suspended. As shown in the following sequence for Suspend operation:

1. Set the SABREQ bit to pause the current data transfer at block gap.
2. After the BGE bit is set, send the Suspend command to suspend the active function. The CMDTYP bit field must be 2'b00.
3. Check the BS bit of the CCCR in the response. If it is 1, repeat this step until the BS bit is cleared or abandon the suspend operation according to the Driver strategy.
4. Send another normal I/O command to the suspended function. The CMDTYP of this command must be 2'b01, so the uSDHC can detect this special setting and be informed that the paused operation has successfully suspended. If the paused transfer is a read operation, the uSDHC stops driving DATA2 and goes to the idle state.
5. Save the context registers in the system memory for later use, including the DMA System Address Register (for internal DMA operation), and the Block Attribute Register.
6. Begin operation for another function on the SDIO card.

#### 10.3.5.3.3.2 Resume

To resume the data transfer, a Resume command shall be issued:

1. To resume the suspended function, restore the context register with the saved value in step #5 of the Suspend operation above.
2. Send the Resume command. In the Transfer Type register, all bit fields are set to the value as if this were another ordinary data transfer, instead of a transfer resume (except the CMDTYP is set to 2'b10).
3. If the Resume command has responded, the data transfer will be resumed.

#### 10.3.5.3.4 ADMA Usage

To use the ADMA in a data transfer, the Host Driver must prepare the correct descriptor chain prior to sending the read/write command.

The steps to prepare the correct descriptor chain are:

1. Create a descriptor to set the data length that the current descriptor group is about to transfer. The data length should be even numbers of the block size.
2. Create another descriptor to transfer the data from the address setting in this descriptor. The data address must be at a page boundary (4kB address aligned).
3. If necessary, create a Link descriptor containing the address of the next descriptor. The descriptor group is created in steps 1 ~ 3.
4. Repeat steps 1 ~ 3 until all descriptors are created.
5. In the last descriptor, set the End flag to 1 and make sure the total length of all descriptors match the product of the block size and block number configured in the Block Attribute Register.

6. Set the ADMA System Address Register to the address of the first descriptor and set the DMAS field in the Protocol Control Register to 01 to select the ADMA.
7. Issue a write or read command with the DMAEN bit set to 1 in the Transfer Type Register.

Steps 1 ~ 5 are independent of step 6, so step 6 can finish before steps 1 ~ 5. Regarding the descriptor configuration, it is recommended not to use the Link descriptor as it requires extra system memory access.

### 10.3.5.3.5 Transfer Error

Information about CRC, Internal DMA, Transfer ADMA, and Auto CMD12 Errors are detailed in the sections below.

#### 10.3.5.3.5.1 CRC Error

It is possible at the end of a block transfer, that a write CRC status error or read CRC error occurs. For this type of error the latest block received shall be discarded. This is because the integrity of the data block is not guaranteed. It is recommended to discard the following data blocks and re-transfer the block from the corrupted one.

For a multi-block transfer, the Host Driver shall issue a CMD12 to abort the current process and start the transfer by a new data command. In this scenario, even when the AC12EN and BCEND bits are set, the uSDHC does not automatically send a CMD12 because the last block is not transferred. On the other hand, if it is within the last block that the CRC error occurs, an Auto CMD12 will be sent by the uSDHC. In this case, the Driver shall re-send or re-obtain the last block with a single block transfer.

#### 10.3.5.3.5.2 Internal DMA Error

During the data transfer with internal Simple DMA, if the DMA engine encounters some error on the AHB bus, the DMA operation is aborted and DMA Error interrupt is sent to the Host System. When acknowledged by such an interrupt, the Driver shall calculate the start address of data block in which the error occurs.

The start address can be calculated by either:

1. Reading the DMA System Address register. The error occurs during the previous burst. Taking the block size, the previous burst length and the start address of the next burst transfer into account, it is straight forward to obtain the start address of the corrupted block.

2. Reading the BLKCNT field of the Block Attribute register. By the number of blocks left, the total number to transfer, the start address of transfer, and the size of each block, the start address of corrupted block can be determined. When the BCEN bit is not set, the contents of the Block Attribute register does not change, so this method does not work.

When a DMA error occurs, it is recommended to abort the current transfer by means of a CMD12 (for multi block transfer), apply a reset for data, and re-start the transfer from the corrupted block to recover from the error.

#### 10.3.5.3.5.3 Transfer ADMA Error

There are 3 kinds of possible ADMA errors. The AHB transfer, invalid descriptor, and data-length mismatch errors. Whenever these errors occur, the DMA transfer stops and the corresponding error status bit is set.

For acknowledging the status, the Host Driver should recover the error as shown below and re-transfer from the place of interruption.

1. AHB transfer error: Such errors may occur during data transfer or descriptor fetch. For either scenario, it is recommended to retrieve the transfer context, reset for the data part and re-transfer the block that was corrupted, or the next block if no block is corrupted.
2. Invalid descriptor error: For such errors, it is recommended to retrieve the transfer context, reset for the data part and re-create the descriptor chain from the invalid descriptor and issue a new transfer. As the data to transfer now may be less than the previous setting, the data length configured in the new descriptor chain should match the new value.
3. Data-length mismatch error: It is similar to recover from this error. The Host Driver polls relating registers to retrieve the transfer context, apply a reset for the data part, configure a new descriptor chain, and make another transfer if there is data left. Like the previous scenario of the invalid descriptor error, the data length must match the new transfer.

#### 10.3.5.3.5.4 Auto CMD12 Error

After the last block of the multi block transfer is sent or received, and the AC12EN bit is set when the data transfer is initiated by the data command, the uSDHC automatically sends a CMD12 to the card to stop the transfer.

When errors with this command occur, it is recommended to the Driver to deal with the situations in the following manner:

1. Auto CMD12 response time-out. It is not certain whether the command is accepted by the card or not. The Driver should clear the Auto CMD12 error status bits and re-send the CMD12 until it is accepted by the card.
2. Auto CMD12 response CRC error. Since card responds to the CMD12, the card will abort the transfer. The Driver may ignore the error and clear the error status bit.
3. Auto CMD12 conflict error or not sent. The command is not sent, so the Driver shall send a CMD12 manually.

#### 10.3.5.3.6 Card Interrupt

The external cards can inform the Host Controller by means of some special signals. For the SDIO card, it can be the low level on the DATA1 line during some special period. The uSDHC only monitors the DATA1 line and supports the SDIO interrupt.

When the SDIO interrupt is captured by the uSDHC, and the Host System is informed by the uSDHC asserting the uSDHC interrupt line, the interrupt service from the Host Driver is called.

As the interrupt source is controlled by the external card, the interrupt from the SDIO card must be serviced before the CINT bit is cleared by written. Refer to [Card Interrupt Handling](#) for the card interrupt handling flow.

#### 10.3.5.4 Switch Function

A switch command shall be issued by the Host Driver to enable new features added to the SD/MMC spec. SD/MMC cards can transfer data at bus widths other than 1-bit. Different speed mode are also defined. To enable these features, a switch command shall be issued by the Host Driver.

For SDIO cards, the high speed mode/DDR50/SDR50/SDR104 are enabled by writing the EHS bit in the CCCR register after the SHS bit is confirmed. For SD cards, the high speed mode/DDR50/SDR50/SDR104 are queried and enabled by a CMD6 (with the mnemonic symbol as SWITCH\_FUNC). For MMC cards, the high speed mode/HS400 are queried by a CMD8 and enabled by a CMD6 (with the mnemonic symbol as SWITCH).

The SDR4-bit, SDR8-bit, DDR4-bit and DDR8-bit width of the MMC is also enabled by the SWITCH command, but with a different argument.

These new functions can also be disabled by a software reset. For SDIO cards it can be done by setting the RES bit in the CCCR register. For other cards, it can be accomplished by issuing a CMD0. This method of restoring to the normal mode is not recommended because a complete identification process is needed before the card is ready for data transfer.

For the sake of simplicity, the following pseudocode examples do not show current capability check, which is recommended in the function switch process.

#### 10.3.5.4.1 Query, Enable and Disable SDIO High Speed Mode

```
enable_sdio_high_speed_mode(void)
{
send CMD52 to query bit SHS at address 0x13;
if (SHS bit is '0') report the SDIO card does not support high speed mode and return;
send CMD52 to set bit EHS at address 0x13 and read after write to confirm EHS bit is set;
change clock divisor value or configure the system clock feeding into USDHC to generate the
card_clk of around 50MHz;
(data transactions like normal peers)
}
disable_sdio_high_speed_mode(void)
{
send CMD52 to clear bit EHS at address 0x13 and read after write to confirm EHS bit is
cleared;
change clock divisor value or configure the system clock feeding into USDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

#### 10.3.5.4.2 Query, Enable and Disable SD High Speed Mode/SDR50/SDR104/DDR50

```
enable_sd_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0xFFFFFx and read 64 bytes of data accompanying the R1 response;
(high speed mode,x=1; SDR50,x=2; SDR104,x=3; DDR50,x=4;)
wait data transfer done bit is set;
check if the bit x of received 512 bits is set;
if (bit 401 is '0') report the SD card does not support high speed mode and return;
if (bit 402 is '0') report the SD card does not support SDR50 mode and return;
if (bit 403 is '0') report the SD card does not support SDR104 mode and return;
if (bit 404 is '0') report the SD card does not support DDR50 mode and return;
send CMD6, with argument 0x80FFFFFx and read 64 bytes of data accompanying the R1 response;
(high speed mode,x=1; SDR50,x=2; SDR104 x=3; DDR50 x=4;)
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into USDHC to generate the
card_clk of around 50MHz for high speed mode, 100Mhz for SDR50, 200Mhz for SDR104, 50Mhz for
DDR50;
(data transactions like normal peers)
}
disable_sd_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0x80FFFFF0 and read 64 bytes of data accompanying the R1 response;
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into USDHC to generate the
card_clk of the desired value below 25MHz;
```

```
(data transactions like normal peers)
}
```

### 10.3.5.4.3 Query, Enable and Disable MMC High Speed Mode

```
enable_mmc_high_speed_mode(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support high speed mode and
return;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
extract the value of CARD_TYPE field to check the 'high speed mode' in this MMC is 26MHz or
52MHz;
send CMD6 with argument 0x1B90100;
send CMD13 to wait card ready (busy line released);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 1;
if (HS_TIMING is not 1) report MMC switching to high speed mode failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of around 26MHz or 52MHz according to the CARD_TYPE;
(data transactions like normal peers)
}
disable_mmc_high_speed_mode(void)
{
send CMD6 with argument 0x2B90100;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 0;
if (HS_TIMING is not 0) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 20MHz;
(data transactions like normal peers)
}
```

### 10.3.5.4.4 Set MMC Bus Width

```
change_mmc_bus_width(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support multiple bit width and
return;
send CMD6 with argument 0x3B70x00; (8-bit(dual data rate), x=6; 4-bit(dual data rate), x=5;8-
bit, x=2; 4-bit, x=1; 1-bit, x=0)
send CMD13 to wait card ready (busy line released);
(data transactions like normal peers)
}
```

## 10.3.5.5 ADMA Operation

Code for ADMA1 Operation and ADMA2 Operation can be found here.

### 10.3.5.5.1 ADMA1 Operation

```
Set_adma1_descriptor
{
if (to start data transfer) {
// Make sure the address is 4KB align.
```

```

Set 'Set' type descriptor;
{
Set Act bits to 01;
Set [31:12] bits data length (byte unit);
}
Set 'Tran' type descriptor;
{
Set Act bits to 10;
Set [31:12] bits address (4KB align);
}
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to 11;
Set [31:12] bits the next descriptor address (4KB aligned);
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set End bit to 1;
}
if (to generate interrupt for this descriptor) {
Set Int bit to 1;
}
Set Valid bit to 1;
}

```

### 10.3.5.5.2 ADMA2 Operation

```

Set_adma2_descriptor
{
if (to start data transfer) {
// Make sure the address is a 32-bit boundary (lower 2-bit are always '00').
Set higher 32-bit of descriptor for this data transfer initial address;
Set [31:16] bits data length (byte unit);
Set Act bits to '10';
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to '11';
// Make sure the address is 32-bit boundary (lower 2-bit are always set to '00').
Set higher 32-bit of descriptor for the next descriptor address;
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set 'End' bit '1';
}
if (to generate interrupt for this descriptor) {
Set 'Int' bit '1';
}
Set the 'Valid' bit to '1';
}

```

### 10.3.5.6 Fast Boot Operation

#### 10.3.5.6.1 Normal fast boot flow

1. Software must configure `init_active` bit (system control register bit 27) to make sure 74 card clocks are finished.

2. Software must configure the MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 0 (normal fast boot), and bit 4 to select the ack mode or not. If the data will be sent through DMA mode, the software should configure bit 7 to enable the automatic stop at block gap feature, and configure bit 3-bit 0 to select the ack timeout value according to the SD CLK frequency.
3. Software then needs to configure the Block Attributes Register to set the block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes.
4. Software must configure the Protocol control register to set DTW (data transfer width). If in DDR fast boot mode, DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software needs to configure the Command Argument Register to set argument if needed (no need in normal fast boot).
6. Software must configure the Transfer Type Register to start the boot process. In normal boot mode, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN are kept at the default value. DPSEL bit is set to 1, DTDSEL is set to 1, MSBSEL is set to 1.
7. DMAEN should be configured as 0 in polling mode. And if BCEN is configured as 1, it is recommended to configure the number of blocks in the Block Attributes Register to the maximum value. If in DDR fast boot mode, DDR\_EN needs to be set to 1.
8. When the step 6 is configured, the boot process will begin. Software needs to poll the data buffer ready status to read the data from the buffer in time. If a boot timeout happens (ack times out or the first data read times out), an interrupt will be triggered, and software must configure MMC Boot Register to bit 6 to 0 to disable boot. This makes CMD high, then after at least 56 clocks, it is ready to begin a normal initialization process.
9. If there is no timeout, software needs to determine when the data read is finished and then configure MMC Boot Register bit 6 to 0 to disable boot. This will make CMD line high and command completed asserted. After at least 56 clocks, it is ready to begin normal initialization process.
10. Reset the host and then can begin the normal process.

#### 10.3.5.6.2 Alternative fast boot flow

1. Software needs to configure init\_active bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software needs to configure MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 1 (alternative boot), and bit 4 to select the ack mode or not. If data needs to be sent through DMA mode, then configure bit 7 to enable the automatic stop at block gap feature. Software should also configure bit 3-bit 0 to select the ack timeout value according to the SD clock frequency.

3. Software then needs to configure Block Attributes Register to set the block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes.
4. Software needs to configure the Protocol control register to set the DTW (data transfer width). If in ddr fast boot mode, DTW only can be configure to 4-bit/8-bit dataline mode.
5. Software needs to configure Command Argument Register to set argument to 0xFFFFFFFFFA.
6. Software needs to configure the Transfer Type Register to start the boot process by CMD0 with 0xFFFFFFFFFA argument . In alternative boot, CMDINX, CMDTYP, RSPTYP, C ICEN, CCCEN, AC12EN, BCEN and DMAEN are kept default value. DPSEL bit is set to 1, DTDSEL is set to 1, MSBSEL is set to 1. Note DMAEN should be configured as 0 in polling mode. And if BCEN is configured as 1 in polling mode, it is recommended to configure the block count in the Block Attributes Register to the maximum value. If in DDR fast boot mode, DDR\_EN needs to be set to 1.
7. When the step 6 is configured, the boot process will begin. Software needs to poll the data buffer ready status to read the data from the buffer in time. If there is a boot timeout (ack data timeout in 50ms or data timeout in 1s), the host will send out the interrupt and software needs to send CMD0 with reset and then configure the boot enable bit to 0 to stop this process..
8. If there is no time out, software needs to decide when to stop the boot process, and send out the CMD0 with reset and then after the command is completed, configure the MMC Boot Register bit 6 to stop the process. After 8 clocks from the command completion, the slave (card) is ready for the identification step.
9. Reset the host and then begin the normal process.

### 10.3.5.6.3 Fast boot application case (in DMA mode)

In the boot application case, because the image destination and the image size are contained in the beginning of the image, it is necessary to switch DMA parameters on the fly during MMC fast boot.

In fast boot, the host can use ADMA2 (Advanced DMA2) with two destinations.

The detail flow is described below:

1. Software needs to configure INIT\_ACTIVE bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software needs to configure the MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot); and bit 5 to 0 (normal fast boot) or 1 (alternative boot); and bit 4 to select the ack mode or not. In DMA mode, configure bit 7 to 1 to enable the automatic stop at block gap feature. Also configure bits[31-16] to set the (BLK\_CNT - VALUE1). Here VALUE1 is the value of the block count that needs to transfer the

- first time, so that that the host will stop at the block gap when the uSDHC controller gets VALUE1 blocks from the device. Also configure bits[3-0] to select the ack timeout value according to the SD clock frequency.
3. Software then needs to configure the Block Attributes Register to set block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes. In DMA mode, it is recommended to set the block count (BLK\_CNT) to the max value (16'hffff).
  4. Software needs to configure Protocol Control Register to set DTW (data transfer width). If in DDR fast boot mode, the DTW only can be configured to 4-bit/8-bit dataline mode.
  5. Software enable ADMA2 by configuring Protocol Control Register bits [9-8].
  6. Software need to set at least three pairs ADMA2 descriptor in boot memory (ie, in IRAM, at least 6 word). The first pair descriptor define the start address (ie, IRAM) and data length (ie, 512 byte \* VALUE1) of first part boot code. Software also need to set the second pair descriptor, the second start address (any value that is writeable), data length is suggest to set 1~2 word (record as VALUE2). Note: the second couple desc also transfer useful data even at least 1 word. Because our ADMA2 can't support 0 data\_length data transfer descriptor.
  7. Software needs to configure Command Argument Register to set argument to 0xFFFFFFFF in alternative fast boot, and don't need set in normal fast boot.
  8. Software needs to configure Transfer Type Register to start the boot process. CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN are kept default value. DPSEL bit is set to 1, DTDSEL is set to 1, MSBSEL is set to 1. DMAEN is configured as 1 in DMA mode. And if BCEN is configured as 1, better to configure blk no in Block Attributes Register to the max value. And if in ddr fast boot mode, DDR\_EN need to be set to 1.
  9. When the step 8 is configured, boot process will begin, the first VALUE1 block number data has transfer. Software need to polling TC bit (bit1 in Interrupt Status Register) to determine first transfer is end. Also software need to polling BGE bit (bit2 in Interrupt Status Register) to determine if first transfer stop at block gap.
  10. When TC, BGE bit is 1, SW can analyzes the first code of VALUE1 block, initializes the new memory device, if required, and sets the third pair of descriptors to define the start address and length of the remaining part of boot code (VALUE3 the remain boot code block). Remember set the last descriptor with END.
  11. Software needs to configure MMC Boot Register (offset 0xc4) again. Set bit 6 to 1 (enable boot); and bit 5 to 0 (normal fast boot), to 1 (alternative boot); and bit 4 to select the ack mode or not. In DMA mode, configure bit 7 to 1 for enable automatically stop at block gap feature. Also configure bit31-bit16 to set the  $(BLK\_CNT - (VALUE1 + 1 + VALUE3))$ , that host will stop at block gap when *the uSDHC controller gets (VALUE1+1+VALUE3) blocks from device totally include the blocks received in step 9*. And need to configure bit 3-bit0 to select the ack

timeout value according to the sd clk frequency. Please note, Software doesn't need to configure the *BLK\_CNT* again, because it's counted down automatically by the uSDHC controller.

12. Software needs to clear TC and BGE bit. And software needs to clear SABGREQ(bit 16 in Protocol control register), and set CREQ(bit17 Protocol control register) to 1 to resume the data transfer. Host will transfer the VALUE2 and VALUE3 data to the destination that is set by descriptor.
13. Software need to polling BGE bit to determine if the fast boot is over.

Note:

1. When ADMA boot flow is started, for uSDHC, it is like a normal ADMA read operation. So setting ADMA2 descriptor as the normal ADMA2 transfer.
2. Need a few words length memory to keep descriptor.
3. For the 1~2 word data in second descriptor setting, it is the useful data, so software need to deal the data due to the application case.

### 10.3.6 Commands for MMC/SD/SDIO

A table containing the list of commands for the MMC/SD/SDIO cards can be found here.

Refer to the corresponding specifications for more details about the command information.

There are four kinds of commands defined to control the MultiMediaCard:

1. broadcast commands (bc), no response.
2. broadcast commands with response (bcr), response from all cards simultaneously.
3. addressed (point-to-point) commands (ac), no data transfer on the DATA.
4. addressed (point-to-point) data transfer commands (adtc).

Response: a response is a token which is sent from the card to the host as an answer to a previously received command. A response is transferred serially on the CMD line.

**Table 10-42. Commands for MMC/SD/SDIO Cards**

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD0	bc	[31:0] stuff bits	-	GO_IDLE_STATE	Resets all MMC and SD memory cards to idle state.
CMD1	bcr	[31:0] OCR without busy	R3	SEND_OP_COND	Asks all MMC and SD Memory cards in idle state to send their operation conditions register contents in the response on the CMD line.

*Table continues on the next page...*

**Table 10-42. Commands for MMC/SD/SDIO Cards (continued)**

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD2	bcr	[31:0] stuff bits	R2	ALL_SEND_CID	Asks all cards to send their CID numbers on the CMD line.
CMD3 <sup>1</sup>	ac	[31:6] RCA [15:0] stuff bits	R1 R6 (SDIO)	SET/ SEND_RELATIVE_AD DR	Assigns relative address to the card.
CMD4	bc	[31:0] DSR [15:0] stuff bits	-	SET_DSR	Programs the DSR of all cards.
CMD5	bc	[31:0] OCR without busy	R4	IO_SEND_OP_COND	Asks all SDIO cards in idle state to send their operation conditions register contents in the response on the CMD line.
CMD6 <sup>2</sup>	adtc	[31] Mode 0: Check function 1: Switch function [30:8] Reserved for function groups 6 ~ 3 (All 0 or 0xFFFF) [7:4] Function group1 for command system [3:0] Function group2 for access mode	R1	SWITCH_FUNC	Checks switch ability (mode 0) and switch card function (mode 1). Refer to "SD Physical Specification V1.1" for more details.
CMD6 <sup>3</sup>	ac	[31:26] Set to 0 [25:24] Access [23:16] Index [15:8] Value [7:3] Set to 0 [2:0] Cmd Set	R1b	SWITCH	Switches the mode of operation of the selected card or modifies the EXT_CSD registers. Refer to "The MultiMediaCard System Specification Version 4.0 Final draft 2" for more details.
CMD7	ac	[31:6] RCA [15:0] stuff bits	R1b	SELECT/ DESELECT_CARD	Toggles a card between the stand-by and transfer states or between the programming and disconnect states. In both cases, the card is selected by its own relative address and gets deselected by any other address. Address 0 deselects all.
CMD8	adtc	[31:0] stuff bits	R1	SEND_EXT_CSD	The card sends its EXT_CSD register as a block of data, with a block size of 512 bytes.
CMD9	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CSD	Addressed card sends its card-specific data (CSD) on the CMD line.
CMD10	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CID	Addressed card sends its card-identification (CID) on the CMD line.

Table continues on the next page...

Table 10-42. Commands for MMC/SD/SDIO Cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD11	adtc	[31:0] data address	R1	READ_DAT_UNTIL_STOP	Reads data stream from the card, starting at the given address, until a STOP_TRANSMISSION follows.
CMD12	ac	[31:0] stuff bits	R1b	STOP_TRANSMISSION	Forces the card to stop transmission.
CMD13	ac	[31:6] RCA [15:0] stuff bits	R1	SEND_STATUS	Addressed card sends its status register.
CMD14	Reserved				
CMD15	ac	[31:6] RCA [15:0] stuff bits	-	GO_INACTIVE_STATE	Sets the card to inactive state in order to protect the card stack against communication breakdowns.
CMD16	ac	[31:0] block length	R1	SET_BLOCKLEN	Sets the block length (in bytes) for all following block commands (read and write). Default block length is specified in the CSD.
CMD17	adtc	[31:0] data address	R1	READ_SINGLE_BLOCK	Reads a block of the size selected by the SET_BLOCKLEN command.
CMD18	adtc	[31:0] data address	R1	READ_MULTIPLE_BLOCK	Continuously transfers data blocks from card to host until interrupted by a stop command.
CMD19	Reserved				
CMD20	adtc	[31:0] data address	R1	WRITE_DAT_UNTIL_STOP	Writes data stream from the host, starting at the given address, until a STOP_TRANSMISSION follows.
CMD21-23	Reserved				
CMD24	adtc	[31:0] data address	R1	WRITE_BLOCK	Writes a block of the size selected by the SET_BLOCKLEN command.
CMD25	adtc	[31:0] data address	R1	WRITE_MULTIPLE_BLOCK	Continuously writes blocks of data until a STOP_TRANSMISSION follows.
CMD26	adtc	[31:0] stuff bits	R1	PROGRAM_CID	Programming of the card identification register. This command shall be issued only once per card. The card contains hardware to prevent this operation after the first programming. Normally this command is reserved for the manufacturer.
CMD27	adtc	[31:0] stuff bits	R1	PROGRAM_CSD	Programming of the programmable bits of the CSD.
CMD28	ac	[31:0] data address	R1b	SET_WRITE_PROT	If the card has write protection features, this command sets the write protection bit of the addressed group. The properties of write protection are coded in the card specific data (WP_GRP_SIZE).

Table continues on the next page...

**Table 10-42. Commands for MMC/SD/SDIO Cards (continued)**

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD29	ac	[31:0] data address	R1b	CLR_WRITE_PROT	If the card provides write protection features, this command clears the write protection bit of the addressed group.
CMD30	adtc	[31:0] write protect data address	R1	SEND_WRITE_PROT	If the card provides write protection features, this command asks the card to send the status of the write protection bits.
CMD31	Reserved				
CMD32	ac	[31:0] data address	R1	TAG_SECTOR_START	Sets the address of the first sector of the erase group.
CMD33	ac	[31:0] data address	R1	TAG_SECTOR_END	Sets the address of the last sector in a continuous range within the selection of a single sector to be selected for erase.
CMD34	ac	[31:0] data address	R1	UNTAG_SECTOR	Removes one previously selected sector from the erase selection.
CMD35	ac	[31:0] data address	R1	TAG_ERASE_GROUP_START	Sets the address of the first erase group within a range to be selected for erase.
CMD36	ac	[31:0] data address	R1	TAG_ERASE_GROUP_END	Sets the address of the last erase group within a continuous range to be selected for erase.
CMD37	ac	[31:0] data address	R1	UNTAG_ERASE_GROUP	Removes one previously selected erase group from the erase selection.
CMD38	ac	[31:0] stuff bits	R1b	ERASE	Erase all previously selected sectors.
CMD39	ac	[31:0] RCA [15] register write flag [14:8] register address [7:0] register data	R4	FAST_IO	Used to write and read 8-bit (register) data fields. The command addresses a card, and a register, and provides the data for writing if the write flag is set. The R4 response contains data read from the address register. This command accesses application dependent registers which are not defined in the MMC standard.
CMD40	bcr	[31:0] stuff bits	R5	GO_IRQ_STATE	Sets the system into interrupt mode.
CMD41	Reserved				
CDM42	adtc	[31:0] stuff bits	R1b	LOCK_UNLOCK	Used to set/reset the password or lock/unlock the card. The size of the data block is set by the SET_BLOCK_LEN command.
CMD43~51	Reserved				

*Table continues on the next page...*

Table 10-42. Commands for MMC/SD/SDIO Cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD52	ac	[31:0] stuff bits	R5	IO_RW_DIRECT	Access a single register within the total 128k of register space in any I/O function.
CMD53	ac	[31:0] stuff bits	R5	IO_RW_EXTENDED	Accesses a multiple I/O register with a single command. Allows the reading or writing of a large number of I/O registers.
CMD54	Reserved				
CMD55	ac	[31:16] RCA [15:0] stuff bits	R1	APP_CMD	Indicates to the card that the next command is an application specific command rather than a standard command.
CMD56	adtc	[31:1] stuff bits [0]: RD/WR	R1b	GEN_CMD	Used either to transfer a data block to the card or to get a data block from the card for general purpose / application specific commands. The size of the data block is set by the SET_BLOCK_LEN command.
CMD57-59	Reserved				
CMD60	adtc	[31] WR [30:24] stuff bits [23:16] address [15:8] stuff bits [7:0] byte count	R1b	RW_MULTIPLE_REGISTER	These registers are used to control the behavior of the device and to retrieve status information regarding the operation of the device. All Status and Control registers are WORD (32-bit) in size and are WORD aligned. CMD60 shall be used to read and write these registers.
CMD61	adtc	[31] WR [30:16] stuff bits [15:0] data unit count	R1b	RW_MULTIPLE_BLOCK	The host issues a RW_MULTIPLE_BLOCK (CMD61) to begin the data transfer.
CMD62-63	Reserved				
ACMD6 <sup>4</sup>	ac	[31:2] stuff bits [1:0] bus width	R1	SET_BUS_WIDTH	Defines the data bus width ('00'=1bit or '10'=4bit bus) to be used for data transfer. The allowed data bus widths are given in SCR register.
ACMD13 <sup>4</sup>	adtc	[31:0] stuff bits	R1	SD_STATUS	Send the SD Memory Card status.
ACMD22 <sup>4</sup>	adtc	[31:0] stuff bits	R1	SEND_NUM_WR_SECTORS	Send the number of the written sectors (without errors). Responds with 32-bit plus the CRC data block.
ACMD23 <sup>4</sup>	ac	[31:23] stuff bits [22:0] Number of blocks	R1	SET_WR_BLK_ERASE_COUNT	Set the number of write blocks to be pre-erased before writing (to be used for fast Multiple Block WR command). "1"=default(one write block).

Table continues on the next page...

**Table 10-42. Commands for MMC/SD/SDIO Cards (continued)**

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
ACMD41 <sup>4</sup>	bcr	[31:0] OCR	R3	SD_APP_OP_COND	Asks the accessed card to send its operating condition register (OCR) contents in the response on the CMD line.
ACMD42 <sup>4</sup>	ac	[31:1] stuff bits [0] set_cd	R1	SET_CLR_CARD_DETECT	Connect(1)/Disconnect(0) the 50KOhm pull-up resistor on CD_B/DATA3 of the card.
ACMD51 <sup>4</sup>	adtc	[31:0] stuff bits	R1	SEND_SCR	Reads the SD Configuration Register (SCR).

1. CMD3 differs for MMC and SD cards. For MMC cards, it is referred to as SET\_RELATIVE\_ADDR, with a response type of R1. For SD cards, it is referred to as SEND\_RELATIVE\_ADDR, with a response type of R6 (with RCA inside).
2. CMD6 differs completely between high speed MMC cards and high speed SD cards. Command SWITCH\_FUNC is for high speed SD cards.
3. Command SWITCH is for high speed MMC cards. The Index field can contain any value from 0-255, but only values 0-191 are valid. If the Index value is in the 192-255 range the card does not perform any modification and the SWITCH\_ERROR status bit in the EXT\_CSD register is set. The Access Bits are shown in [Table 2](#).
4. ACMDs shall be preceded with the APP\_CMD command. (Commands listed are used for SD only, other SD commands not listed are not supported on this module).

The Access Bits for the EXT\_CSD Access Modes are shown below.

**Table 10-43. EXT\_CSD Access Modes**

Bits	Access Name	Operation
00	Command Set	The command set is changed according to the Cmd Set field of the argument
01	Set Bits	The bits in the pointed byte are set, according to the 1 bits in the Value field.
10	Clear Bits	The bits in the pointed byte are cleared, according to the 1 bits in the Value field.
11	Write Byte	The Value field is written into the pointed byte.

## 10.3.7 Software Restrictions

### 10.3.7.1 Initialization Active

The driver cannot set INITA bit in System Control register when any of the command line or data lines is active, so the driver must ensure both CDIHB and CIHB bits are cleared.

### 10.3.7.2 Software Polling Procedure

For polling read or write, once the software begins a buffer read or write, it must access exactly the number of times as the values set in the Watermark Level Register; moreover, if the block size is not a multiple of the value in Watermark Level Register (read and write respectively), the software must access exactly the remaining number of words at the end of each block.

For example, for a read operation, if the RD\_WML is 4, indicating the watermark level is 16 bytes, block size is 40 bytes, and the block number is 2, then the access times for the burst sequence in the whole transfer process must be 4, 4, 2, 4, 4, 2.

### 10.3.7.3 Suspend Operation

In order to suspend the data transfer, the software must inform uSDHC that the suspend command is successfully accepted. To achieve this, after the Suspend command is accepted by the SDIO card, software must send another normal command marked as suspend command (CMDTYP bits set as '01') to inform uSDHC that the transfer is suspended.

If software needs to resume the suspended transfer, it should read the value in BLKCNT register to save the remaining number of blocks before sending the normal command marked as suspend, otherwise on sending such 'suspend' command, uSDHC will regard the current transfer is aborted and change BLKCNT register to its original value, instead of keeping the remained number of blocks.

### 10.3.7.4 Data Length Setting

For either ADMA (ADMA1 or ADMA2) transfer, the data in the data buffer must be word aligned, so the data length set in the descriptor must be a multiple of 4.

### 10.3.7.5 (A)DMA Address Setting

To configure ADMA1/ADMA2/DMA address register, when TC bit is set, the register will always update itself with the internal address value to support dynamic address synchronization, so the software must ensure that the TC bit is cleared prior to configuring ADMA1/ADMA2/DMA address register.

### 10.3.7.6 Data Port Access

Data Port does not support parallel access. For example, during an external DMA access, it is not allowed to write any data to the Data Port by CPU; or during a CPU read operation, it is also prohibited to write any data to the Data Port, by either CPU or external DMA. Otherwise the data would be corrupted inside the uSDHC buffer.

### 10.3.7.7 Change Clock Frequency

uSDHC does not automatically gate off the card clock when the Host Driver changes the clock frequency. To prevent possible glitch on the card clock, clear the FRC\_SDCLK\_ON bit when changing clock divisor value(SDCLKFS or DVS in System Control Register) or setting RSTA bit.

Also before changing the clock divisor value, Host Driver should make sure the SDSTB bit is high.

### 10.3.7.8 Multi-block Read

For pre-defined multi-block read operation, i.e., the number of blocks to read has been defined by previous CMD23 for MMC, or pre-defined number of blocks in CMD53 for SDIO/SDCombo, or whatever multi-block read without abort command at card side, an abort command, either automatic or manual CMD12/CMD52, is still required by uSDHC after the pre-defined number of blocks are done, to drive the internal state machine to idle mode.

In this case, the card may not respond to this extra abort command and uSDHC will get Response Timeout. It is recommended to manually send an abort command with RSPTYP[1:0] both bits cleared.

## 10.3.8 uSDHC Memory Map/Register Definition

This section includes the module memory map and detailed descriptions of all registers.

See the table below for the register memory map for the uSDHC. All these registers only support 32-bit accesses.

### NOTE

The uSDHC registers are 32-bit wide and only support 32-bit access.

### uSDHC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
30B4_0000	DMA System Address (uSDHC1_DS_ADDR)	32	R/W	0000_0000h	<a href="#">10.3.8.1/2795</a>
30B4_0004	Block Attributes (uSDHC1_BLK_ATT)	32	R/W	0000_0000h	<a href="#">10.3.8.2/2796</a>

## 10.3.8.1 DMA System Address (uSDHCx\_DS\_ADDR)

This register contains the physical system memory address used for DMA transfers.

Address: Base address + 0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	DS_ADDR																0															
W	DS_ADDR																0															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**uSDHCx\_DS\_ADDR field descriptions**

Field	Description
31–2 DS_ADDR	<p>DMA System Address:</p> <p>This register contains the 32-bit system memory address for a DMA transfer. Since the address must be word (4 bytes) aligned, the least 2 bits are reserved, always 0. When the uSDHC stops a DMA transfer, this register points to the system address of the next contiguous data position. It can be accessed only when no transaction is executing (i.e. after a transaction has stopped). Read operation during transfers may return an invalid value. The Host Driver shall initialize this register before starting a DMA transaction. After DMA has stopped, the system address of the next contiguous data position can be read from this register.</p> <p>This register is protected during a data transfer. When data lines are active, write to this register is ignored. The Host driver shall wait, until the DLA bit in the Present State register is cleared, before writing to this register.</p> <p>The uSDHC internal DMA does not support a virtual memory system. It only supports continuous physical memory access. And due to AHB burst limitations, if the burst must cross the 1 KB boundary, uSDHC will automatically change SEQ burst type to NSEQ.</p> <p>Since this register supports dynamic address reflecting, when TC bit is set, it automatically alters the value of internal address counter, so SW cannot change this register when TC bit is set. Such restriction is also listed in <a href="#">Software Restrictions</a> .</p>
Reserved	This read-only field is reserved and always has the value 0.

**10.3.8.2 Block Attributes (uSDHCx\_BLK\_ATT)**

This register is used to configure the number of data blocks and the number of bytes in each block.

Address: Base address + 4h offset

**uSDHCx\_BLK\_ATT field descriptions**

Field	Description
31–16 BLKCNT	<p>Blocks Count For Current Transfer:</p> <p>This register is enabled when the Block Count Enable bit in the Transfer Mode register is set to 1 and is valid only for multiple block transfers. For single block transfer, this register will always read as 1. The Host Driver shall set this register to a value between 1 and the maximum block count. The uSDHC decrements the block count after each block transfer and stops when the count reaches zero. Setting the block count to 0 results in no data blocks being transferred.</p> <p>This register should be accessed only when no transaction is executing (i.e. after transactions are stopped). During data transfer, read operations on this register may return an invalid value and write operations are ignored.</p>

*Table continues on the next page...*

## uSDHCx\_BLK\_ATT field descriptions (continued)

Field	Description
	<p>When saving transfer content as a result of a Suspend command, the number of blocks yet to be transferred can be determined by reading this register. The reading of this register should be applied after transfer is paused by stop at block gap operation and before sending the command marked as suspend. This is because when Suspend command is sent out, uSDHC will regard the current transfer is aborted and change BLKCNT register back to its original value instead of keeping the dynamical indicator of remained block count.</p> <p>When restoring transfer content prior to issuing a Resume command, the Host Driver shall restore the previously saved block count.</p> <p><b>NOTE:</b> Although the BLKCNT field is 0 after reset, the read of reset value is 0x1. This is because when MSBSEL bit is indicating a single block transfer, the read value of BLKCNT is always 1.</p> <p>FFFF 65535 blocks  0002 2 blocks  0001 1 block  0000 Stop Count</p>
15–13 Reserved	This read-only field is reserved and always has the value 0.
BLKSIZE[12:0]	<p>Transfer Block Size:</p> <p>This register specifies the block size for block data transfers. Values ranging from 1 byte up to the maximum buffer size can be set. It can be accessed only when no transaction is executing (i.e. after a transaction has stopped). Read operations during transfers may return an invalid value, and write operations will be ignored.</p> <p>1000 4096 Bytes  800 2048 Bytes  200 512 Bytes  1FF 511 Bytes  004 4 Bytes  003 3 Bytes  002 2 Bytes  001 1 Byte  000 No data transfer</p>

## 10.3.8.3 Command Argument (uSDHCx\_CMD\_ARG)

This register contains the SD / MMC Command Argument.

Address: Base address + 8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																																
W																																
	CMDARG[31:0]																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**uSDHCx\_CMD\_ARG field descriptions**

Field	Description
CMDARG[31:0]	<p>Command Argument</p> <p>The SD / MMC Command Argument is specified as bits 39-8 of the Command Format in the SD or MMC Specification. This register is write protected when the Command Inhibit (CMD) bit in the Present State register is set.</p>

**10.3.8.4 Command Transfer Type (uSDHCx\_CMD\_XFR\_TYP)**

This register is used to control the operation of data transfers. The Host Driver shall set this register before issuing a command followed by a data transfer, or before issuing a Resume command. To prevent data loss, the uSDHC prevents writing to the bits, that are involved in the data transfer of this register, when data transfer is active. These bits are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN and DMAEN.

The Host Driver shall check the Command Inhibit DAT bit (CDIHB) and the Command Inhibit CMD bit (CIHB) in the Present State register before writing to this register. When the CDIHB bit in the Present State register is set, any attempt to send a command with data by writing to this register is ignored; when the CIHB bit is set, any write to this register is ignored.

On sending commands with data transfer involved, it is mandatory that the block size is non-zero. Block count must also be non-zero, or indicated as single block transfer (bit 5 of this register is '0' when written), or block count is disabled (bit 1 of this register is '0' when written), otherwise uSDHC will ignore the sending of this command and do nothing. For write command, with all above restrictions, it is also mandatory that the write protect switch is not active (WPSPL bit of Present State Register is '1'), otherwise uSDHC will also ignore the command.

If the commands with data transfer does not receive the response in 64 clock cycles, i.e., response time-out, uSDHC will regard the external device does not accept the command and abort the data transfer. In this scenario, the driver should issue the command again to re-try the transfer. It is also possible that for some reason the card responds the command but uSDHC does not receive the response, and if it is internal DMA (either simple DMA or ADMA) read operation, the external system memory is over-written by the internal DMA with data sent back from the card.

The table below shows the summary of how register settings determine the type of data transfer.

**Table 10-44. Transfer Type Register Setting for Various Transfer Types**

Multi/Single Block Select	Block Count Enable	Block Count	Function
0	Don't Care	Don't Care	Single Transfer
1	0	Don't Care	Infinite Transfer
1	1	Positive Number	Multiple Transfer
1	1	Zero	No Data Transfer

The table below shows the relationship between the Command Index Check Enable and the Command CRC Check Enable, in regards to the Response Type bits as well as the name of the response type.

**Table 10-45. Relationship Between Parameters and the Name of the Response Type**

Response Type	Index Check Enable	CRC Check Enable	Name of Response Type
00	0	0	No Response
01	0	1	R2
10	0	0	R3,R4
10	1	1	R1,R5,R6
11	1	1	R1b,R5b

- In the SDIO specification, response type notation for R5b is not defined. R5 includes R5b in the SDIO specification. But R5b is defined in this specification to specify that the uSDHC will check the busy status after receiving a response. For example, usually CMD52 is used with R5, but the I/O abort command shall be used with R5b.
- The CRC field for R3 and R4 is expected to be all 1 bits. The CRC check shall be disabled for these response types.

Address: Base address + Ch offset

## Ultra Secured Digital Host Controller (uSDHC)

### uSDHCx\_CMD\_XFR\_TYP field descriptions

Field	Description
31–30 Reserved	This read-only field is reserved and always has the value 0.
29–24 CMDINX[5:0]	Command Index These bits shall be set to the command number that is specified in bits 45-40 of the Command-Format in the SD Memory Card Physical Layer Specification and SDIO Card Specification.
23–22 CMDTYP[1:0]	Command Type There are three types of special commands: Suspend, Resume and Abort. These bits shall be set to 00b for all other commands. <ul style="list-style-type: none"> <li>Suspend Command: If the Suspend command succeeds, the uSDHC shall assume that the card bus has been released and that it is possible to issue the next command which uses the DATA line. Since the uSDHC does not monitor the content of command response, it does not know if the Suspend command succeeded or not. It is the Host Driver's responsibility to check the status of the Suspend command and send another command marked as Suspend to inform the uSDHC that a Suspend command was successfully issued. Refer to <a href="#">Suspend Resume</a> for more details. After the end bit of command is sent, the uSDHC de-asserts Read Wait for read transactions and stops checking busy for write transactions. In 4-bit mode, the interrupt cycle starts. If the Suspend command fails, the uSDHC will maintain its current state, and the Host Driver shall restart the transfer by setting the Continue Request bit in the Protocol Control register.</li> <li>Resume Command: The Host Driver re-starts the data transfer by restoring the registers saved before sending the Suspend Command and then sends the Resume Command. The uSDHC will check for a pending busy state before starting write transfers.</li> <li>Abort Command: If this command is set when executing a read transfer, the uSDHC will stop reads to the buffer. If this command is set when executing a write transfer, the uSDHC will stop driving the DATA line. After issuing the Abort command, the Host Driver should issue a software reset (Abort Transaction).</li> </ul> <p>11 Abort CMD12, CMD52 for writing I/O Abort in CCCR  10 Resume CMD52 for writing Function Select in CCCR  01 Suspend CMD52 for writing Bus Suspend in CCCR  00 Normal Other commands</p>
21 DPSEL	Data Present Select This bit is set to 1 to indicate that data is present and shall be transferred using the DATA line. It is set to 0 for the following: <ul style="list-style-type: none"> <li>Commands using only the CMD line (e.g. CMD52).</li> <li>Commands with no data transfer, but using the busy signal on DATA0 line (R1b or R5b e.g. CMD38)</li> </ul>

Table continues on the next page...

## uSDHCx\_CMD\_XFR\_TYP field descriptions (continued)

Field	Description
	<p><b>NOTE:</b> In resume command, this bit shall be set, and other bits in this register shall be set the same as when the transfer was initially launched. When the Write Protect switch is on, (i.e. the WPSPL bit is active as '0'), any command with a write operation will be ignored. That is to say, when this bit is set, while the DTSEL bit is 0, writes to the register Transfer Type are ignored.</p> <p>1 Data Present 0 No Data Present</p>
20 CICEN	<p>Command Index Check Enable</p> <p>If this bit is set to 1, the uSDHC will check the Index field in the response to see if it has the same value as the command index. If it is not, it is reported as a Command Index Error. If this bit is set to 0, the Index field is not checked.</p> <p>1 Enable 0 Disable</p>
19 CCEN	<p>Command CRC Check Enable</p> <p>If this bit is set to 1, the uSDHC shall check the CRC field in the response. If an error is detected, it is reported as a Command CRC Error. If this bit is set to 0, the CRC field is not checked. The number of bits checked by the CRC field value changes according to the length of the response. (Refer to RSPTYP[1:0] and <a href="#">Command Transfer Type (uSDHC_CMD_XFR_TYP)</a> .)</p> <p>1 Enable 0 Disable</p>
18 -	This field is reserved. Reserved
17–16 RSPTYP[1:0]	<p>Response Type Select</p> <p>00 No Response 01 Response Length 136 10 Response Length 48 11 Response Length 48, check Busy after response</p>
Reserved	This read-only field is reserved and always has the value 0.

## 10.3.8.5 Command Response0 (uSDHCx\_CMD\_RSP0)

This register is used to store part 0 of the response bits from the card.

Address: Base address + 10h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**uSDHCx\_CMD\_RSP0 field descriptions**

Field	Description
CMDRSP0[31:0]	Command Response 0 Refer to <a href="#">Command Response3 (uSDHC_CMD_RSP3)</a> for the mapping of command responses from the SD Bus to this register for each response type.

**10.3.8.6 Command Response1 (uSDHCx\_CMD\_RSP1)**

This register is used to store part 1 of the response bits from the card.

Address: Base address + 14h offset

**uSDHCx\_CMD\_RSP1 field descriptions**

Field	Description
CMDRSP1[31:0]	Command Response 1 Refer to <a href="#">Command Response3 (uSDHC_CMD_RSP3)</a> for the mapping of command responses from the SD Bus to this register for each response type.

**10.3.8.7 Command Response2 (uSDHCx\_CMD\_RSP2)**

This register is used to store part 2 of the response bits from the card.

Address: Base address + 18h offset

**uSDHCx\_CMD\_RSP2 field descriptions**

Field	Description
CMDRSP2[31:0]	Command Response 2 Refer to <a href="#">Command Response3 (uSDHC_CMD_RSP3)</a> for the mapping of command responses from the SD Bus to this register for each response type.

### 10.3.8.8 Command Response3 (uSDHCx\_CMD\_RSP3)

This register is used to store part 3 of the response bits from the card.

The table below describes the mapping of command responses from the SD Bus to Command Response registers for each response type. In the table, R[ ] refers to a bit range within the response data as transmitted on the SD Bus.

**Table 10-46. Response Bit Definition for Each Response Type**

Response Type	Meaning of Response	Response Field	Response Register
R1,R1b (normal response)	Card Status	R[39:8]	CMDRSP0
R1b (Auto CMD12 response)	Card Status for Auto CMD12	R[39:8]	CMDRSP3
R2 (CID, CSD register)	CID/CSD register [127:8]	R[127:8]	{CMDRSP3[23:0], CMDRSP2, CMDRSP1, CMDRSP0}
R3 (OCR register)	OCR register for memory	R[39:8]	CMDRSP0
R4 (OCR register)	OCR register for I/O etc.	R[39:8]	CMDRSP0
R5, R5b	SDIO response	R[39:8]	CMDRSP0
R6 (Publish RCA)	New Published RCA[31:16] and card status[15:0]	R[39:9]	CMDRSP0

This table shows that most responses with a length of 48 (R[47:0]) have 32-bits of the response data (R[39:8]) stored in the CMDRSP0 register. Responses of type R1b (Auto CMD12 responses) have response data bits (R[39:8]) stored in the CMDRSP3 register. Responses with length 136 (R[135:0]) have 120-bits of the response data (R[127:8]) stored in the CMDRSP0, 1, 2, and 3 registers.

To be able to read the response status efficiently, the uSDHC only stores part of the response data in the Command Response registers. This enables the Host Driver to efficiently read 32-bits of response data in one read cycle on a 32-bit bus system. Parts of the response, the Index field and the CRC, are checked by the uSDHC (as specified by the Command Index Check Enable and the Command CRC Check Enable bits in the Transfer Type register) and generate an error interrupt if any error is detected. The bit range for the CRC check depends on the response length. If the response length is 48, the uSDHC will check R[47:1], and if the response length is 136 the uSDHC will check R[119:1].

Since the uSDHC may have a multiple block data transfer executing concurrently with a CMD\_wo\_DAT command, the uSDHC stores the Auto CMD12 response in the CMDRSP3 register. The CMD\_wo\_DAT response is stored in CMDRSP0. This allows

## Ultra Secured Digital Host Controller (uSDHC)

the uSDHC to avoid overwriting the Auto CMD12 response with the CMD\_wo\_DAT and vice versa. When the uSDHC modifies part of the Command Response registers, as shown in the table above, it preserves the unmodified bits.

Address: Base address + 1Ch offset

### uSDHCx\_CMD\_RSP3 field descriptions

Field	Description
CMDRSP3[31:0]	Command Response 3  Refer to <a href="#">Command Response3 (uSDHC_CMD_RSP3)</a> for the mapping of command responses from the SD Bus to this register for each response type.

## 10.3.8.9 Data Buffer Access Port (uSDHCx\_DATA\_BUFF\_ACC\_PORT)

This is a 32-bit data port register used to access the internal buffer.

Address: Base address + 20h offset

### uSDHCx\_DATA\_BUFF\_ACC\_PORT field descriptions

Field	Description
DATCONT[31:0]	Data Content  The Buffer Data Port register is for 32-bit data access by the ARM platform or the external DMA. When the internal DMA is enabled, any write to this register is ignored, and any read from this register will always yield 0s.

## 10.3.8.10 Present State (uSDHCx\_PRES\_STATE)

The Host Driver can get status of the uSDHC from this 32-bit read only register.

- The Host Driver can issue CMD0, CMD12, CMD13 (for memory) and CMD52 (for SDIO) when the DATA lines are busy during a data transfer. These commands can be issued when Command Inhibit (CMD) is set to zero. Other commands shall be

issued when Command Inhibit (DATA) is set to zero. Possible changes to the SD Physical Specification may add other commands to this list in the future.

- Note: the reset value of Present State Register depend on testbench connectivity.

Address: Base address + 24h offset

**uSDHCx\_PRES\_STATE field descriptions**

Field	Description
31–24 DLSL[7:0]	<p>DATA[7:0] Line Signal Level</p> <p>This status is used to check the DATA line level to recover from errors, and for debugging. This is especially useful in detecting the busy signal level from DATA0. The reset value is affected by the external pull-up / pull-down resistors. By default, the read value of this bit field after reset is 8'b11110111, when DATA3 is pulled down and the other lines are pulled up.</p> <p>DATA7 Data 7 line signal level                      DATA6 Data 6 line signal level                      DATA5 Data 5 line signal level                      DATA4 Data 4 line signal level                      DATA3 Data 3 line signal level</p>

Table continues on the next page...

## uSDHCx\_PRES\_STATE field descriptions (continued)

Field	Description
	DATA2 Data 2 line signal level DATA1 Data 1 line signal level DATA0 Data 0 line signal level
23 CLSL	CMD Line Signal Level  This status is used to check the CMD line level to recover from errors, and for debugging. The reset value is affected by the external pull-up / pull-down resistor, by default, the read value of this bit after reset is 1'b1, when the command line is pulled up.
22–20 Reserved	This read-only field is reserved and always has the value 0.
19 WPSPL	Write Protect Switch Pin Level  The Write Protect Switch is supported for memory and combo cards. This bit reflects the inverted value of the WP pin of the card socket. A software reset does not affect this bit. The reset value is effected by the external write protect switch. If the WP pin is not used, it should be tied low, so that the reset value of this bit is high and write is enabled.  1 Write enabled (WP = 0) 0 Write protected (WP = 1)
18 CDPL	Card Detect Pin Level  This bit reflects the inverse value of the CD_B pin for the card socket. Debouncing is not performed on this bit. This bit may be valid, but is not guaranteed, because of propagation delay. Use of this bit is limited to testing since it must be debounced by software. A software reset does not effect this bit. A write to the Force Event Register does not effect this bit. The reset value is effected by the external card detection pin. This bit shows the value on the CD_B pin (i.e. when a card is inserted in the socket, it is 0 on the CD_B input, and consequently the CDPL reads 1.)  1 Card present (CD_B = 0) 0 No card present (CD_B = 1)
17 Reserved	This read-only field is reserved and always has the value 0.
16 CINST	Card Inserted  This bit indicates whether a card has been inserted. The uSDHC debounces this signal so that the Host Driver will not need to wait for it to stabilize. Changing from a 0 to 1 generates a Card Insertion interrupt in the Interrupt Status register. Changing from a 1 to 0 generates a Card Removal interrupt in the Interrupt Status register. A write to the Force Event Register does not effect this bit.  The Software Reset For All in the System Control register does not effect this bit. A software reset does not effect this bit.  1 Card Inserted 0 Power on Reset or No Card
15 TSCD	Tape Select Change Done  This bit indicates the dealy setting is effective after write CLK_TUNE_CTRL_STATUS register.  1 Delay cell select change is finished. 0 Delay cell select change is not finished.
14–13 Reserved	This read-only field is reserved and always has the value 0.

*Table continues on the next page...*

## uSDHCx\_PRES\_STATE field descriptions (continued)

Field	Description
12 RTR	<p>Re-Tuning Request (only for SD3.0 SDR104 mode)</p> <p>Host Controller may request Host Driver to execute re-tuning sequence by setting this bit when the data window is shifted by temperature drift and a tuned sampling point does not have a good margin to receive correct data.</p> <p>This bit is cleared when a command is issued with setting Execute Tuning bit in MIXER_CTRL register.</p> <p>Changing of this bit from 0 to 1 generates Re-Tuning Event. Refer to Interrupt status registers for more detail.</p> <p>This bit isn't set to 1 if Sampling Clock Select in the MIXER_CTRL register is set to 0 (using fixed sampling clock).</p> <p>1 Sampling clock needs re-tuning 0 Fixed or well tuned sampling clock</p>
11 BREN	<p>Buffer Read Enable</p> <p>This status bit is used for non-DMA read transfers. The uSDHC implements an internal buffer to transfer data efficiently. This read only flag indicates that valid data exists in the host side buffer. If this bit is high, valid data greater than the watermark level exist in the buffer. A change of this bit from 1 to 0 occurs when some reads from the buffer(read DATPORT (Base + 0x20)) are made and the buffer hasn't valid data greater than the watermark level. A change of this bit from 0 to 1 occurs when there is enough valid data ready in the buffer and the Buffer Read Ready interrupt has been generated and enabled.</p> <p>1 Read enable 0 Read disable</p>
10 BWEN	<p>Buffer Write Enable</p> <p>This status bit is used for non-DMA write transfers. The uSDHC implements an internal buffer to transfer data efficiently. This read only flag indicates if space is available for write data. If this bit is 1, valid data greater than the watermark level can be written to the buffer. A change of this bit from 1 to 0 occurs when some writes to the buffer(write DATPORT(Base + 0x20)) are made and the buffer hasn't valid space greater than the watermark level. A change of this bit from 0 to 1 occurs when the buffer can hold valid data greater than the write watermark level and the Buffer Write Ready interrupt is generated and enabled.</p> <p>1 Write enable 0 Write disable</p>
9 RTA	<p>Read Transfer Active</p> <p>This status bit is used for detecting completion of a read transfer.</p> <p>This bit is set for either of the following conditions:</p> <ul style="list-style-type: none"> <li>• After the end bit of the read command.</li> <li>• When writing a 1 to the Continue Request bit in the Protocol Control register to restart a read transfer.</li> </ul> <p>A Transfer Complete interrupt is generated when this bit changes to 0. This bit is cleared for either of the following conditions:</p> <ul style="list-style-type: none"> <li>• When the last data block as specified by block length is transferred to the System, i.e. all data are read away from uSDHC internal buffer.</li> <li>• When all valid data blocks have been transferred from uSDHC internal buffer to the System and no current block transfers are being sent as a result of the Stop At Block Gap Request being set to 1.</li> </ul> <p>1 Transferring data 0 No valid data</p>

Table continues on the next page...

## uSDHCx\_PRES\_STATE field descriptions (continued)

Field	Description
8 WTA	<p>Write Transfer Active</p> <p>This status bit indicates a write transfer is active. If this bit is 0, it means no valid write data exists in the uSDHC.</p> <p>This bit is set in either of the following cases:</p> <ul style="list-style-type: none"> <li>• After the end bit of the write command.</li> <li>• When writing 1 to the Continue Request bit in the Protocol Control register to restart a write transfer.</li> </ul> <p>This bit is cleared in either of the following cases:</p> <ul style="list-style-type: none"> <li>• After getting the CRC status of the last data block as specified by the transfer count (Single and Multiple).</li> <li>• After getting the CRC status of any block where data transmission is about to be stopped by a Stop At Block Gap Request.</li> </ul> <p>During a write transaction, a Block Gap Event interrupt is generated when this bit is changed to 0, as result of the Stop At Block Gap Request being set. This status is useful for the Host Driver in determining when to issue commands during Write Busy state.</p> <p>1 Transferring data 0 No valid data</p>
7 SDOFF	<p>SD Clock Gated Off Internally</p> <p>This status bit indicates that the SD Clock is internally gated off, because of buffer over / under-run or read pause without read wait assertion, or the driver set FRC_SDCLK_ON bit is 0 to stop the SD clock in idle status. Set IPG_PERCLK_SOFT_EN and CARD_CLK_SOFT_EN to 0 also gate off SD clock. This bit is for the Host Driver to debug data transaction on the SD bus.</p> <p>1 SD Clock is gated off. 0 SD Clock is active.</p>
6 PEROFF	<p>IPG_PERCLK Gated Off Internally</p> <p>This status bit indicates that the IPG_PERCLK is internally gated off. This bit is for the Host Driver to debug transaction on the SD bus. When IPG_CLK_SOFT_EN is cleared, IPG_PERCLK will be gated off, otherwise IPG_PERCLK will be always active.</p> <p>1 IPG_PERCLK is gated off. 0 IPG_PERCLK is active.</p>
5 HCKOFF	<p>HCLK Gated Off Internally</p> <p>This status bit indicates that the HCLK is internally gated off. This bit is for the Host Driver to debug during a data transfer.</p> <p>1 HCLK is gated off. 0 HCLK is active.</p>
4 IPGOFF	<p>IPG_CLK Gated Off Internally</p> <p>This status bit indicates that the ipg_clk is internally gated off. This bit is for the Host Driver to debug.</p> <p>1 IPG_CLK is gated off. 0 IPG_CLK is active.</p>
3 SDSTB	<p>SD Clock Stable</p>

Table continues on the next page...

## uSDHCx\_PRES\_STATE field descriptions (continued)

Field	Description
	<p>This status bit indicates that the internal card clock is stable. This bit is for the Host Driver to poll clock status when changing the clock frequency. It is recommended to clear FRC_SDCLK_ON bit in System Control register to remove glitches on the card clock when the frequency is changing.</p> <p><i>Before changing clock divisor value(SDCLKFS or DVS), Host Driver should make sure the SDSTB bit is high.</i></p> <p>1 Clock is stable. 0 Clock is changing frequency and not stable.</p>
2 DLA	<p>Data Line Active</p> <p>This status bit indicates whether one of the DATA lines on the SD Bus is in use.</p> <p>In the case of read transactions:</p> <p>This status indicates if a read transfer is executing on the SD Bus. Changes in this value from 1 to 0, between data blocks, generates a Block Gap Event interrupt in the Interrupt Status register.</p> <p>This bit will be set in either of the following cases:</p> <ul style="list-style-type: none"> <li>• After the end bit of the read command.</li> <li>• When writing a 1 to the Continue Request bit in the Protocol Control register to restart a read transfer.</li> </ul> <p>This bit will be cleared in either of the following cases:</p> <p>(1) When the end bit of the last data block is sent from the SD Bus to the uSDHC. (2) When the Read Wait state is stopped by a Suspend command and the DATA2 line is released.</p> <p>The uSDHC will wait at the next block gap by driving Read Wait at the start of the interrupt cycle. If the Read Wait signal is already driven (data buffer cannot receive data), the uSDHC can wait for a current block gap by continuing to drive the Read Wait signal. It is necessary to support Read Wait in order to use the suspend / resume function. This bit will remain 1 during Read Wait.</p> <p>In the case of write transactions:</p> <p>This status indicates that a write transfer is executing on the SD Bus. Changes in this value from 1 to 0 generate a Transfer Complete interrupt in the Interrupt Status register.</p> <p>This bit will be set in either of the following cases:</p> <ul style="list-style-type: none"> <li>• After the end bit of the write command.</li> <li>• When writing to 1 to the Continue Request bit in the Protocol Control register to continue a write transfer.</li> </ul> <p>This bit will be cleared in either of the following cases:</p> <ul style="list-style-type: none"> <li>• When the SD card releases Write Busy of the last data block, the uSDHC will also detect if the output is not busy. If the SD card does not drive the busy signal after the CRC status is received, the uSDHC shall assume the card drive "Not Busy".</li> <li>• When the SD card releases write busy, prior to waiting for write transfer, and as a result of a Stop At Block Gap Request.</li> </ul> <p>In the case of command with busy pending:</p> <p>This status indicates that a busy state follows the command and the data line is in use. This bit will be cleared when the DATA0 line is released.</p> <p>1 DATA Line Active 0 DATA Line Inactive</p>

Table continues on the next page...

**uSDHCx\_PRES\_STATE field descriptions (continued)**

Field	Description
1 CDIHB	<p>Command Inhibit (DATA)</p> <p>This status bit is generated if either the DAT Line Active or the Read Transfer Active is set to 1. If this bit is 0, it indicates that the uSDHC can issue the next SD / MMC Command. Commands with a busy signal belong to Command Inhibit (DATA) (for example. R1b, R5b type). Changing from 1 to 0 generates a Transfer Complete interrupt in the Interrupt Status register.</p> <p><b>NOTE:</b> The SD Host Driver can save registers for a suspend transaction after this bit has changed from 1 to 0.</p> <p>1 Cannot issue command which uses the DATA line 0 Can issue command which uses the DATA line</p>
0 CIHB	<p>Command Inhibit (CMD)</p> <p>If this status bit is 0, it indicates that the CMD line is not in use and the uSDHC can issue a SD / MMC Command using the CMD line.</p> <p>This bit is set also immediately after the Transfer Type register is written. This bit is cleared when the command response is received. Even if the Command Inhibit (DATA) is set to 1, Commands using only the CMD line can be issued if this bit is 0. Changing from 1 to 0 generates a Command Complete interrupt in the Interrupt Status register. If the uSDHC cannot issue the command because of a command conflict error (Refer to Command CRC Error) or because of a Command Not Issued By Auto CMD12 Error, this bit will remain 1 and the Command Complete is not set. The Status of issuing an Auto CMD12 does not show on this bit.</p> <p>1 Cannot issue command 0 Can issue command using only CMD line</p>

**10.3.8.11 Protocol Control (uSDHCx\_PROT\_CTRL)**

There are three cases to restart the transfer after stop at the block gap. Which case is appropriate depends on whether the uSDHC issues a Suspend command or the SD card accepts the Suspend command.

1. If the Host Driver does not issue a Suspend command, the Continue Request shall be used to restart the transfer.
2. If the Host Driver issues a Suspend command and the SD card accepts it, a Resume command shall be used to restart the transfer.
3. If the Host Driver issues a Suspend command and the SD card does not accept it, the Continue Request shall be used to restart the transfer.

Any time Stop At Block Gap Request stops the data transfer, the Host Driver shall wait for a Transfer Complete (in the Interrupt Status register), before attempting to restart the transfer. When restarting the data transfer by Continue Request, the Host Driver shall clear the Stop At Block Gap Request before or simultaneously.

Address: Base address + 28h offset

**uSDHCx\_PROT\_CTRL field descriptions**

Field	Description
31 -	Reserved. Always write as 0
30 NON_EXACT_	Current block read is non-exact block read. It is only used for SDIO.
BLK_RD	1 The block read is non-exact block read. Host driver needs to issue abort command to terminate this multi-block read. 0 The block read is exact block read. Host driver doesn't need to issue abort command to terminate this multi-block read.
29-27 BURST_LEN_EN	BURST length enable for INCR, INCR4 / INCR8 / INCR16, INCR4-WRAP / INCR8-WRAP / INCR16-WRAP  This is used to enable / disable the burst length for the external AHB2AXI bridge. It is useful especially for INCR transfer because without burst length indicator, the AHB2AXI bridge does not know the burst length in advance. Without burst length indicator, AHB INCR transfers can only be converted to SINGLES on the AXI side.  xx1 Burst length is enabled for INCR x1x Burst length is enabled for INCR4 / INCR8 / INCR16 1xx Burst length is enabled for INCR4-WRAP / INCR8-WRAP / INCR16-WRAP
26 WECRM	Wakeup Event Enable On SD Card Removal  This bit enables a wakeup event, via a Card Removal, in the Interrupt Status register. FN_WUS (Wake Up Support) in CIS does not effect this bit. When this bit is set, the Card Removal Status and the uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active in order to assert the Card Removal Status and the uSDHC interrupt.  1 Enable 0 Disable
25 WECINS	Wakeup Event Enable On SD Card Insertion  This bit enables a wakeup event, via a Card Insertion, in the Interrupt Status register. FN_WUS (Wake Up Support) in CIS does not effect this bit. When this bit is set, the Card Insertion Status and the uSDHC

*Table continues on the next page...*

## uSDHCx\_PROT\_CTRL field descriptions (continued)

Field	Description
	<p>interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active in order to assert the Card Insertion Status and the uSDHC interrupt.</p> <p>1 Enable 0 Disable</p>
24 WECINT	<p>Wakeup Event Enable On Card Interrupt</p> <p>This bit enables a wakeup event, via a Card Interrupt, in the Interrupt Status register. This bit can be set to 1 if FN_WUS (Wake Up Support) in CIS is set to 1. When this bit is set, the Card Interrupt Status and the uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active in order to assert the Card Interrupt Status and the uSDHC interrupt.</p> <p>1 Enable 0 Disable</p>
23–21 -	Reserved. Always write as 3'b100
20 RD_DONE_NO_8CLK	<p><i>Read done no 8 clock:</i></p> <p><i>According to the SD/MMC spec, for read data transaction, 8 clocks are needed after the end bit of the last data block. So, by default(RD_DONE_NO_8CLK=0), 8 clocks will be active after the end bit of the last read data transaction.</i></p> <p><i>However, this 8 clocks should not be active if user wants to use stop at block gap(include the auto stop at block gap in boot mode) feature for read and the RWCTL bit(bit18) is not enabled. In this case, software should set RD_DONE_NO_8CLK to avoid this 8 clocks. Otherwise, the device may send extra data to uSDHC while uSDHC ignores these data.</i></p> <p><i>In a summary, this bit should be set only if the use case needs to use stop at block gap feature while the device can't support the read wait feature.</i></p>
19 IABG	<p>Interrupt At Block Gap</p> <p>This bit is valid only in 4-bit mode, of the SDIO card, and selects a sample point in the interrupt cycle. Setting to 1 enables interrupt detection at the block gap for a multiple block transfer. Setting to 0 disables interrupt detection during a multiple block transfer. If the SDIO card cannot signal an interrupt during a multiple block transfer, this bit should be set to 0 to avoid an inadvertent interrupt. When the Host Driver detects an SDIO card insertion, it shall set this bit according to the CCCR of the card.</p> <p>1 Enabled 0 Disabled</p>
18 RWCTL	<p>Read Wait Control</p> <p>The read wait function is optional for SDIO cards. If the card supports read wait, set this bit to enable use of the read wait protocol to stop read data using the DATA2 line. Otherwise the uSDHC has to stop the SD Clock to hold read data, which restricts commands generation. When the Host Driver detects an SDIO card insertion, it shall set this bit according to the CCCR of the card. If the card does not support read wait, this bit shall never be set to 1, otherwise DATA line conflicts may occur. If this bit is set to 0, stop at block gap during read operation is also supported, but the uSDHC will stop the SD Clock to pause reading operation.</p> <p>1 Enable Read Wait Control, and assert Read Wait without stopping SD Clock at block gap when SABGREQ bit is set 0 Disable Read Wait Control, and stop SD Clock at block gap when SABGREQ bit is set</p>
17 CREQ	Continue Request

Table continues on the next page...

### uSDHCx\_PROT\_CTRL field descriptions (continued)

Field	Description
	<p>This bit is used to restart a transaction which was stopped using the Stop At Block Gap Request. When a Suspend operation is not accepted by the card, it is also by setting this bit to restart the paused transfer. To cancel stop at the block gap, set Stop At Block Gap Request to 0 and set this bit to 1 to restart the transfer.</p> <p>The uSDHC automatically clears this bit, therefore it is not necessary for the Host Driver to set this bit to 0. If both Stop At Block Gap Request and this bit are 1, the continue request is ignored.</p> <p>1 Restart 0 No effect</p>
16 SABGREQ	<p>Stop At Block Gap Request</p> <p>This bit is used to stop executing a transaction at the next block gap for both DMA and non-DMA transfers. Until the Transfer Complete is set to 1, indicating a transfer completion, the Host Driver shall leave this bit set to 1. Clearing both the Stop At Block Gap Request and Continue Request does not cause the transaction to restart. Read Wait is used to stop the read transaction at the block gap. The uSDHC will honor the Stop At Block Gap Request for write transfers, but for read transfers it requires that the SDIO card support Read Wait. Therefore, the Host Driver shall not set this bit during read transfers unless the SDIO card supports Read Wait and has set the Read Wait Control to 1, otherwise the uSDHC will stop the SD bus clock to pause the read operation during block gap. In the case of write transfers in which the Host Driver writes data to the Data Port register, the Host Driver shall set this bit after all block data is written. If this bit is set to 1, the Host Driver shall not write data to the Data Port register after a block is sent. Once this bit is set, the Host Driver shall not clear this bit before the Transfer Complete bit in Interrupt Status Register is set, otherwise the uSDHCs behavior is undefined.</p> <p>This bit effects Read Transfer Active, Write Transfer Active, DATA Line Active and Command Inhibit (DATA) in the Present State register.</p> <p>1 Stop 0 Transfer</p>
15–10 Reserved	This read-only field is reserved and always has the value 0.
9–8 DMASEL	<p>DMA Select</p> <p>This field is valid while DMA (SDMA or ADMA) is enabled and selects the DMA operation.</p> <p>00 No DMA or Simple DMA is selected 01 ADMA1 is selected 10 ADMA2 is selected 11 reserved</p>
7 CDSS	<p>Card Detect Signal Selection</p> <p>This bit selects the source for the card detection.</p> <p>1 Card Detection Test Level is selected (for test purpose). 0 Card Detection Level is selected (for normal purpose).</p>
6 CDTL	<p>Card Detect Test Level</p> <p>This bit is enabled while the Card Detection Signal Selection is set to 1 and it indicates card insertion.</p> <p>1 Card Detect Test Level is 1, card inserted 0 Card Detect Test Level is 0, no card inserted</p>
5–4 EMODE	Endian Mode

*Table continues on the next page...*

## uSDHCx\_PROT\_CTRL field descriptions (continued)

Field	Description
	<p>The uSDHC supports all three endian modes in data transfer. Refer to <a href="#">Data Buffer</a> for more details.</p> <p>00 Big Endian Mode  01 Half Word Big Endian Mode  10 Little Endian Mode  11 Reserved</p>
3 D3CD	<p>DATA3 as Card Detection Pin</p> <p>If this bit is set, DATA3 should be pulled down to act as a card detection pin. Be cautious when using this feature, because DATA3 is also a chip-select for the SPI mode. A pull-down on this pin and CMD0 may set the card into the SPI mode, which the uSDHC does not support.</p> <p>1 DATA3 as Card Detection Pin  0 DATA3 does not monitor Card Insertion</p>
2-1 DTW[1:0]	<p>Data Transfer Width</p> <p>This bit selects the data width of the SD bus for a data transfer. The Host Driver shall set it to match the data width of the card. Possible Data transfer Width is 1-bit, 4-bits or 8-bits.</p> <p>10 8-bit mode  01 4-bit mode  00 1-bit mode  11 Reserved</p>
0 LCTL	<p>LED Control</p> <p>This bit, fully controlled by the Host Driver, is used to caution the user not to remove the card while the card is being accessed. If the software is going to issue multiple SD commands, this bit can be set during all these transactions. It is not necessary to change for each transaction. When the software issues multiple SD commands, setting the bit once before the first command is sufficient: it is not necessary to reset the bit between commands.</p> <p>1 LED on  0 LED off</p>

### 10.3.8.12 System Control (uSDHCx\_SYS\_CTRL)

Address: Base address + 2Ch offset

**uSDHCx\_SYS\_CTRL field descriptions**

Field	Description
31–29 Reserved	This read-only field is reserved and always has the value 0.
28 RSTT	Reset Tuning When set this bit to 1, it will reset tuning circuit. After tuning circuits are reset, bit value is 0. Clearing execute_tuning bit in AUTOCMD12_ERR_STATUS will also set this bit to 1 to reset tuning circuit
27 INITA	Initialization Active When this bit is set, 80 SD-Clocks are sent to the card. After the 80 clocks are sent, this bit is self cleared. This bit is very useful during the card power-up period when 74 SD-Clocks are needed and the clock auto gating feature is enabled. Writing 1 to this bit when this bit is already 1 has no effect. Writing 0 to this bit at any time has no effect. When either of the CIHB and CDIHB bits in the Present State Register are set, writing 1 to this bit is ignored (i.e. when command line or data lines are active, write to this bit is not allowed). On the otherhand, when this bit is set, i.e., during intialization active period, it is allowed to issue command, and the command bit stream will appear on the CMD pad after all 80 clock cycles are done. So when this command ends, the driver can make sure the 80 clock cycles are sent out. This is very useful when the driver needs send 80 cycles to the card and does not want to wait till this bit is self cleared.
26 RSTD	Software Reset For DATA Line

*Table continues on the next page...*

## uSDHCx\_SYS\_CTRL field descriptions (continued)

Field	Description
	<p>Only part of the data circuit is reset. DMA circuit is also reset. After this bit is set, SW waits for self-clear.</p> <p>The following registers and bits are cleared by this bit:</p> <ul style="list-style-type: none"> <li>• Data Port register</li> <li>• Buffer is cleared and initialized.</li> <li>• Present State register</li> <li>• Buffer Read Enable</li> <li>• Buffer Write Enable</li> <li>• Read Transfer Active</li> <li>• Write Transfer Active</li> <li>• DATA Line Active</li> <li>• Command Inhibit (DATA) Protocol Control register</li> <li>• Continue Request</li> <li>• Stop At Block Gap Request Interrupt Status register</li> <li>• Buffer Read Ready</li> <li>• Buffer Write Ready</li> <li>• DMA Interrupt</li> <li>• Block Gap Event</li> <li>• Transfer Complete</li> </ul> <p><b>NOTE:</b> When reset, SW must make sure there is no incomplete data transferring. If there is data transfer going on, SW need wait TC or DC uSDHC_INT_STATUS register is set.</p> <p>1 Reset 0 No Reset</p>
25 RSTC	<p>Software Reset For CMD Line</p> <p>Only part of the command circuit is reset. After this bit is set, SW waits for self-clear.</p> <p>The following registers and bits are cleared by this bit:</p> <ul style="list-style-type: none"> <li>• Present State register Command Inhibit (CMD)</li> <li>• Interrupt Status register Command Complete</li> </ul> <p>1 Reset 0 No Reset</p>
24 RSTA	<p>Software Reset For ALL</p> <p>This reset effects the entire Host Controller except for the card detection circuit. Register bits of type ROC, RW, RW1C, RWAC are cleared. During its initialization, the Host Driver shall set this bit to 1 to reset the uSDHC. The uSDHC shall reset this bit to 0 when the capabilities registers are valid and the Host Driver can read them. Additional use of Software Reset For All does not affect the value of the Capabilities registers. After this bit is set, it is recommended that the Host Driver reset the external card and re-initialize it. After this bit is set, SW should wait for self-clear.</p> <p>In tuning process, after every CMD19 is finished, this bit will be set to retest the uSDHC.</p> <p><b>NOTE:</b> When reset, SW must make sure there is no incomplete data transferring. If there is data transfer going on, SW need wait TC or DC uSDHC_INT_STATUS register is set.</p> <p>1 Reset 0 No Reset</p>
23 IPP_RST_N	<p>This register's value will be output to CARD from pad directly for hardware reset of the card if the card supports this feature.</p>
22 -	Reserved

## uSDHCx\_SYS\_CTRL field descriptions (continued)

Field	Description
21–20 Reserved	This read-only field is reserved and always has the value 0.
19–16 DTCOV	<p>Data Timeout Counter Value</p> <p>This value determines the interval by which DAT line timeouts are detected. Refer to the Data Timeout Error bit in the Interrupt Status register for information on factors that dictate time-out generation. Time-out clock frequency will be generated by dividing the base clock SDCLK value by this value.</p> <p>The Host Driver can clear the Data Timeout Error Status Enable (in the Interrupt Status Enable register) to prevent inadvertent time-out events.</p> <p>1111 SDCLK x 2<sup>28</sup>  1110 SDCLK x 2<sup>27</sup>  0001 SDCLK x 2<sup>14</sup>  0000 SDCLK x 2<sup>13</sup></p>
15–8 SDCLKFS	<p>SDCLK Frequency Select</p> <p>This register is used to select the frequency of the SDCLK pin. The frequency is not programmed directly, rather this register holds the prescaler (this register) and divisor (next register) of the Base Clock Frequency register.</p> <p><i>In Single Data Rate mode(DDR_EN bit of MIXERCTRL is '0')</i></p> <p>Only the following settings are allowed:</p> <p>80h) Base clock divided by 256  40h) Base clock divided by 128  20h) Base clock divided by 64  10h) Base clock divided by 32  08h) Base clock divided by 16  04h) Base clock divided by 8  02h) Base clock divided by 4  01h) Base clock divided by 2  00h) Base clock divided by 1</p> <p><i>While in Dual Data Rate mode(DDR_EN bit of MIXERCTRL is '1')</i></p> <p>Only the following settings are allowed:</p> <p>80h) Base clock divided by 512  40h) Base clock divided by 256  20h) Base clock divided by 128  10h) Base clock divided by 64  08h) Base clock divided by 32  04h) Base clock divided by 16  02h) Base clock divided by 8  01h) Base clock divided by 4  00h) Base clock divided by 2</p> <p><i>When S/W changes the DDR_EN bit, SDCLKFS may need to be changed also!</i></p>

Table continues on the next page...

## uSDHCx\_SYS\_CTRL field descriptions (continued)

Field	Description
	<p>In Single Data Rate mode, setting 00h bypasses the frequency prescaler of the SD Clock.</p> <p>Multiple bits must not be set, or the behavior of this prescaler is undefined. The two default divider values can be calculated by the frequency of ipg_perclk and the following Divisor bits.</p> <p>The frequency of SDCLK is set by the following formula:</p> <p>Clock Frequency = (Base Clock) / (prescaler x divisor)</p> <p>For example, in Single Data Rate mode, if the Base Clock Frequency is 96 MHz, and the target frequency is 25 MHz, then choosing the prescaler value of 01h and divisor value of 1h will yield 24 MHz, which is the nearest frequency less than or equal to the target. Similarly, to approach a clock value of 400 kHz, the prescaler value of 08h and divisor value of eh yields the exact clock value of 400 kHz.</p> <p>The reset value of this bit field is 80h, so if the input Base Clock (ipg_perclk) is about 96 MHz, the default SD Clock after reset is 375 kHz.</p> <p>According to the SD Physical Specification Version 1.1 and the SDIO Card Specification Version 1.2, the maximum SD Clock frequency is 50 MHz and shall never exceed this limit.</p> <p><i>Before changing clock divisor value(SDCLKFS or DVS), Host Driver should make sure the SDSTB bit is high.</i></p> <p><i>If setting SDCLKFS and DVS can generate same clock frequency,(For example, in SDR mode, SDCLKFS = 01h is same as DVS = 01h.) SDCLKFS is highly recommended.</i></p>
7-4 DVS[3:0]	<p>Divisor</p> <p>This register is used to provide a more exact divisor to generate the desired SD clock frequency. Note the divider can even support odd divisors without deterioration of duty cycle.</p> <p><i>Before changing clock divisor value(SDCLKFS or DVS), Host Driver should make sure the SDSTB bit is high.</i></p> <p>The setting are as following:</p> <p>0000 Divide-by-1 0001 Divide-by-2 ..... 1110 Divide-by-15 1111 Divide-by-16</p>
-	Reserved. Always write as 1.

### 10.3.8.13 Interrupt Status (uSDHCx\_INT\_STATUS)

An interrupt is generated when the Normal Interrupt Signal Enable is enabled and at least one of the status bits is set to 1. For all bits, writing 1 to a bit clears it; writing to 0 keeps the bit unchanged. More than one status can be cleared with a single register write. For Card Interrupt, before writing 1 to clear, it is required that the card stops asserting the interrupt, meaning that when the Card Driver services the interrupt condition, otherwise the CINT bit will be asserted again.

The table below shows the relationship between the Command Timeout Error and the Command Complete.

**Table 10-47. uSDHC Status for Command Timeout Error/Command Complete Bit Combinations**

Command Complete	Command Timeout Error	Meaning of the Status
0	0	X
X	1	Response not received within 64 SDCLK cycles
1	0	Response received

The table below shows the relationship between the Transfer Complete and the Data Timeout Error.

**Table 10-48. uSDHC Status for Data Timeout Error/Transfer Complete Bit Combinations**

Transfer Complete	Data Timeout Error	Meaning of the Status
0	0	X
0	1	Timeout occurred during transfer
1	X	Data Transfer Complete

The table below shows the relationship between the Command CRC Error and Command Timeout Error.

**Table 10-49. uSDHC Status for Command CRC Error/Command Timeout Error Bit Combinations**

Command Complete	Command Timeout Error	Meaning of the Status
0	0	No error
0	1	Response Timeout Error
1	0	Response CRC Error
1	1	CMD line conflict

### uSDHCx\_INT\_STATUS field descriptions

Field	Description
31–29 Reserved	This read-only field is reserved and always has the value 0.
28 DMAE	<p>DMA Error</p> <p>Occurs when an Internal DMA transfer has failed. This bit is set to 1, when some error occurs in the data transfer. This error can be caused by either Simple DMA or ADMA, depending on which DMA is in use. The value in DMA System Address register is the next fetch address where the error occurs. Since any error corrupts the whole data block, the Host Driver shall re-start the transfer from the corrupted block boundary. The address of the block boundary can be calculated either from the current DS_ADDR value or from the remaining number of blocks and the block size.</p> <p>1 Error 0 No Error</p>
27 Reserved	This read-only field is reserved and always has the value 0.
26 TNE	<p>Tuning Error: (only for SD3.0 SDR104 mode)</p> <p>This bit is set when an unrecoverable error is detected in a tuning circuit. By detecting Tuning Error, Host Driver needs to abort a command executing and perform tuning.</p>
25 Reserved	This read-only field is reserved and always has the value 0.
24 AC12E	<p>Auto CMD12 Error</p> <p>Occurs when detecting that one of the bits in the Auto CMD12 Error Status register has changed from 0 to 1. This bit is set to 1, not only when the errors in Auto CMD12 occur, but also when the Auto CMD12 is not executed due to the previous command error.</p> <p>1 Error 0 No Error</p>
23 Reserved	This read-only field is reserved and always has the value 0.
22 DEBE	<p>Data End Bit Error</p> <p>Occurs either when detecting 0 at the end bit position of read data, which uses the DATA line, or at the end bit position of the CRC.</p> <p>This bit will be not asserted in tuning process.</p> <p>1 Error 0 No Error</p>

## uSDHCx\_INT\_STATUS field descriptions (continued)

Field	Description
21 DCE	<p>Data CRC Error</p> <p>Occurs when detecting a CRC error when transferring read data, which uses the DATA line, or when detecting the Write CRC status having a value other than 010.</p> <p>This bit will be not asserted in tuning process.</p> <p>1 Error 0 No Error</p>
20 DIOE	<p>Data Timeout Error</p> <p>Occurs when detecting one of following time-out conditions.</p> <ul style="list-style-type: none"> <li>• Busy time-out for R1b, R5b type</li> <li>• Busy time-out after Write CRC status</li> <li>• Read Data time-out.</li> </ul> <p>This bit will be not asserted in tuning process.</p> <p>1 Time out 0 No Error</p>
19 CIE	<p>Command Index Error</p> <p>Occurs if a Command Index error occurs in the command response.</p> <p>This bit will be not asserted in tuning process.</p> <p>1 Error 0 No Error</p>
18 CEBE	<p>Command End Bit Error</p> <p>Occurs when detecting that the end bit of a command response is 0.</p> <p>This bit will be not asserted in tuning process.</p> <p>1 End Bit Error Generated 0 No Error</p>
17 CCE	<p>Command CRC Error</p> <p>Command CRC Error is generated in two cases.</p> <ul style="list-style-type: none"> <li>• If a response is returned and the Command Timeout Error is set to 0 (indicating no time-out), this bit is set when detecting a CRC error in the command response.</li> <li>• The uSDHC detects a CMD line conflict by monitoring the CMD line when a command is issued. If the uSDHC drives the CMD line to 1, but detects 0 on the CMD line at the next SDCLK edge, then the uSDHC shall abort the command (Stop driving CMD line) and set this bit to 1. The Command Timeout Error shall also be set to 1 to distinguish CMD line conflict.</li> </ul> <p>This bit will be not asserted in tuning process.</p> <p>1 CRC Error Generated. 0 No Error</p>
16 CTOE	<p>Command Timeout Error</p> <p>Occurs only if no response is returned within 64 SDCLK cycles from the end bit of the command. If the uSDHC detects a CMD line conflict, in which case a Command CRC Error shall also be set (as shown in <a href="#">Interrupt Status (uSDHC_INT_STATUS)</a> ), this bit shall be set without waiting for 64 SDCLK cycles. This is because the command will be aborted by the uSDHC.</p>

*Table continues on the next page...*

## uSDHCx\_INT\_STATUS field descriptions (continued)

Field	Description
	This bit will be not asserted in tuning process. 1 Time out 0 No Error
15 Reserved	This read-only field is reserved and always has the value 0.
14 TP	Tuning Pass:(only for SD3.0 SDR104 mode) Current CMD19 transfer is done successfully. That is, current sampling point is correct.
13 Reserved	This read-only field is reserved and always has the value 0.
12 RTE	Re-Tuning Event: (only for SD3.0 SDR104 mode) This status is set if Re-Tuning Request in the Present State register changes from 0 to 1. Host Controller requests Host Driver to perform re-tuning for next data transfer. Current data transfer (not large block count) can be completed without re-tuning. 1 Re-Tuning should be performed 0 Re-Tuning is not required
11–9 Reserved	This read-only field is reserved and always has the value 0.
8 CINT	Card Interrupt This status bit is set when an interrupt signal is detected from the external card. In 1-bit mode, the uSDHC will detect the Card Interrupt without the SD Clock to support wakeup. In 4-bit mode, the card interrupt signal is sampled during the interrupt cycle, so the interrupt from card can only be sampled during interrupt cycle, introducing some delay between the interrupt signal from the SDIO card and the interrupt to the Host System. Writing this bit to 1 can clear this bit, but as the interrupt source from the SDIO card does not clear, this bit is set again. In order to clear this bit, it is required to reset the interrupt source from the external card followed by a writing 1 to this bit. When this status has been set, and the Host Driver needs to service this interrupt, the Card Interrupt Signal Enable in the Interrupt Signal Enable register should be 0 to stop driving the interrupt signal to the Host System. After completion of the card interrupt service (It should reset the interrupt sources in the SDIO card and the interrupt signal may not be asserted), write 1 to clear this bit, set the Card Interrupt Signal Enable to 1, and start sampling the interrupt signal again. 1 Generate Card Interrupt 0 No Card Interrupt
7 CRM	Card Removal This status bit is set if the Card Inserted bit in the Present State register changes from 1 to 0. When the Host Driver writes this bit to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed. Because the card state may possibly be changed when the Host Driver clears this bit and the interrupt event may not be generated. When this bit is cleared, it will be set again if no card is inserted. In order to leave it cleared, clear the Card Removal Status Enable bit in Interrupt Status Enable register. 1 Card removed 0 Card state unstable or inserted
6 CINS	Card Insertion This status bit is set if the Card Inserted bit in the Present State register changes from 0 to 1. When the Host Driver writes this bit to 1 to clear this status, the status of the Card Inserted in the Present State

*Table continues on the next page...*

## uSDHCx\_INT\_STATUS field descriptions (continued)

Field	Description
	<p>register should be confirmed. Because the card state may possibly be changed when the Host Driver clears this bit and the interrupt event may not be generated. When this bit is cleared, it will be set again if a card is inserted. In order to leave it cleared, clear the Card Inserted Status Enable bit in Interrupt Status Enable register.</p> <p>1 Card inserted 0 Card state unstable or removed</p>
5 BRR	<p>Buffer Read Ready</p> <p>This status bit is set if the Buffer Read Enable bit, in the Present State register, changes from 0 to 1. Refer to the Buffer Read Enable bit in the Present State register for additional information.</p> <p>This bit indicates that cmd19 is finished in tuning process.</p> <p>1 Ready to read buffer 0 Not ready to read buffer</p>
4 BWR	<p>Buffer Write Ready</p> <p>This status bit is set if the Buffer Write Enable bit, in the Present State register, changes from 0 to 1. Refer to the Buffer Write Enable bit in the Present State register for additional information.</p> <p>1 Ready to write buffer: 0 Not ready to write buffer</p>
3 DINT	<p>DMA Interrupt</p> <p>Occurs only when the internal DMA finishes the data transfer successfully. Whenever errors occur during data transfer, this bit will not be set. Instead, the DMAE bit will be set. Either Simple DMA or ADMA finishes data transferring, this bit will be set.</p> <p>1 DMA Interrupt is generated 0 No DMA Interrupt</p>
2 BGE	<p>Block Gap Event</p> <p>If the Stop At Block Gap Request bit in the Protocol Control register is set, this bit is set when a read or write transaction is stopped at a block gap. If Stop At Block Gap Request is not set to 1, this bit is not set to 1.</p> <p>In the case of a Read Transaction: This bit is set at the falling edge of the DATA Line Active Status (When the transaction is stopped at SD Bus timing). The Read Wait must be supported in order to use this function.</p> <p>In the case of Write Transaction: This bit is set at the falling edge of Write Transfer Active Status (After getting CRC status at SD Bus timing).</p> <p>1 Transaction stopped at block gap 0 No block gap event</p>
1 TC	<p>Transfer Complete</p> <p>This bit is set when a read or write transfer is completed.</p> <p>In the case of a Read Transaction: This bit is set at the falling edge of the Read Transfer Active Status. There are two cases in which this interrupt is generated. The first is when a data transfer is completed as specified by the data length (after the last data has been read to the Host System). The second is when data has stopped at the block gap and completed the data transfer by setting the Stop At Block Gap Request bit in the Protocol Control register (after valid data has been read to the Host System).</p>

*Table continues on the next page...*

## uSDHCx\_INT\_STATUS field descriptions (continued)

Field	Description
	<p>In the case of a Write Transaction: This bit is set at the falling edge of the DATA Line Active Status. There are two cases in which this interrupt is generated. The first is when the last data is written to the SD card as specified by the data length and the busy signal is released. The second is when data transfers are stopped at the block gap, by setting the Stop At Block Gap Request bit in the Protocol Control register, and the data transfers are completed. (after valid data is written to the SD card and the busy signal released).</p> <p>In the case of a command with busy, this bit is set when busy is deasserted.</p> <p>This bit will be not asserted in tuning process.</p> <p>1 Transfer complete 0 Transfer not complete</p>
0 CC	<p>Command Complete</p> <p>This bit is set when you receive the end bit of the command response (except Auto CMD12). Refer to the Command Inhibit (CMD) in the Present State register.</p> <p>This bit will be not asserted in tuning process.</p> <p>1 Command complete 0 Command not complete</p>

## 10.3.8.14 Interrupt Status Enable (uSDHCx\_INT\_STATUS\_EN)

Setting the bits in this register to 1 enables the corresponding Interrupt Status to be set by the specified event. If any bit is cleared, the corresponding Interrupt Status bit is also cleared (i.e. when the bit in this register is cleared, the corresponding bit in Interrupt Status Register is always 0).

- Depending on IABG bit setting, uSDHC may be programmed to sample the card interrupt signal during the interrupt period and hold its value in the flip-flop. There will be some delays on the Card Interrupt, asserted from the card, to the time the Host System is informed.
- To detect a CMD line conflict, the Host Driver must set both Command Timeout Error Status Enable and Command CRC Error Status Enable to 1.

## 10.3.8.15 Interrupt Signal Enable (uSDHCx\_INT\_SIGNAL\_EN)

This register is used to select which interrupt status is indicated to the Host System as the interrupt. These status bits all share the same interrupt line. Setting any of these bits to 1 enables interrupt generation. The corresponding Status register bit will generate an interrupt when the corresponding interrupt signal enable bit is set.

### 10.3.8.16 Auto CMD12 Error Status (uSDHCx\_AUTOCMD12\_ERR\_STATUS)

When the Auto CMD12 Error Status bit in the Status register is set, the Host Driver shall check this register to identify what kind of error the Auto CMD12 / CMD 23 indicated. Auto CMD23 errors are indicated in bit 04-01. This register is valid only when the Auto CMD12 Error status bit is set.

The table below shows the relationship between the Auto CMD12 CRC Error and the Auto CMD12 Command Timeout Error.

**Table 10-50. Relationship Between Command CRC Error and Command Timeout Error for Auto CMD12**

Auto CMD12 CRC Error	Auto CMD12 Timeout Error	Type of Error
0	0	No Error
0	1	Response Timeout Error
1	0	Response CRC Error
1	1	CMD line conflict

Changes in Auto CMD12 Error Status register can be classified in three scenarios:

1. When the uSDHC is going to issue an Auto CMD12.
  - Set bit 0 to 1 if the Auto CMD12 can't be issued due to an error in the previous command
  - Set bit 0 to 0 if the Auto CMD12 is issued
2. At the end bit of an Auto CMD12 response.
  - Check errors correspond to bits 1-4.
  - Set bits 1-4 corresponding to detected errors.
  - Clear bits 1-4 corresponding to detected errors
3. Before reading the Auto CMD12 Error Status bit 7.
  - Set bit 7 to 1 if there is a command that can't be issued
  - Clear bit 7 if there is no command to issue

The timing for generating the Auto CMD12 Error and writing to the Command register are asynchronous. After that, bit 7 shall be sampled when the driver is not writing to the Command register. So it is suggested to read this register only when the AC12E bit in Interrupt Status register is set. An Auto CMD12 Error Interrupt is generated when one of the error bits (0-4) is set to 1. The Command Not Issued By Auto CMD12 Error does not generate an interrupt.

Address: Base address + 3Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

**uSDHCx\_AUTOCMD12\_ERR\_STATUS field descriptions**

Field	Description
31–24 Reserved	This read-only field is reserved and always has the value 0.
23 SMP_CLK_SEL	<p>Sample Clock Select</p> <p>When <code>std_tuning_en</code> bit is set, this bit is used to select sampling clock to receive CMD and DATA. Otherwise, this bit is reserved. This bit is set by ty tuning procedure and valid after the completion of tuning(When Execute Tuning is cleared). Setting 1 means that tuning is completed successfully and setting 0 means that tuning is failed. Writing 1 to this bit is meaningless and ignored. A tuning circuit is reset by writing to 0. This bit can be cleared with setting Execute Tuning. Once the tuning circuit is reset, it will take time to complete tuning sequence. Therefore, Host Driver should keep this bit to 1 to perform re-tuning sequence to complete re-tuning sequence in a short time. Change of this bit is not allowed while the Host controller us receiving response or a read data block.</p>

*Table continues on the next page...*

## uSDHCx\_AUTOCMD12\_ERR\_STATUS field descriptions (continued)

Field	Description
	1 Tuned clock is used to sample data 0 Fixed clock is used to sample data
22 EXECUTE_TUNING	Execute Tuning  When std_tuning_en bit is set, this bit is used to start tuning procedure. Otherwise, this bit is reserved. This bit is set to start tuning procedure and automatically cleared when tuning procedure is completed. The result of tuning is indicated to sam_clk_sel bit. Tuning procedure is aborted by writing 0.
21–8 Reserved	This read-only field is reserved and always has the value 0.
7 CNIBAC12E	Command Not Issued By Auto CMD12 Error  Setting this bit to 1 means CMD_wo_DAT is not executed due to an Auto CMD12 Error (D04-D01) in this register.  1 Not Issued 0 No error
6–5 Reserved	This read-only field is reserved and always has the value 0.
4 AC12IE	Auto CMD12 / 23 Index Error  Occurs if the Command Index error occurs in response to a command.  1 Error, the CMD index in response is not CMD12/23 0 No error
3 AC12CE	Auto CMD12 / 23 CRC Error  Occurs when detecting a CRC error in the command response.  1 CRC Error Met in Auto CMD12/23 Response 0 No CRC error
2 AC12EBE	Auto CMD12 / 23 End Bit Error  Occurs when detecting that the end bit of command response is 0 which should be 1.  1 End Bit Error Generated 0 No error
1 AC12TOE	Auto CMD12 / 23 Timeout Error  Occurs if no response is returned within 64 SDCLK cycles from the end bit of the command. If this bit is set to 1, the other error status bits (2-4) have no meaning.  1 Time out 0 No error
0 AC12NE	Auto CMD12 Not Executed  If memory multiple block data transfer is not started, due to a command error, this bit is not set because it is not necessary to issue an Auto CMD12. Setting this bit to 1 means the uSDHC cannot issue the Auto CMD12 to stop a memory multiple block data transfer due to some error. If this bit is set to 1, other error status bits (1-4) have no meaning.  1 Not executed 0 Executed

### 10.3.8.17 Host Controller Capabilities (uSDHCx\_HOST\_CTRL\_CAP)

This register provides the Host Driver with information specific to the uSDHC implementation. The value in this register is the power-on-reset value, and does not change with a software reset.

Address: Base address + 40h offset

Field	Description
31-29 Reserved	This read-only field is reserved and always has the value 0.
28-24 WR_BRST_ LEN[4:0]	Write Burst Length <sup>1</sup> The number of words the uSDHC writes in a single burst. The write burst length must be less than or equal to the write watermark level, and all bursts within a watermark level transfer will be in back-to-back mode. On reset, this field will be 8. Writing 0 to this field will result in '01000' (i.e. it is not able to clear this field).
23-16 WR_WML[7:0]	Write Watermark Level The number of words used as the watermark level (FIFO threshold) in a DMA write operation. Also the number of words as a sequence of write bursts in back-to-back mode. The maximum legal value for the write watermark level is 128.
15-13 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

## uSDHCx\_WTMK\_LVL field descriptions (continued)

Field	Description
12–8 RD_BRST_LEN[4:0]	Read Burst Length <sup>2</sup> The number of words the uSDHC reads in a single burst. The read burst length must be less than or equal to the read watermark level, and all bursts within a watermark level transfer will be in back-to-back mode. On reset, this field will be 8. Writing 0 to this field will result in '01000' (i.e. it is not able to clear this field).
RD_WML[7:0]	Read Watermark Level The number of words used as the watermark level (FIFO threshold) in a DMA read operation. Also the number of words as a sequence of read bursts in back-to-back mode. The maximum legal value for the read water mark level is 128.

1. Due to system restriction, the actual burst length may not exceed 16.

2. Due to system restriction, the actual burst length may not exceed 16.

## 10.3.8.19 Mixer Control (uSDHCx\_MIX\_CTRL)

This register is used to DMA and data transfer. To prevent data loss, The software should check if data transfer is active before writing this register. These bits are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN, and DMAEN.

Table 10-51. Transfer Type Register Setting for Various Transfer Types

Multi/Single Block Select	Block Count Enable	Block Count	Function
0	Don't Care	Don't Care	Single Transfer
1	0	Don't Care	Infinite Transfer
1	1	Positive Number	Multiple Transfer
1	1	Zero	No Data Transfer

## uSDHCx\_MIX\_CTRL field descriptions

Field	Description
31 -	Reserved. Always write as 1
30 -	Reserved. Always write as 0.
29 -	Reserved. Always write as 0.
28–27 Reserved	This read-only field is reserved and always has the value 0.
26 HS400_MODE	Enable HS400 Mode HS400 Enable
25 FBCLK_SEL	Feedback Clock Source Selection (Only used for SD3.0, SDR104 mode) 1 Feedback clock comes from the ipp_card_clk_out 0 Feedback clock comes from the loopback CLK
24 AUTO_TUNE_EN	Auto Tuning Enable (Only used for SD3.0, SDR104 mode) 1 Enable auto tuning 0 Disable auto tuning
23 SMP_CLK_SEL	When STD_TUNING_EN is 0, this bit is used to select Tuned clock or Fixed clock to sample data / cmd (Only used for SD3.0, SDR104 mode) 1 Tuned clock is used to sample data / cmd 0 Fixed clock is used to sample data / cmd
22 EXE_TUNE	Execute Tuning: (Only used for SD3.0, SDR104 mode) When STD_TUNING_EN is 0, this bit is set to 1 to indicate the Host Driver is starting tuning procedure. Tuning procedure is aborted by writing 0. 1 Execute Tuning 0 Not Tuned or Tuning Completed
21–8 Reserved	This read-only field is reserved and always has the value 0.
7 AC23EN	Auto CMD23 Enable When this bit is set to 1, the Host Controller issues a CMD23 automatically before issuing a command specified in the Command Register.
6 NIBBLE_POS	In DDR 4-bit mode nibble position indication. 0- the sequence is 'odd high nibble -> even high nibble -> odd low nibble -> even low nibble'; 1- the sequence is 'odd high nibble -> odd low nibble -> even high nibble -> even low nibble'.
5 MSBSEL	Multi / Single Block Select This bit enables multiple block DATA line data transfers. For any other commands, this bit can be set to 0. If this bit is 0, it is not necessary to set the Block Count register. (Refer to <a href="#">Command Transfer Type (uSDHC_CMD_XFR_TYP)</a> ). 1 Multiple Blocks 0 Single Block
4 DTDSEL	Data Transfer Direction Select

Table continues on the next page...

**uSDHCx\_MIX\_CTRL field descriptions (continued)**

Field	Description
	<p>This bit defines the direction of DATA line data transfers. The bit is set to 1 by the Host Driver to transfer data from the SD card to the uSDHC and is set to 0 for all other commands.</p> <p>1 Read (Card to Host) 0 Write (Host to Card)</p>
3 DDR_EN	Dual Data Rate mode selection
2 AC12EN	<p>Auto CMD12 Enable</p> <p>Multiple block transfers for memory require a CMD12 to stop the transaction. When this bit is set to 1, the uSDHC will issue a CMD12 automatically when the last block transfer has completed. The Host Driver shall not set this bit to issue commands that do not require CMD12 to stop a multiple block data transfer. In particular, secure commands defined in File Security Specification (see reference list) do not require CMD12. In single block transfer, the uSDHC will ignore this bit no matter it is set or not.</p> <p>1 Enable 0 Disable</p>
1 BCEN	<p>Block Count Enable</p> <p>This bit is used to enable the Block Count register, which is only relevant for multiple block transfers. When this bit is 0, the internal counter for block is disabled, which is useful in executing an infinite transfer.</p> <p>1 Enable 0 Disable</p>
0 DMAEN	<p>DMA Enable</p> <p>This bit enables DMA functionality. If this bit is set to 1, a DMA operation shall begin when the Host Driver sets the DPSEL bit of this register. Whether the Simple DMA or the Advanced DMA is active depends on the DMA Select field of the Protocol Control register.</p> <p>1 Enable 0 Disable</p>

**10.3.8.20 Force Event (uSDHCx\_FORCE\_EVENT)**

The Force Event Register is not a physically implemented register. Rather, it is an address at which the Interrupt Status Register can be written if the corresponding bit of the Interrupt Status Enable Register is set. This register is a write only register and writing 0 to it has no effect. Writing 1 to this register actually sets the corresponding bit of Interrupt Status Register. A read from this register always results in 0's. In order to change the corresponding status bits in the Interrupt Status Register, make sure to set IPGEN bit in System Control Register so that IPG\_CLK is always active.

Forcing a card interrupt will generate a short pulse on the DATA1 line, and the driver may treat this interrupt as a normal interrupt. The interrupt service routine may skip polling the card interrupt factor as the interrupt is self cleared.

## Ultra Secured Digital Host Controller (uSDHC)

Address: Base address + 50h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

### uSDHCx\_FORCE\_EVENT field descriptions

Field	Description
31 FEVTCINT	Force Event Card Interrupt  Writing 1 to this bit generates a short low-level pulse on the internal DATA1 line, as if a self clearing interrupt was received from the external card. If enabled, the CINT bit will be set and the interrupt service routine may treat this interrupt as a normal interrupt from the external card.
30–29 Reserved	This read-only field is reserved and always has the value 0.
28 FEVTDMAE	Force Event DMA Error  Forces the DMAE bit of Interrupt Status Register to be set.
27 Reserved	This read-only field is reserved and always has the value 0.
26 FEVTTNE	Force Tuning Error  Forces the TNE bit of Interrupt Status Register to be set.
25 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

**uSDHCx\_FORCE\_EVENT field descriptions (continued)**

<b>Field</b>	<b>Description</b>
24 FEVTAC12E	Force Event Auto Command 12 Error Forces the AC12E bit of Interrupt Status Register to be set.
23 Reserved	This read-only field is reserved and always has the value 0.
22 FEVTDEBE	Force Event Data End Bit Error Forces the DEBE bit of Interrupt Status Register to be set.
21 FEVTDCE	Force Event Data CRC Error Forces the DCE bit of Interrupt Status Register to be set.
20 FEVTDTOE	Force Event Data Time Out Error Force the DTOE bit of Interrupt Status Register to be set.
19 FEVTCIE	Force Event Command Index Error Forces the CCE bit of Interrupt Status Register to be set.
18 FEVTCBE	Force Event Command End Bit Error Forces the CEBE bit of Interrupt Status Register to be set.
17 FEVTCCE	Force Event Command CRC Error Forces the CCE bit of Interrupt Status Register to be set.
16 FEVCTOE	Force Event Command Time Out Error Forces the CTOE bit of Interrupt Status Register to be set.
15–8 Reserved	This read-only field is reserved and always has the value 0.
7 FEVTCNIBAC12E	Force Event Command Not Executed By Auto Command 12 Error Forces the CNIBAC12E bit in the Auto Command12 Error Status Register to be set.
6–5 Reserved	This read-only field is reserved and always has the value 0.
4 FEVTAC12IE	Force Event Auto Command 12 Index Error Forces the AC12IE bit in the Auto Command12 Error Status Register to be set.
3 FEVTAC12EBE	Force Event Auto Command 12 End Bit Error Forces the AC12EBE bit in the Auto Command12 Error Status Register to be set.
2 FEVTAC12CE	Force Event Auto Command 12 CRC Error Forces the AC12CE bit in the Auto Command12 Error Status Register to be set.
1 FEVTAC12TOE	Force Event Auto Command 12 Time Out Error Forces the AC12TOE bit in the Auto Command12 Error Status Register to be set.
0 FEVTAC12NE	Force Event Auto Command 12 Not Executed Forces the AC12NE bit in the Auto Command12 Error Status Register to be set.

### 10.3.8.21 ADMA Error Status Register (uSDHCx\_ADMA\_ERR\_STATUS)

When an ADMA Error Interrupt has occurred, the ADMA Error States field in this register holds the ADMA state and the ADMA System Address register holds the address around the error descriptor.

For recovering from this error, the Host Driver requires the ADMA state to identify the error descriptor address as follows:

- **ST\_STOP:** Previous location set in the ADMA System Address register is the error descriptor address.
- **ST\_FDS:** Current location set in the ADMA System Address register is the error descriptor address.
- **ST\_CADR:** This state is never set because it only increments the descriptor pointer and doesn't generate an ADMA error.
- **ST\_TFR:** Previous location set in the ADMA System Address register is the error descriptor address.

In case of a write operation, the Host Driver should use the ACMD22 to get the number of the written block, rather than using this information, since unwritten data may exist in the Host Controller.

The Host Controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid=0) in the ST\_FDS state. The Host Driver can distinguish this error by reading the Valid bit of the error descriptor.

**Table 10-52. ADMA Error State Coding**

D01-D00	ADMA Error State (when error has occurred)	Contents of ADMA System Address Register
00	ST_STOP (Stop DMA)	Holds the address of the next executable Descriptor command
01	ST_FDS (Fetch Descriptor)	Holds the valid Descriptor address
10	ST_CADR (Change Address)	No ADMA Error is generated
11	ST_TFR (Transfer Data)	Holds the address of the next executable Descriptor command

Address: Base address + 54h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W	[Shaded]

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0												ADMADCE	ADMALME	ADMAES	
W	[Shaded]												[Shaded]	[Shaded]	[Shaded]	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**uSDHCx\_ADMA\_ERR\_STATUS field descriptions**

Field	Description
31–4 Reserved	This read-only field is reserved and always has the value 0.
3 ADMADCE	ADMA Descriptor Error This error occurs when invalid descriptor fetched by ADMA. 1 Error 0 No Error
2 ADMALME	ADMA Length Mismatch Error This error occurs in the following 2 cases: <ul style="list-style-type: none"> <li>While the Block Count Enable is being set, the total data length specified by the Descriptor table is different from that specified by the Block Count and Block Length.</li> <li>Total data length cannot be divided by the block length.</li> </ul> 1 Error 0 No Error
ADMAES	ADMA Error State (when ADMA Error is occurred)

*Table continues on the next page...*

**uSDHCx\_ADMA\_ERR\_STATUS field descriptions (continued)**

Field	Description
	This field indicates the state of the ADMA when an error has occurred during an ADMA data transfer. Refer to <a href="#">ADMA Error Status Register (uSDHC_ADMA_ERR_STATUS)</a> for more details.

**10.3.8.22 ADMA System Address (uSDHCx\_ADMA\_SYS\_ADDR)**

This register contains the physical system memory address used for ADMA transfers.

Address: Base address + 58h offset

**uSDHCx\_ADMA\_SYS\_ADDR field descriptions**

Field	Description
31–2 ADS_ ADDR[31:0]	ADMA System Address  This register holds the word address of the executing command in the Descriptor table. At the start of ADMA, the Host Driver shall set the start address of the Descriptor table. The ADMA engine increments this register address whenever fetching a Descriptor command. When the ADMA is stopped at the Block Gap, this register indicates the address of the next executable Descriptor command. When the ADMA Error Interrupt is generated, this register shall hold the valid Descriptor address depending on the ADMA state. The lower 2 bits of this register is tied to '0' so the ADMA address is always word aligned.  Since this register supports dynamic address reflecting, when TC bit is set, it automatically alters the value of internal address counter, so SW cannot change this register when TC bit is set. Such restriction is also listed in <a href="#">Software Restrictions</a> .
Reserved	This read-only field is reserved and always has the value 0.

### 10.3.8.23 DLL (Delay Line) Control (uSDHCx\_DLL\_CTRL)

This register contains control bits for DLL.

Address: Base address + 60h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
R	DLL_CTRL_REF_UPDATE_INT[3:0]				DLL_CTRL_SLV_UPDATE_INT[7:0]								0	DLL_CTRL_SLV_DLY_TARGET1			
W																	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
R	DLL_CTRL_SLV_OVERRIDE_VAL[6:0]						DLL_CTRL_SLV_OVERRIDE	DLL_CTRL_GATE_UPDATE	DLL_CTRL_SLV_DLY_TARGET0				DLL_CTRL_SLV_FORCE_UPD	DLL_CTRL_RESET	DLL_CTRL_ENABLE		
W																	
Reset	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	

#### uSDHCx\_DLL\_CTRL field descriptions

Field	Description
31–28 DLL_CTRL_REF_UPDATE_INT[3:0]	DLL control loop update interval. The interval cycle is $(2 + \text{REF\_UPDATE\_INT}) * \text{REF\_CLOCK}$ . By default, the DLL control loop shall update every two REF_CLOCK cycles. It should be noted that increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that may effect the delay (such as voltage and temperature)
27–20 DLL_CTRL_SLV_UPDATE_INT[7:0]	Slave delay line update interval. If default 0 is used, it means 256 cycles of REF_CLOCK. A value of 0x0f results in 15 cycles and so on. Note that software can always cause an update of the slave-delay line using the SLV_FORCE_UPDATE register. Note that the slave delay line will also update automatically when the reference DLL transitions to a locked state (from an un-locked state).
19 Reserved	This read-only field is reserved and always has the value 0.
18–16 DLL_CTRL_SLV_DLY_TARGET1	Refer to DLL_CTRL_SLV_DLY_TARGET0 below.
15–9 DLL_CTRL_SLV_OVERRIDE_VAL[6:0]	When SLV_OVERRIDE = 1 This field is used to select 1 of 128 physical taps manually. A value of 0 selects tap 1, and a value of 0x7f selects tap 128.

Table continues on the next page...

## uSDHCx\_DLL\_CTRL field descriptions (continued)

Field	Description
8 DLL_CTRL_ SLV_OVERRIDE	Set this bit to 1 to Enable manual override for slave delay chain using SLV_OVERRIDE_VAL; to set 0 to disable manual override. This feature does not require the DLL to be enabled using the ENABLE bit. In fact to reduce power, if SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE = 0
7 DLL_CTRL_ GATE_UPDATE	Set this bit to 1 to prevent the DLL from updating (since when clock_in exists, glitches may appear during DLL updates). This bit may be used by software if such a condition occurs. Clear the bit to 0 to allow the DLL to update automatically.
6-3 DLL_CTRL_ SLV_DLY_ TARGET0	The delay target for the uSDHC loopback read clock can be programmed in 1/16th increments of an ref_clock half-period. The delay is $((DLL\_CTRL\_SLV\_DLY\_TARGET1 + 1) * REF\_CLOCK / 2) / 16$ So the input read-clock can be delayed relative input data from $(REF\_CLOCK / 2) / 16$ to $REF\_CLOCK * 4$ .
2 DLL_CTRL_ SLV_FORCE_ UPD	Setting this bit to 1, forces the slave delay line to update to the DLL calibrated value immediately. The slave delay line shall update automatically based on the SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the slave-line update can only occur if SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered). Be sure to use it when uSDHC is idle. This function may not work when uSDHC is working on data / cmd / response.
1 DLL_CTRL_ RESET	Setting this bit to 1 force a reset on DLL. This will cause the DLL to lose lock and re-calibrate to detect an REF_CLOCK half period phase shift. This signal is used by the DLL as edge-sensitive, so in order to create a subsequent reset, RESET must be taken low and then asserted again.
0 DLL_CTRL_ ENABLE	Set this bit to 1 to enable the DLL and delay chain; otherwise; set to 0 to bypasses DLL. Note that using the slave delay line override feature with SLV_OVERRIDE and SLV_OVERRIDE_VAL, the DLL does not need to be enabled.

### 10.3.8.24 DLL Status (uSDHCx\_DLL\_STATUS)

This register contains the DLL status information. All bits are read only and will read the same as the power-reset value.

Address: Base address + 64h offset

**uSDHCx\_DLL\_STATUS field descriptions**

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–9 DLL_STS_REF_SEL[6:0]	Reference delay line select taps. This is encoded by 7 bits for 127 taps.
8–2 DLL_STS_SLV_SEL[6:0]	Slave delay line select status. This is the instant value generated from reference chain. Since the reference chain can only be updated when REF_CLOCK is detected, this value should be the right value to be updated when the reference is locked.
1 DLL_STS_REF_LOCK	Reference DLL lock status. This signifies that the DLL has detected and locked to a half-phase ref_clock shift, allowing the slave delay-line to perform programmed clock delays
0 DLL_STS_SLV_LOCK	Slave delay-line lock status. This signifies that a valid calibration has been set to the slave-delay line and that the slave-delay line is implementing the programmed delay value

**10.3.8.25 CLK Tuning Control and Status (uSDHCx\_CLK\_TUNE\_CTRL\_STATUS)**

This register contains the Clock Tuning Control status information. All bits are read only and will read the same as the power-reset value. This register is added to support SD3.0 UHS-I SDR104 mode.

Address: Base address + 68h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	PRE_ERR	TAP_SEL_PRE[6:0]						TAP_SEL_OUT[3:0]				TAP_SEL_POST[3:0]				
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	NXT_ERR	DLY_CELL_SET_PRE[6:0]						DLY_CELL_SET_OUT[6:0]				DLY_CELL_SET_POST[6:0]				
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**uSDHCx\_CLK\_TUNE\_CTRL\_STATUS field descriptions**

Field	Description
31 PRE_ERR	PRE error which means the number of delay cells added on the feedback clock is too small. It is valid only when SMP_CLK_SEL of Mix control register (bit23 of 0x48) is enabled.

*Table continues on the next page...*

**uSDHCx\_CLK\_TUNE\_CTRL\_STATUS field descriptions (continued)**

<b>Field</b>	<b>Description</b>
30–24 TAP_SEL_ PRE[6:0]	Reflects the number of delay cells added on the feedback clock between the feedback clock and CLK_PRE.  When AUTO_TUNE_EN (bit24 of 0x48) is disabled, TAP_SEL_PRE is always equal to DLY_CELL_SET_PRE.  When AUTO_TUNE_EN (bit24 of 0x48) is enabled, TAP_SEL_PRE will be updated automatically according to the status of the auto tuning circuit to adjust the sample clock phase.
23–20 TAP_SEL_ OUT[3:0]	Reflect the number of delay cells added on the feedback clock between CLK_PRE and CLK_OUT.
19–16 TAP_SEL_ POST[3:0]	Reflect the number of delay cells added on the feedback clock between CLK_OUT and CLK_POST.
15 NXT_ERR	NXT error which means the number of delay cells added on the feedback clock is too large. It's valid only when SMP_CLK_SEL of Mix control register (bit23 of 0x48) is enabled.
14–8 DLY_CELL_ SET_PRE[6:0]	Set the number of delay cells on the feedback clock between the feedback clock and CLK_PRE.
7–4 DLY_CELL_ SET_OUT[6:0]	Set the number of delay cells on the feedback clock between CLK_PRE and CLK_OUT.
DLY_CELL_ SET_POST[6:0]	Set the number of delay cells on the feedback clock between CLK_OUT and CLK_POST.

### 10.3.8.26 Strobe DLL Control (uSDHCx\_STROBE\_DLL\_CTRL)

This register contains the strobe DLL Control information.

Address: Base address + 70h offset

**uSDHCx\_STROBE\_DLL\_CTRL field descriptions**

Field	Description
31–28 STROBE_DLL_CTRL_REF_UPDATE_INT[3:0]	Strobe DLL Control Reference Update Interval  The interval cycle is $(2 + \text{STROBE\_REF\_UPDATE\_INT}) * \text{STROBE\_REF\_CLOCK}$ . By default, the DLL control loop shall update every two STROBE_REF_CLOCK cycles.  <b>NOTE:</b> Increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that may effect the delay (such as voltage and temperature)
27–20 STROBE_DLL_CTRL_SLV_UPDATE_INT[7:0]	Strobe DLL Control Slave Update Interval  Slave delay line update interval. If default 0 is used, it means 256 cycles of STROBE_REF_CLOCK. A value of 0x0F results in 15 cycles and so on.  <b>NOTE:</b> software can always cause an update of the slave-delay line using the STROBE_SLV_FORCE_UPDATE register. The slave delay line will also update automatically when the reference DLL transitions to a locked state (from an un-locked state).
19–16 Reserved	This field is reserved.  This read-only field is reserved and always has the value 0.

Table continues on the next page...

## uSDHCx\_STROBE\_DLL\_CTRL field descriptions (continued)

Field	Description
15–9 STROBE_DLL_CTRL_SLV_OVERRIDE_VAL[6:0]	Strobe DLL Control Slave Override Value  When STROBE_SLV_OVERRIDE = 1, this field is used to manually select one of 128 physical taps. A value of 0 selects tap 1, and a value of 0x7F selects tap 128.
8 STROBE_DLL_CTRL_SLV_OVERRIDE	Strobe DLL Control Slave Override  Set this bit to 1 to Enable manual override for slave delay chain using STROBE_SLV_OVERRIDE_VAL; set this bit to 0 to disable manual override. This feature does not require the DLL to be enabled using the ENABLE bit. In fact to reduce power, if STROBE_SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE = 0.
7 STROBE_DLL_CTRL_GATE_UPDATE_1	Strobe DLL Control Gate Update  Set this bit to 1 to prevent the DLL from updating (since when STROBE_CLOCK_IN exists, glitches may appear during DLL updates). This bit can be used by software if such a condition occurs. Clear the bit to 0 to allow the DLL to update automatically.
6 STROBE_DLL_CTRL_GATE_UPDATE_0	Strobe DLL Control Gate Update  Set this bit to 1 to prevent the DLL from updating (since when STROBE_CLOCK_IN exists, glitches may appear during DLL updates). This bit can be used by software if such a condition occurs. Clear the bit to 0 to allow the DLL to update automatically.
5–3 STROBE_DLL_CTRL_SLV_DLY_TARGET	Strobe DLL Control Slave Delay Target  The delay target for the uSDHC loopback read clock can be programmed in 1/16th increments of an STROBE_REF_CLOCK half-period. The delay is $((\text{STROBE\_DLL\_CTRL\_SLV\_DLY\_TARGET} + 1) * \text{STROBE\_REF\_CLOCK} / 2) / 16$ , So the input read-clock can be delayed relative input data from $(\text{STROBE\_REF\_CLOCK} / 2) / 16$ to $(\text{STROBE\_REF\_CLOCK} * 4) / 16$ .
2 STROBE_DLL_CTRL_SLV_FORCE_UPD	Strobe DLL Control Slave Force Updated  Setting this bit to 1, forces the slave delay line to update to the DLL calibrated value immediately. The slave delay line should automatically update the STROBE_SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the slave-line update can only occur if STROBE_SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered). Be sure to use it when uSDHC is idle. This function may not work when uSDHC is working on data / cmd / response.
1 STROBE_DLL_CTRL_RESET	Strobe DLL Control Reset  Setting this bit to 1 to force a reset on DLL. This will cause the DLL to lose lock and re-calibrate to detect an REF_CLOCK half period phase shift. This signal is used by the DLL as edge-sensitive, in order to create a subsequent reset, RESET must be taken low and then asserted again.
0 STROBE_DLL_CTRL_ENABLE	Strobe DLL Control Enable  Set this bit to 1 to enable the DLL and delay chain; otherwise, set to 0 to bypasses DLL. <b>NOTE:</b> Using the slave delay line override feature with STROBE_SLV_OVERRIDE and STROBE_SLV_OVERRIDE VAL, the DLL does not need to be enabled.

### 10.3.8.27 Strobe DLL Status (uSDHCx\_STROBE\_DLL\_STATUS)

This register contains the strobe DLL status information. All bits are read only and read the same as the power-reset value.

Address: Base address + 74h offset

**uSDHCx\_STROBE\_DLL\_STATUS field descriptions**

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15–9 STROBE_DLL_STS_REF_SEL[6:0]	Strobe DLL Status Reference Select Reference delay line select taps. This is encoded by 7 bits for 127 taps.
8–2 STROBE_DLL_STS_SLV_SEL[6:0]	Strobe DLL Status Slave Select Slave delay line select status. This is the instant value generated from reference chain. Since the reference chain can only be updated when STROBE_REF_CLOCK is detected, this value can be updated with the right value when the reference is locked.
1 STROBE_DLL_STS_REF_LOCK	Strobe DLL Status Reference Lock This signifies that the DLL has detected and locked to a half-phase REF_CLOCK shift, it allows the slave delay-line to perform programmed clock delays.

Table continues on the next page...

**uSDHCx\_STROBE\_DLL\_STATUS field descriptions (continued)**

Field	Description
0 STROBE_DLL_STS_SLV_LOCK	Strobe DLL Status Slave Lock Slave delay-line lock status. This signifies that a valid calibration has been set to the slave-delay line, and the slave-delay line is implementing the programmed delay value.

**10.3.8.28 Vendor Specific Register (uSDHCx\_VEND\_SPEC)**

This register contains the vendor specific control / status register.

Address: Base address + C0h offset

## uSDHCx\_VEND\_SPEC field descriptions

Field	Description
31 CMD_BYTE_EN	Byte access 0 Disable 1 Enable
30 -	Reserved. Always write as 0.
29 -	Reserved. Always write as 1.
28 -	Reserved. Always write as 0.
27–24 -	Reserved. Always write as 4'b0000.
23–16 INT_ST_VAL[7:0]	Internal State Value Internal state value, reflecting the corresponding state value selected by Debug Select field. This field is read-only and write to this field does not have effect.
15 CRC_CHK_DIS	CRC Check Disable 0 Check CRC16 for every read data packet and check CRC bits for every write data packet 1 Ignore CRC16 check for every read data packet and ignore CRC bits check for every write data packet
14 CARD_CLK_SOFT_EN	Card Clock Software Enable 0 Gate off the sd_clk 1 Enable the sd_clk
13 IPG_PERCLK_SOFT_EN	IPG_PERCLK Software Enable 0 Gate off the IPG_PERCLK 1 Enable the IPG_PERCLK
12 HCLK_SOFT_EN	AHB Clock Software Enable  <b>NOTE:</b> Hardware auto-enables the AHB clock when the internal DMA is enabled even if HCLK_SOFT_EN is 0.  0 Gate off the AHB clock. 1 Enable the AHB clock.
11 IPG_CLK_SOFT_EN	IPG_CLK Software Enable 0 Gate off the IPG_CLK 1 Enable the IPG_CLK
10 -	Reserved. Always write as 0.
9 -	Reserved. Always write as 0.
8 FRC_SDCLK_ON	Force CLK output active 0 CLK active or inactive is fully controlled by the hardware. 1 Force CLK active.

Table continues on the next page...

## uSDHCx\_VEND\_SPEC field descriptions (continued)

Field	Description
7 CLKONJ_IN_ ABORT	<p>Only for debug.</p> <p>Force CLK output active when sending Abort command:</p> <p>0 The CLK output is active when sending abort command while data is transmitting even if the internal FIFO is full (for read) or empty (for write).</p> <p>1 The CLK output is inactive when sending abort command while data is transmitting if the internal FIFO is full (for read) or empty (for write).</p>
6 WP_POL	<p>Only for debug.</p> <p>Polarity of the WP pin:</p> <p>0 WP pin is high active.</p> <p>1 WP pin is low active.</p>
5 CD_POL	<p>Only for debug.</p> <p>Polarity of the CD_B pin:</p> <p>0 CD_B pin is low active.</p> <p>1 CD_B pin is high active.</p>
4 DAT3_CD_POL	<p>Only for debug.</p> <p>Polarity of DATA3 pin when it is used as card detection.</p> <p>0 Card detected when DATA3 is high.</p> <p>1 Card detected when DATA3 is low.</p>
3 AC12_WR_ CHKBUSY_EN	<p>Check busy enable after auto CMD12 for write data packet</p> <p>0 Do not check busy after auto CMD12 for write data packet</p> <p>1 Check busy after auto CMD12 for write data packet</p>
2 CONFLICT_ CHK_EN	<p>Conflict check enable.</p> <p>It is not implemented in uSDHC IP.</p> <p>0 Conflict check disable</p> <p>1 Conflict check enable</p>
1 VSELECT	<p>Voltage Selection</p> <p>Change the value of output signal VSELECT, to control the voltage on pads for external card. There must be a control circuit out of uSDHC to change the voltage on pads.</p> <p>1 Change the voltage to low voltage range, around 1.8 V</p> <p>0 Change the voltage to high voltage range, around 3.0 V</p>
0 EXT_DMA_EN	<p>External DMA Request Enable</p> <p>Enable the request to external DMA. When the internal DMA (either Simple DMA or Advanced DMA) is not in use, and this bit is set, uSDHC will send out DMA request when the internal buffer is ready. This bit is particularly useful when transferring data by ARM platform polling mode, and it is not allowed to send out the external DMA request. By default, this bit is set.</p> <p>0 In any scenario, uSDHC does not send out external DMA request.</p> <p>1 When internal DMA is not active, the external DMA request will be sent out.</p>

### 10.3.8.29 MMC Boot Register (uSDHCx\_MMC\_BOOT)

This register contains the MMC Fast Boot control register.

Address: Base address + C4h offset

#### uSDHCx\_MMC\_BOOT field descriptions

Field	Description
31–16 BOOT_BLK_CNT[15:0]	The value defines the Stop At Block Gap value of automatic mode. When received card block cnt is equal to (BLK_CNT - BOOT_BLK_CNT) and AUTO_SABG_EN is 1, then Stop At Block Gap. Here, BLK_CNT is defined in the Block Attributes Register, bit31 - 16 of 0x04.
15–9 Reserved	This read-only field is reserved and always has the value 0.
8 DISABLE_TIME_OUT	Disable Time Out  <b>NOTE:</b> When this bit is set, there is no timeout check no matter whether BOOT_EN is set or not.  0 Enable time out 1 Disable time out
7 AUTO_SABG_EN	During boot, enable auto stop at block gap function. This function will be triggered, and host will stop at block gap when received card block cnt is equal to (BLK_CNT - BOOT_BLK_CNT).
6 BOOT_EN	Boot mode enable  0 Fast boot disable 1 Fast boot enable
5 BOOT_MODE	Boot mode select

Table continues on the next page...

**uSDHCx\_MMC\_BOOT field descriptions (continued)**

Field	Description
	0 Normal boot 1 Alternative boot
4 BOOT_ACK	Boot ACK mode select  0 No ack 1 Ack
DTOCV_ ACK[3:0]	Boot ACK time out counter value.  0000 SDCLK x 2 <sup>13</sup> 0001 SDCLK x 2 <sup>14</sup> 0010 SDCLK x 2 <sup>15</sup> 0011 SDCLK x 2 <sup>16</sup> 0100 SDCLK x 2 <sup>17</sup> 0101 SDCLK x 2 <sup>18</sup> 0110 SDCLK x 2 <sup>19</sup> 0111 SDCLK x 2 <sup>20</sup> 1110 SDCLK x 2 <sup>27</sup> 1111 SDCLK x 2 <sup>28</sup>

**10.3.8.30 Vendor Specific 2 Register (uSDHCx\_VEND\_SPEC2)**

This register contains the vendor specific control 2 register.

Address: Base address + C8h offset

### uSDHCx\_VEND\_SPEC2 field descriptions

Field	Description
31–12 -	This field is reserved. Reserved
11 HS400_RD_ CLK_STOP_EN	HS400 Read Clock Stop Enable Only stop clock at read block gap.
10 HS400_WR_ CLK_STOP_EN	HS400 Write Clock Stop Enable Only stop clock at write block gap.
9 Reserved	This read-only field is reserved and always has the value 0.
8 Reserved	This read-only field is reserved and always has the value 0.
7 CARD_INT_ AUTO_CLR_DIS	Disable the feature to clear the Card interrupt status bit when Card Interrupt status enable bit is cleared. Only for debug.  0 Card interrupt status bit (CINT) can be cleared when Card Interrupt status enable bit is 0. 1 Card interrupt status bit (CINT) can only be cleared by writing a 1 to CINT bit.
6 TUNING_CMD_ EN	Enable the auto tuning circuit to check the CMD line.  0 Auto tuning circuit does not check the CMD line. 1 Auto tuning circuit checks the CMD line.
5 TUNING_1bit_EN	Enable the auto tuning circuit to check the DATA0 only. It is used with the TUNING_8bit_EN together.
4 TUNING_8bit_EN	Enable the auto tuning circuit to check the DATA[7:0]. It is used with the TUNING_1bit_EN together.  <b>NOTE:</b> The format of these two bits are [TUNNING_8bit_EN:TUNNING_1bit_EN].  00 Tuning circuit only checks the DATA[3:0]. 01 Tuning circuit only checks the DATA0. 10 Tuning circuit checks the whole DATA[7:0]. 11 Invalid.
3 CARD_INT_D3_ TEST	Card Interrupt Detection Test This bit only uses for debugging.  0 Check the card interrupt only when DATA3 is high. 1 Check the card interrupt by ignoring the status of DATA3.
2 SDR104_NSD_ DIS	Interrupt window after abort command is sent. This bit only uses for debugging.  0 Enable the interrupt window 9 cycles later after the end of the I/O abort command (or CMD12) is sent. 1 Enable the interrupt window 5 cycles later after the end of the I/O abort command (or CMD12) is sent.
1 SDR104_OE_ DIS	CMD_OE / DATA_OE logic generation test. This bit only uses for debugging.  0 Drive the CMD_OE / DATA_OE for one more clock cycle after the end bit. 1 Stop to drive the CMD_OE / DATA_OE at once after driving the end bit.

Table continues on the next page...

**uSDHCx\_VEND\_SPEC2 field descriptions (continued)**

Field	Description
0 SDR104_ TIMING_DIS	Timeout counter test. This bit only uses for debugging.  0 The timeout counter for Ncr changes to 80, Ncrc changes to 21. 1 The timeout counter for Ncr changes to 72, Ncrc changes to 15.

**10.3.8.31 Tuning Control Register (uSDHCx\_TUNING\_CTRL)**

The register contains configuration of tuning circuit.

Address: Base address + CCh offset

**uSDHCx\_TUNING\_CTRL field descriptions**

Field	Description
31-25 -	Reserved

Table continues on the next page...

**uSDHCx\_TUNING\_CTRL field descriptions (continued)**

<b>Field</b>	<b>Description</b>
24 STD_TUNING_ EN	Standard tuning circuit and procedure enable: This bit is used to enable standard tuning circuit and procedure.
23 -	Reserved
22–20 TUNING_ WINDOW	Select data window value for auto tuning
19 -	Reserved
18–16 TUNING_STEP	The increasing delay cell steps in tuning procedure.
15–8 TUNING_ COUNTER	The MAX repeat CMD19 times in tuning procedure.
TUNING_ START_TAP	The start dealy cell point when send first CMD19 in tuning procedure.

# Chapter 11

## Connectivity

### 11.1 Ethernet MAC (ENET)

#### 11.1.1 Introduction

The MAC-NET core, in conjunction with a 10/100/1000-Mbit/s MAC, implements layer 3 network acceleration functions. These functions are designed to accelerate the processing of various common networking protocols, such as IP, TCP, UDP, and ICMP, providing wire speed services to client applications.

#### 11.1.2 Overview

The core implements a triple-speed 10/100/1000-Mbit/s Ethernet MAC compliant with the IEEE802.3-2002 standard. The MAC layer provides compatibility with half- or full-duplex 10/100-Mbit/s and full-duplex gigabit Ethernet LANs.

The MAC operation is fully programmable and can be used in Network Interface Card (NIC), bridging, or switching applications. The core implements the remote network monitoring (RMON) counters according to IETF RFC 2819.

The core also implements a hardware acceleration block to optimize the performance of network controllers providing TCP/IP, UDP, and ICMP protocol services. The acceleration block performs critical functions in hardware, which are typically implemented with large software overhead.

The core implements programmable embedded FIFOs that can provide buffering on the receive path for lossless flow control.

Advanced power management features are available with magic packet detection and programmable power-down modes.

A unified DMA (uDMA), internal to the ENET module, optimizes data transfer between the ENET core and the SoC, and supports an enhanced buffer descriptor programming model to support IEEE 1588 functionality.

The programmable Ethernet MAC with IEEE 1588 integrates a standard IEEE 802.3 Ethernet MAC with a time-stamping module. The IEEE 1588 standard provides accurate clock synchronization for distributed control nodes for industrial automation applications.

### **11.1.2.1 Features**

The MAC-NET core includes the following features.

#### **11.1.2.1.1 Ethernet MAC features**

- Implements the full 802.3 specification with preamble/SFD generation, frame padding generation, CRC generation and checking
- Supports zero-length preamble
- Dynamically configurable to support 10/100-Mbit/s and gigabit operation
- Supports 10/100 Mbit/s full-duplex and configurable half-duplex operation
- Supports gigabit full-duplex operation
- Compliant with the AMD magic packet detection with interrupt for node remote power management
- Seamless interface to commercial ethernet PHY devices via one of the following:
  - a 4-bit Media Independent Interface (MII) operating at 2.5/25 MHz.
  - a 4-bit non-standard MII-Lite (MII without the CRS and COL signals) operating at 2.5/25 MHz.
  - a 2-bit Reduced MII (RMII) operating at 50 MHz.
  - a (double data rate) 4-bit Reduced GMII (RGMII) operating at 125 MHz.
- Simple 64-Bit FIFO user-application interface
- CRC-32 checking at full speed with optional forwarding of the frame check sequence (FCS) field to the client
- CRC-32 generation and append on transmit or forwarding of user application provided FCS selectable on a per-frame basis
- In full-duplex mode:
  - Implements automated pause frame (802.3 x31A) generation and termination, providing flow control without user application intervention
  - Pause quanta used to form pause frames — dynamically programmable
  - Pause frame generation additionally controllable by user application offering flexible traffic flow control
  - Optional forwarding of received pause frames to the user application
  - Implements standard flow-control mechanism

- In half-duplex mode: provides full collision support, including jamming, backoff, and automatic retransmission
- Supports VLAN-tagged frames according to IEEE 802.1Q
- Programmable MAC address: Insertion on transmit; discards frames with mismatching destination address on receive (except broadcast and pause frames)
- Programmable promiscuous mode support to omit MAC destination address checking on receive
- Multicast and unicast address filtering on receive based on 64-entry hash table, reducing higher layer processing load
- Programmable frame maximum length providing support for any standard or proprietary frame length
- Statistics indicators for frame traffic and errors (alignment, CRC, length) and pause frames providing for IEEE 802.3 basic and mandatory management information database (MIB) package and remote network monitoring (RFC 2819)
- Simple handshake user application FIFO interface with fully programmable depth and threshold levels
- Provides separate status word for each received frame on the user interface providing information such as frame length, frame type, VLAN tag, and error information
- Multiple internal loopback options
- MDIO master interface for PHY device configuration and management supports two programmable MDIO base addresses, and standard (IEEE 802.3 Clause 22) and extended (Clause 45) MDIO frame formats
- Supports legacy FEC buffer descriptors
- Interrupt coalescing reduces the number of interrupts generated by the MAC, reducing CPU loading
- Traffic-shaping bandwidth distribution supports credit-based and round-robin-based policies. Either policy can be combined with time-based shaping.
- AVB (Audio Video Bridging, IEEE 802.1Qav) features:
  - Credit-based bandwidth distribution policy can be combined with time-based shaping
  - AVB endpoint talker and listener support
  - Support for arbitration between different priority traffic (for example, AVB class A, AVB class B, and non-AVB)

#### **11.1.2.1.2 IP protocol performance optimization features**

- Operates on TCP/IP and UDP/IP and ICMP/IP protocol data or IP header only
- Enables wire-speed processing
- Supports IPv4 and IPv6
- Transparent passing of frames of other types and protocols

- Supports VLAN tagged frames according to IEEE 802.1q with transparent forwarding of VLAN tag and control field
- Automatic IP-header and payload (protocol specific) checksum calculation and verification on receive
- Automatic IP-header and payload (protocol specific) checksum generation and automatic insertion on transmit configurable on a per-frame basis
- Supports IP and TCP, UDP, ICMP data for checksum generation and checking
- Supports full header options for IPv4 and TCP protocol headers
- Provides IPv6 support to datagrams with base header only — datagrams with extension headers are passed transparently unmodified/unchecked
- Provides statistics information for received IP and protocol errors
- Configurable automatic discard of erroneous frames
- Configurable automatic host-to-network (RX) and network-to-host (TX) byte order conversion for IP and TCP/UDP/ICMP headers within the frame
- Configurable padding remove for short IP datagrams on receive
- Configurable Ethernet payload alignment to allow for 32-bit word-aligned header and payload processing
- Programmable store-and-forward operation with clock and rate decoupling FIFOs

### 11.1.2.1.3 IEEE 1588 features

- Supports all IEEE 1588 frames.
- Allows reference clock to be chosen independently of network speed.
- Software-programmable precise time-stamping of ingress and egress frames
- Timer monitoring capabilities for system calibration and timing accuracy management
- Precise time-stamping of external events with programmable interrupt generation
- Programmable event and interrupt generation for external system control
- Supports hardware- and software-controllable timer synchronization.
- Provides a 4-channel IEEE 1588 timer. Each channel supports input capture and output compare using the 1588 counter.

## 11.1.2.2 Block diagram

Figure 11-1. Ethernet MAC-NET core block diagram

## 11.1.3 External Signals

The table found here describes the external signals of ENET.

Table 11-1. ENET External Signals

Signal	Description	Mode	Pad	Alt Mode	Direction
ENET1_1588_EVENT0_I N	Capture/compare block input/output event bus signal. When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRn register for inspection by software. When configured for compare, the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCRn. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set.	MII/RMII/ RGMII	UART3_RX D	ALT4	I

Table continues on the next page...

**Table 11-1. ENET External Signals (continued)**

Signal	Description	Mode	Pad	Alt Mode	Direction
ENET1_1588_EVENT0_OUT	<p>Capture/compare block input/output event bus signal. When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRN register for inspection by software. When configured for compare, the corresponding signal 1588_EVENT is asserted when the timer reaches the compare value programmed in register ENET_TCCRN. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set.</p> <p><b>NOTE:</b> ENET_1588_EVENT0_OUT has a programmable output width, see IOMUXC_GPR0[CLK_STRETCH] delayed one clock cycle in relation to all other EVENTx_OUT signals</p>	MII/RMII/RGMII	UART3_TXD	ALT4	O
ENET1_1588_EVENT1_IN	<p>Capture/compare block input/output event bus signal. When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRN register for inspection by software. When configured for compare, the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCRN. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set.</p>	MII/RMII/RGMII	UART3_RTS	ALT4	I
ENET1_1588_EVENT1_OUT	<p>Capture/compare block input/output event bus signal. When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRN register for inspection by software. When configured for compare, the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCRN. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set.</p>	MII/RMII/RGMII	UART3_CTS	ALT4	O
ENET1_1588_EVENT2_IN	<p>Capture/compare block input/output event bus signal. When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRN register for inspection by software. When configured for compare,</p>	MII/RMII/RGMII	LCD1_CLK	ALT2	I

**Table 11-1. ENET External Signals (continued)**

Signal	Description	Mode	Pad	Alt Mode	Direction
	the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCRn. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set.				
ENET1_1588_EVENT2_OUT	Capture/compare block input/output event bus signal. When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRn register for inspection by software. When configured for compare, the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCRn. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set.	MII/RMII/RGMII	LCD1_DATA20	ALT2	O
ENET1_1588_EVENT3_IN	Capture/compare block input/output event bus signal. When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRn register for inspection by software. When configured for compare, the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCRn. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set.	MII/RMII/RGMII	LCD1_ENABLE	ALT2	I
ENET1_1588_EVENT3_OUT	Capture/compare block input/output event bus signal. When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRn register for inspection by software. When configured for compare, the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCRn. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set.	MII/RMII/RGMII	LCD1_DATA21	ALT2	O
ENET1_COL	Asserted upon detection of a collision and remains asserted while the collision persists. This signal is not defined for full duplex mode.	MII	ENET1_COLL	ALT0	I

*Table continues on the next page...*

**Table 11-1. ENET External Signals (continued)**

Signal	Description	Mode	Pad	Alt Mode	Direction
ENET1_CR_S	Carrier sense. When asserted, indicates transmit or receive medium is not idle.	MII	ENET1_CR_S	ALT0	I
ENET1_MDC	Output clock provides a timing reference to the PHY for data transfers on the MDIO signal.	MII/RMII/RGMII	GPIO1_IO11	ALT2	O
			SD2_WP	ALT1	
			UART1_TXD	ALT6	
ENET1_MDIO	Transfers control information between the external PHY and the mediaaccess controller. Data is synchronous to MDC. This signal is an input after reset.	MII/RMII/RGMII	GPIO1_IO10	ALT2	IO
			SD2_CD_B	ALT1	
			UART1_RXD	ALT6	
ENET1_RX_CLK	In MII mode, provides a timing reference for RX_EN, RX_DATA[3:0], and RX_ER.	MII	ENET1_RX_CLK	ALT0	I
ENET1_RX_ER	When asserted with RXDV, indicates the PHY detects an error in the current frame.	MII/RMII	ENET1_RX_C	ALT1	I
ENET1_TX_CLK	Input clock, which provides a timing reference for TX_EN, TX_DATA[3:0], and TX_ER.	MII	ENET1_TX_CLK	ALT0	O
ENET1_TX_ER	When asserted for one or more clock cycles while TXEN is also asserted, PHY sends one or more illegal symbols.	MII	ENET1_TX_C	ALT1	O
RGMI1_RD0	Contains the Ethernet input data transferred from the PHY to the media-access controller when RX_EN is asserted.	RGMI/RMII/MII	ENET1_RDATA0	ALT0	I
RGMI1_RD1	Contains the Ethernet input data transferred from the PHY to the media-access controller when RX_EN is asserted.	RGMI/RMII/MII	ENET1_RDATA1	ALT0	I
RGMI1_RD2	Contains the Ethernet input data transferred from the PHY to the media-access controller when RX_EN is asserted.	RGMI/RMII	ENET1_RDATA2	ALT0	I
RGMI1_RD3	Contains the Ethernet input data transferred from the PHY to the media-access controller when RX_EN is asserted.	RGMI/RMII	ENET1_RDATA3	ALT0	I
RGMI1_RX_CTL	In RGMII mode, contains RX_EN on the rising edge of RGMII_RXC, and a logical derivative of RX_EN and RX_ER (RX_EN XOR RX_ER) on the falling edge of RGMII_RXC.	RGMI	ENET1_RX_CTL	ALT0	I
RGMI1_RXC	In RGMII mode, provides a timing reference for RX_DATA[3:0] and RX_CTL.	RGMI/RMII	ENET1_RX_C	ALT0	I

Table continues on the next page...

**Table 11-1. ENET External Signals (continued)**

Signal	Description	Mode	Pad	Alt Mode	Direction
RGMI1_TD0	Serial output Ethernet data. Only valid during TX_EN assertion.	RGMI1/ RMII/MII	ENET1_TD ATA0	ALT0	O
RGMI1_TD1	Serial output Ethernet data. Only valid during TX_EN assertion.	RGMI1/ RMII/MII	ENET1_TD ATA1	ALT0	O
RGMI1_TD2	Serial output Ethernet data. Only valid during TX_EN assertion.	RGMI1/MII	ENET1_TD ATA2	ALT0	O
RGMI1_TD3	Serial output Ethernet data. Only valid during TX_EN assertion.	RGMI1/MII	ENET1_TD ATA3	ALT0	O
RGMI1_TX_CTL	In RGMI1 mode, contains TX_EN on the rising edge of RGMI1_TXC, and a logical derivative of TX_EN and TX_ER (TX_EN XOR TX_ER) on the falling edge of RGMI1_TXC.	RGMI1	ENET1_TX_ CTL	ALT0	O
RGMI1_TXC	In RGMI1 mode, provides a timing reference for TX_DATA[3:0] and TX_CTL.	RGMI1	ENET1_TX C	ALT0	O
ENET2_1588_EVENT0_I N	Capture/compare block input/output event bus signal. When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRN register for inspection by software. When configured for compare, the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCRN. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set.	MII/RMII/ RGMI1	UART1_RX D	ALT4	I
ENET2_1588_EVENT0_O UT	Capture/compare block input/output event bus signal. When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRN register for inspection by software. When configured for compare, the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCRN. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set.  <b>NOTE:</b> ENET_1588_EVENT0_OUT has programmable output width, see IOMUXC_GPR0[CLK_STRETCH] delayed one clock cycle in relation to all other EVENTx_OUT signals	MII/RMII/ RGMI1	UART1_TX D	ALT4	O
ENET2_1588_EVENT1_I N	Capture/compare block input/output event bus signal. When configured for	MII/RMII/ RGMI1	UART2_RX D	ALT4	I

**Table 11-1. ENET External Signals (continued)**

Signal	Description	Mode	Pad	Alt Mode	Direction
	capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRn register for inspection by software. When configured for compare, the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCRn. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set.				
ENET2_1588_EVENT1_OUT	Capture/compare block input/output event bus signal. When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRn register for inspection by software. When configured for compare, the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCRn. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set.	MII/RMII/RGMII	UART2_TXD	ALT4	O
ENET2_1588_EVENT2_IN	Capture/compare block input/output event bus signal. When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRn register for inspection by software. When configured for compare, the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCRn. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set.	MII/RMII/RGMII	LCD1_HSYNC	ALT2	I
ENET2_1588_EVENT2_OUT	Capture/compare block input/output event bus signal. When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRn register for inspection by software. When configured for compare, the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCRn. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set.	MII/RMII/RGMII	LCD1_DATA22	ALT2	O

*Table continues on the next page...*

**Table 11-1. ENET External Signals (continued)**

Signal	Description	Mode	Pad	Alt Mode	Direction
ENET2_1588_EVENT3_IN	Capture/compare block input/output event bus signal. When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRn register for inspection by software. When configured for compare, the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCRn. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set.	MII/RMII/RGMII	LCD1_VSYNC	ALT2	I
ENET2_1588_EVENT3_OUT	Capture/compare block input/output event bus signal. When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRn register for inspection by software. When configured for compare, the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCRn. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set.	MII/RMII/RGMII	LCD1_DATA23	ALT2	O
ENET2_COL	Asserted upon detection of a collision and remains asserted while the collision persists. This signal is not defined for full duplex mode.	MII	EPDC1_PWRSTAT	ALT2	I
ENET2_CRS	Carrier sense. When asserted, indicates transmit or receive medium is not idle.	MII	EPDC1_PWRCOM	ALT2	I
ENET2_MDC	Output clock provides a timing reference to the PHY for data transfers on the MDIO signal.	MII/RMII/RGMII	GPIO1_IO15	ALT2	O
			SD2_WP	ALT2	
			UART2_TXD	ALT6	
ENET2_MDIO	Transfers control information between the external PHY and the media access controller. Data is synchronous to MDC. This signal is an input after reset.	MII/RMII/RGMII	GPIO1_IO14	ALT2	IO
			SD2_CD_B	ALT2	
			UART2_RXD	ALT6	
ENET2_RX_CLK	In MII mode, provides a timing reference for RX_EN, RX_DATA[3:0], and RX_ER.	MII	EPDC1_BDR1	ALT2	I
ENET2_RX_ER	When asserted with RXDV, indicates the PHY detects an error in the current frame.	MII/RMII	EPDC1_SDCE1	ALT3	I

Table continues on the next page...

**Table 11-1. ENET External Signals (continued)**

Signal	Description	Mode	Pad	Alt Mode	Direction
ENET2_TX_CLK	Input clock, which provides a timing reference for TX_EN, TX_DATA[3:0], and TX_ER.	MII	EPDC1_BDR0	ALT2	O
ENET2_TX_ER	When asserted for one or more clock cycles while TXEN is also asserted, PHY sends one or more illegal symbols.	MII/RMII	EPDC1_GDSP	ALT3	O
RGMII2_RD0	Contains the Ethernet input data transferred from the PHY to the media-access controller when RX_EN is asserted.	RMII/RGMII	EPDC1_SDCLK	ALT2	I
RGMII2_RD1	Contains the Ethernet input data transferred from the PHY to the media-access controller when RX_EN is asserted.	RMII/RGMII	EPDC1_SDL	ALT2	I
RGMII2_RD2	Contains the Ethernet input data transferred from the PHY to the media-access controller when RX_EN is asserted.	RGMII	EPDC1_SDOE	ALT2	I
RGMII2_RD3	Contains the Ethernet input data transferred from the PHY to the media-access controller when RX_EN is asserted.	RGMII	EPDC1_SDSHR	ALT2	I
RGMII2_RX_CTL	In RGMII mode, contains RX_EN on the rising edge of RGMII_RXC, and a logical derivative of RX_EN and RX_ER (RX_EN XOR RX_ER) on the falling edge of RGMII_RXC.	RMII/RGMII	EPDC1_SDC0	ALT2	I
RGMII2_RXC	In RGMII mode, provides a timing reference for RX_DATA[3:0] and RX_CTL.	RMII/RGMII	EPDC1_SDC1	ALT2	I
RGMII2_TD0	Serial output Ethernet data. Only valid during TX_EN assertion.	RMII/RGMII	EPDC1_SDC2	ALT2	O
RGMII2_TD1	Serial output Ethernet data. Only valid during TX_EN assertion.	RMII/RGMII	EPDC1_SDC3	ALT2	O
RGMII2_TD2	Serial output Ethernet data. Only valid during TX_EN assertion.	RGMII	EPDC1_GDCLK	ALT2	O
RGMII2_TD3	Serial output Ethernet data. Only valid during TX_EN assertion.	RGMII	EPDC1_GDOE	ALT2	O
RGMII2_TX_CTL	In RGMII mode, contains TX_EN on the rising edge of RGMII_TXC, and a logical derivative of TX_EN and TX_ER (TX_EN XOR TX_ER) on the falling edge of RGMII_TXC.	RMII/RGMII	EPDC1_GDRL	ALT2	O
RGMII2_TXC	In RGMII mode, provides a timing reference for TX_DATA[3:0] and TX_CTL.	RGMII	EPDC1_GDSP	ALT2	O

## 11.1.4 Clocks

The table found here describes the clock sources for ENET. Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

**Table 11-2. ENET Clocks**

Clock name	Clock Root	Description
ipg_clk	ENET_AXI_CLK_ROOT	Module clock
ipg_clk_mac0	ENET_AXI_CLK_ROOT	MAC peripheral clock
ipg_clk_mac0_s	ENET_AXI_CLK_ROOT	MAC peripheral access clock
ipg_clk_s	ENET_AXI_CLK_ROOT	Peripheral access clock
ipg_clk_time	ENET1_TIME_CLK_ROOT	Peripheral clock
mac0_rxmem_clk	ENET_AXI_CLK_ROOT	MAC receive memory clock
mac0_txmem_clk	ENET_AXI_CLK_ROOT	MAC transmit memory clock

## 11.1.5 Memory map/register definition

ENET registers must be read or written with 32-bit accesses. Non-32 bit accesses will terminate with an error.

Reserved bits should be written with 0 and ignored on read. Unused registers read zero and a write has no effect.

This table shows Ethernet registers organization.

**Table 11-3. Register map summary**

Offset Address	Section	Description
0x0000 – 0x01FF	Configuration	Core control and status registers
0x0200 – 0x03FF	Statistics counters	MIB and Remote Network Monitoring (RFC 2819) registers
0x0400 – 0x0430	1588 control	1588 adjustable timer (TSM) and 1588 frame control
0x0600 – 0x07FC	Capture/Compare block	Registers for the Capture/Compare block

## ENET memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
30BE_0004	Interrupt Event Register (ENET1_EIR)	32	w1c	0000_0000h	<a href="#">11.1.5.1/2887</a>
30BE_0008	Interrupt Mask Register (ENET1_EIMR)	32	R/W	0000_0000h	<a href="#">11.1.5.2/2890</a>
30BE_0010	Receive Descriptor Active Register - Ring 0 (ENET1_RDAR)	32	R/W	0000_0000h	<a href="#">11.1.5.3/2894</a>
30BE_0014	Transmit Descriptor Active Register - Ring 0 (ENET1_TDAR)	32	R/W	0000_0000h	<a href="#">11.1.5.4/2895</a>
30BE_0024	Ethernet Control Register (ENET1_ECR)	32	R/W	See section	<a href="#">11.1.5.5/2896</a>
30BE_0040	MII Management Frame Register (ENET1_MMFR)	32	R/W	0000_0000h	<a href="#">11.1.5.6/2898</a>
30BE_0044	MII Speed Control Register (ENET1_MSCR)	32	R/W	0000_0000h	<a href="#">11.1.5.7/2899</a>
30BE_0064	MIB Control Register (ENET1_MIBC)	32	R/W	C000_0000h	<a href="#">11.1.5.8/2901</a>
30BE_0084	Receive Control Register (ENET1_RCR)	32	R/W	05EE_0001h	<a href="#">11.1.5.9/2902</a>
30BE_00C4	Transmit Control Register (ENET1_TCR)	32	R/W	0000_0000h	<a href="#">11.1.5.10/2905</a>
30BE_00E4	Physical Address Lower Register (ENET1_PALR)	32	R/W	0000_0000h	<a href="#">11.1.5.11/2907</a>
30BE_00E8	Physical Address Upper Register (ENET1_PAUR)	32	R/W	0000_8808h	<a href="#">11.1.5.12/2907</a>
30BE_00EC	Opcode/Pause Duration Register (ENET1_OPD)	32	R/W	0001_0000h	<a href="#">11.1.5.13/2908</a>
30BE_00F0	Transmit Interrupt Coalescing Register (ENET1_TXIC0)	32	R/W	0000_0000h	<a href="#">11.1.5.14/2908</a>
30BE_00F4	Transmit Interrupt Coalescing Register (ENET1_TXIC1)	32	R/W	0000_0000h	<a href="#">11.1.5.14/2908</a>
30BE_00F8	Transmit Interrupt Coalescing Register (ENET1_TXIC2)	32	R/W	0000_0000h	<a href="#">11.1.5.14/2908</a>
30BE_0100	Receive Interrupt Coalescing Register (ENET1_RXIC0)	32	R/W	0000_0000h	<a href="#">11.1.5.15/2909</a>
30BE_0104	Receive Interrupt Coalescing Register (ENET1_RXIC1)	32	R/W	0000_0000h	<a href="#">11.1.5.15/2909</a>
30BE_0108	Receive Interrupt Coalescing Register (ENET1_RXIC2)	32	R/W	0000_0000h	<a href="#">11.1.5.15/2909</a>
30BE_0118	Descriptor Individual Upper Address Register (ENET1_IAUR)	32	R/W	0000_0000h	<a href="#">11.1.5.16/2910</a>
30BE_011C	Descriptor Individual Lower Address Register (ENET1_IALR)	32	R/W	0000_0000h	<a href="#">11.1.5.17/2911</a>
30BE_0120	Descriptor Group Upper Address Register (ENET1_GAUR)	32	R/W	0000_0000h	<a href="#">11.1.5.18/2911</a>

Table continues on the next page...

## ENET memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
30BE_0124	Descriptor Group Lower Address Register (ENET1_GALR)	32	R/W	0000_0000h	<a href="#">11.1.5.19/2912</a>
30BE_0144	Transmit FIFO Watermark Register (ENET1_TFWR)	32	R/W	0000_0000h	<a href="#">11.1.5.20/2912</a>
30BE_0160	Receive Descriptor Ring 1 Start Register (ENET1_RDSCR1)	32	R/W	0000_0000h	<a href="#">11.1.5.21/2913</a>
30BE_0164	Transmit Buffer Descriptor Ring 1 Start Register (ENET1_TDSR1)	32	R/W	0000_0000h	<a href="#">11.1.5.22/2914</a>
30BE_0168	Maximum Receive Buffer Size Register - Ring 1 (ENET1_MRBR1)	32	R/W	0000_0000h	<a href="#">11.1.5.23/2915</a>
30BE_016C	Receive Descriptor Ring 2 Start Register (ENET1_RDSCR2)	32	R/W	0000_0000h	<a href="#">11.1.5.24/2916</a>
30BE_0170	Transmit Buffer Descriptor Ring 2 Start Register (ENET1_TDSR2)	32	R/W	0000_0000h	<a href="#">11.1.5.25/2916</a>
30BE_0174	Maximum Receive Buffer Size Register - Ring 2 (ENET1_MRBR2)	32	R/W	0000_0000h	<a href="#">11.1.5.26/2917</a>
30BE_0180	Receive Descriptor Ring 0 Start Register (ENET1_RDSCR)	32	R/W	0000_0000h	<a href="#">11.1.5.27/2918</a>

### 11.1.5.1 Interrupt Event Register (ENETx\_EIR)

When an event occurs that sets a bit in EIR, an interrupt occurs if the corresponding bit in the interrupt mask register (EIMR) is also set. Writing a 1 to an EIR bit clears it; writing 0 has no effect. This register is cleared upon hardware reset.

#### NOTE

TxBD[INT] and RxBD[INT] must be set to 1 to allow setting the corresponding EIR register flags in enhanced mode, ENET\_ECR[EN1588] = 1. Legacy mode does not require these flags to be enabled.

### ENETx\_EIR field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 BABR	Babbling Receive Error Indicates a frame was received with length in excess of RCR[MAX_FL] bytes.
2 BABT	Babbling Transmit Error Indicates the transmitted frame length exceeds RCR[MAX_FL] bytes. Usually this condition is caused when a frame that is too long is placed into the transmit data buffer(s). Truncation does not occur.
3 GRA	Graceful Stop Complete This interrupt is asserted after the transmitter is put into a pause state after completion of the frame currently being transmitted. See Graceful Transmit Stop (GTS) for conditions that lead to graceful stop. <b>NOTE:</b> The GRA interrupt is asserted only when the TX transitions into the stopped state. If this bit is cleared by writing 1 and the TX is still stopped, the bit is not set again.
4 TXF	Transmit Frame Interrupt Indicates a frame has been transmitted and the last corresponding buffer descriptor has been updated.
5 TXB	Transmit Buffer Interrupt Indicates a transmit buffer descriptor has been updated.
6 RXF	Receive Frame Interrupt Indicates a frame has been received and the last corresponding buffer descriptor has been updated.
7 RXB	Receive Buffer Interrupt Indicates a receive buffer descriptor is not the last in the frame has been updated.
8 MII	MII Interrupt. Indicates that the MII has completed the data transfer requested.
9 EBERR	Ethernet Bus Error Indicates a system bus error occurred when a uDMA transaction is underway. When this bit is set, ECR[ETHEREN] is cleared, halting frame processing by the MAC. When this occurs, software must ensure proper actions, possibly resetting the system, to resume normal operation.

Table continues on the next page...

## ENETx\_EIR field descriptions (continued)

Field	Description
10 LC	Late Collision  Indicates a collision occurred beyond the collision window (slot time) in half-duplex mode. The frame truncates with a bad CRC and the remainder of the frame is discarded.
11 RL	Collision Retry Limit  Indicates a collision occurred on each of 16 successive attempts to transmit the frame. The frame is discarded without being transmitted and transmission of the next frame commences. This error can only occur in half-duplex mode.
12 UN	Transmit FIFO Underrun  Indicates the transmit FIFO became empty before the complete frame was transmitted. A bad CRC is appended to the frame fragment and the remainder of the frame is discarded.
13 PLR	Payload Receive Error  Indicates a frame was received with a payload length error. See Frame Length/Type Verification: Payload Length Check for more information.
14 WAKEUP	Node Wakeup Request Indication  Read-only status bit to indicate that a magic packet has been detected. Will act only if ECR[MAGICEN] is set.
15 TS_AVAIL	Transmit Timestamp Available  Indicates that the timestamp of the last transmitted timing frame is available in the ATSTMP register.
16 TS_TIMER	Timestamp Timer  The adjustable timer reached the period event. A period event interrupt can be generated if ATCR[PEREN] is set and the timer wraps according to the periodic setting in the ATPER register. Set the timer period value before setting ATCR[PEREN].
17 RXFLUSH_2	RX DMA Ring 2 flush indication. This ring's RX frame has been flushed due to either RDAR2[RDAR] or RxBD[E] being clear and only if QOS[RXFLUSH_2] is enabled.
18 RXFLUSH_1	RX DMA Ring 1 flush indication. This ring's RX frame has been flushed due to either RDAR1[RDAR] or RxBD[E] being clear and only if QOS[RXFLUSH_1] is enabled.
19 RXFLUSH_0	RX DMA Ring 0 flush indication. . This ring's RX frame has been flushed due to either RDAR[RDAR] or RxBD[E] being clear and only if QOS[RXFLUSH_0] is enabled.
20–22 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
23 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
24 TXF2	Transmit frame interrupt, class 2  This bit indicates that a frame has been transmitted and the last corresponding buffer descriptor has been updated (ring/class 2).
25 TXB2	Transmit buffer interrupt, class 2  This field indicates that a transmit buffer descriptor has been updated (ring/class 2).
26 RXF2	Receive frame interrupt, class 2  This field indicates that a frame has been received and the last corresponding buffer descriptor has been updated (ring/class 2).

Table continues on the next page...

**ENETx\_EIR field descriptions (continued)**

Field	Description
27 RXB2	Receive buffer interrupt, class 2  This field indicates that a receive buffer descriptor, that not the last in the frame, has been updated (ring/class 2).
28 TXF1	Transmit frame interrupt, class 1  This bit indicates that a frame has been transmitted and the last corresponding buffer descriptor has been updated (ring/class 1).
29 TXB1	Transmit buffer interrupt, class 1  This field indicates that a transmit buffer descriptor has been updated (ring/class 1).
30 RXF1	Receive frame interrupt, class 1  This field indicates that a frame has been received and the last corresponding buffer descriptor has been updated (ring/class 1).
31 RXB1	Receive buffer interrupt, class 1  This field indicates that a receive buffer descriptor, that not the last in the frame, has been updated (ring/class 1).

**11.1.5.2 Interrupt Mask Register (ENETx\_EIMR)**

EIMR controls which interrupt events are allowed to generate actual interrupts. A hardware reset clears this register. If the corresponding bits in the EIR and EIMR registers are set, an interrupt is generated. The interrupt signal remains asserted until a 1 is written to the EIR field (write 1 to clear) or a 0 is written to the EIMR field.

## ENETx\_EIMR field descriptions

Field	Description
0 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
1 BABR	BABR Interrupt Mask  Corresponds to interrupt source EIR[BABR] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR BABR field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.  0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
2 BABT	BABT Interrupt Mask  Corresponds to interrupt source EIR[BABT] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR BABT field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.  0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
3 GRA	GRA Interrupt Mask  Corresponds to interrupt source EIR[GRA] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR GRA field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.  0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
4 TXF	TXF Interrupt Mask  Corresponds to interrupt source EIR[TXF] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TXF field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.  0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
5 TXB	TXB Interrupt Mask  Corresponds to interrupt source EIR[TXB] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TXF field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.  0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
6 RXF	RXF Interrupt Mask  Corresponds to interrupt source EIR[RXF] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR RXF field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.

*Table continues on the next page...*

## ENETx\_EIMR field descriptions (continued)

Field	Description
7 RXB	<p>RXB Interrupt Mask</p> <p>Corresponds to interrupt source EIR[RXB] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR RXB field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.</p>
8 MII	<p>MII Interrupt Mask</p> <p>Corresponds to interrupt source EIR[MII] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR MII field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.</p>
9 EBERR	<p>EBERR Interrupt Mask</p> <p>Corresponds to interrupt source EIR[EBERR] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR EBERR field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.</p>
10 LC	<p>LC Interrupt Mask</p> <p>Corresponds to interrupt source EIR[LC] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR LC field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.</p>
11 RL	<p>RL Interrupt Mask</p> <p>Corresponds to interrupt source EIR[RL] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR RL field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.</p>
12 UN	<p>UN Interrupt Mask</p> <p>Corresponds to interrupt source EIR[UN] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR UN field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.</p>
13 PLR	<p>PLR Interrupt Mask</p> <p>Corresponds to interrupt source EIR[PLR] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR PLR field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.</p>
14 WAKEUP	<p>WAKEUP Interrupt Mask</p> <p>Corresponds to interrupt source EIR[WAKEUP] register and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR WAKEUP field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.</p>
15 TS_AVAIL	<p>TS_AVAIL Interrupt Mask</p> <p>Corresponds to interrupt source EIR[TS_AVAIL] register and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting</p>

*Table continues on the next page...*

## ENETx\_EIMR field descriptions (continued)

Field	Description
	source. The corresponding EIR TS_AVAIL field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
16 TS_TIMER	TS_TIMER Interrupt Mask  Corresponds to interrupt source EIR[TS_TIMER] register and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TS_TIMER field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
17 RXFLUSH_2	Corresponds to interrupt source EIR[RXFLUSH_2] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[RXFLUSH_2] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
18 RXFLUSH_1	Corresponds to interrupt source EIR[RXFLUSH_1] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[RXFLUSH_1] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
19 RXFLUSH_0	Corresponds to interrupt source EIR[RXFLUSH_0] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[RXFLUSH_0] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
20–22 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
23 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
24 TXF2	Transmit frame interrupt, class 2  Corresponds to interrupt source EIR[TXF2] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[TXF2] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
25 TXB2	Transmit buffer interrupt, class 2  Corresponds to interrupt source EIR[TXB2] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[TXB2] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
26 RXF2	Receive frame interrupt, class 2  Corresponds to interrupt source EIR[RXF2] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[RXF2] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
27 RXB2	Receive buffer interrupt, class 2  Corresponds to interrupt source EIR[RXB2] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[RXB2] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
28 TXF1	Transmit frame interrupt, class 1  Corresponds to interrupt source EIR[TXF1] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[TXF1] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
29 TXB1	Transmit buffer interrupt, class 1

*Table continues on the next page...*

**ENETx\_EIMR field descriptions (continued)**

Field	Description
	Corresponds to interrupt source EIR[TXB1] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[TXB1] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
30 RXF1	Receive frame interrupt, class 1  Corresponds to interrupt source EIR[RXF1] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[RXF1] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
31 RXB1	Receive buffer interrupt, class 1  Corresponds to interrupt source EIR[RXB1] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[RXB1] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.

**11.1.5.3 Receive Descriptor Active Register - Ring 0 (ENETx\_RDAR)**

RDAR is a command register, written by the user, to indicate that the receive descriptor ring 0 has been updated, that is, that the driver produced empty receive buffers with the empty bit set.

Address: Base address + 10h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	
R	0							RDAR	0								
W	[Shaded]								[Shaded]								
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31	
R	0																
W	[Shaded]																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

**ENETx\_RDAR field descriptions**

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 RDAR	Receive Descriptor Active

*Table continues on the next page...*

## ENETx\_RDAR field descriptions (continued)

Field	Description
	Always set to 1 when this register is written, regardless of the value written. This field is cleared by the MAC device when no additional empty descriptors remain in the receive ring. It is also cleared when ECR[ETHEREN] transitions from set to cleared or when ECR[RESET] is set.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

## 11.1.5.4 Transmit Descriptor Active Register - Ring 0 (ENETx\_TDAR)

The TDAR is a command register that the user writes to indicate that the transmit descriptor ring 0 has been updated, that is, that transmit buffers have been produced by the driver with the ready bit set in the buffer descriptor.

The TDAR register is cleared at reset, when ECR[ETHEREN] transitions from set to cleared, or when ECR[RESET] is set.

Address: Base address + 14h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	
R	0							TDAR	0								
W	[Shaded]								[Shaded]								
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31	
R	0																
W	[Shaded]																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

## ENETx\_TDAR field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 TDAR	Transmit Descriptor Active  Always set to 1 when this register is written, regardless of the value written. This bit is cleared by the MAC device when no additional ready descriptors remain in the transmit ring. Also cleared when ECR[ETHEREN] transitions from set to cleared or when ECR[RESET] is set.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

### 11.1.5.5 Ethernet Control Register (ENETx\_ECR)

ECR is a read/write user register, though hardware may also alter fields in this register. It controls many of the high level features of the Ethernet MAC, including legacy FEC support through the EN1588 field.

Address: Base address + 24h offset

**ENETx\_ECR field descriptions**

Field	Description
0–13 Reserved	This field is reserved. This field must be set to 0111000000000b.
14–19 Reserved	This field is reserved. This field must be set to 0.
20 SVLANDBL	S-VLAN double tag  If enabled, S-VLAN detection requires a double-tagged frame to define a frame as being a VLAN frame. The following rules apply: <ul style="list-style-type: none"> <li>• If the first tag is the S-VLAN type, it must be followed by a second tag with the C-VLAN type to declare the frame as VLAN frame.</li> <li>• If the first tag is the S-VLAN type but no 2nd tag follows, it is not considered a VLAN frame but instead treated as an untagged frame.</li> <li>• If the first tag is the C-VLAN type, it is considered a VLAN frame as normal.</li> </ul>

*Table continues on the next page...*

## ENETx\_ECR field descriptions (continued)

Field	Description
	<b>NOTE:</b> VLANUSE2ND can be used to determine from which tag the data should be extracted. This applies only if SVLAN_EN = 1, ignored otherwise.
21 VLANUSE2ND	VLAN use second tag  0 Always extract data from the first VLAN tag if it exists. 1 When a double-tagged frame is detected, the data of the second tag is extracted for further processing. A double-tagged frame is defined as: <ul style="list-style-type: none"> <li>• The first tag can be a C-VLAN or a S-VLAN (if SVLAN_ENA = 1)</li> <li>• The second tag must be a C-VLAN</li> </ul>
22 SVLANEN	S-VLAN enable  Enable additional detection of S-VLAN tag according to IEEE802.1Q.  0 Only the EtherType 0x8100 will be considered for VLAN detection. 1 The EtherType 0x88a8 will be considered in addition to 0x8100 (C-VLAN) to identify a VLAN frame in receive. When a VLAN frame is identified, the two bytes following the VLAN type are extracted and used by the classification match comparators, RCMRn.
23 DBSWP	Descriptor Byte Swapping Enable  Swaps the byte locations of the buffer descriptors.  <b>NOTE:</b> This field must be written to 1 after reset.  0 The buffer descriptor bytes are not swapped to support big-endian devices. 1 The buffer descriptor bytes are swapped to support little-endian devices.
24 Reserved	This field is reserved. This field must be set to zero.
25 DBGEN	Debug Enable  Enables the MAC to enter hardware freeze mode when the device enters debug mode.  0 MAC continues operation in debug mode. 1 MAC enters hardware freeze mode when the processor is in debug mode.
26 SPEED	Selects between 10/100-Mbit/s and 1000-Mbit/s modes of operation.  0 10/100-Mbit/s mode 1 1000-Mbit/s mode
27 EN1588	EN1588 Enable  Enables enhanced functionality of the MAC.  0 Legacy FEC buffer descriptors and functions enabled. 1 Enhanced frame time-stamping functions enabled.
28 SLEEP	Sleep Mode Enable  0 Normal operating mode. 1 Sleep mode.
29 MAGICEN	Magic Packet Detection Enable  Enables/disables magic packet detection.

*Table continues on the next page...*

**ENETx\_ECR field descriptions (continued)**

Field	Description
	<p><b>NOTE:</b> MAGICEN is relevant only if the SLEEP field is set. If MAGICEN is set, changing the SLEEP field enables/disables sleep mode and magic packet detection.</p> <p>0 Magic detection logic disabled.                      1 The MAC core detects magic packets and asserts EIR[WAKEUP] when a frame is detected.</p>
30 ETHEREN	<p>Ethernet Enable</p> <p>Enables/disables the Ethernet MAC. When the MAC is disabled, the buffer descriptors for an aborted transmit frame are not updated. The uDMA, buffer descriptor, and FIFO control logic are reset, including the buffer descriptor and FIFO pointers.</p> <p>Hardware clears this field under the following conditions:</p> <ul style="list-style-type: none"> <li>• RESET is set by software</li> <li>• An error condition causes the EBERR field to set.</li> </ul> <p><b>NOTE:</b></p> <ul style="list-style-type: none"> <li>• ETHEREN must be set at the very last step during ENET configuration/setup/initialization, only <i>after</i> all other ENET-related registers have been configured.</li> <li>• If ETHEREN is cleared to 0 by software then next time ETHEREN is set, the EIR interrupts must cleared to 0 due to previous pending interrupts.</li> </ul> <p>0 Reception immediately stops and transmission stops after a bad CRC is appended to any currently transmitted frame.                      1 MAC is enabled, and reception and transmission are possible.</p>
31 RESET	<p>Ethernet MAC Reset</p> <p>When this field is set, it clears the ETHEREN field.</p>

**11.1.5.6 MII Management Frame Register (ENETx\_MMFR)**

Writing to MMFR triggers a management frame transaction to the PHY device unless MSCR is programmed to zero.

If MSCR is changed from zero to non-zero during a write to MMFR, an MII frame is generated with the data previously written to the MMFR. This allows MMFR and MSCR to be programmed in either order if MSCR is currently zero.

If the MMFR register is written while frame generation is in progress, the frame contents are altered. Software must use the EIR[MII] interrupt indication to avoid writing to the MMFR register while frame generation is in progress.

Address: Base address + 40h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R																																
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### ENETx\_MMFR field descriptions

Field	Description
0–1 ST	Start Of Frame Delimiter See <a href="#">Table 11-42</a> (Clause 22) or <a href="#">Table 11-44</a> (Clause 45) for correct value.
2–3 OP	Operation Code See <a href="#">Table 11-42</a> (Clause 22) or <a href="#">Table 11-44</a> (Clause 45) for correct value.
4–8 PA	PHY Address See <a href="#">Table 11-42</a> (Clause 22) or <a href="#">Table 11-44</a> (Clause 45) for correct value.
9–13 RA	Register Address See <a href="#">Table 11-42</a> (Clause 22) or <a href="#">Table 11-44</a> (Clause 45) for correct value.
14–15 TA	Turn Around This field must be programmed to 10 to generate a valid MII management frame.
16–31 DATA	Management Frame Data This is the field for data to be written to or read from the PHY register.

#### 11.1.5.7 MII Speed Control Register (ENETx\_MSCR)

MSCR provides control of the MII clock (MDC pin) frequency and allows a preamble drop on the MII management frame.

The MII\_SPEED field must be programmed with a value to provide an MDC frequency of less than or equal to 2.5 MHz to be compliant with the IEEE 802.3 MII specification. The MII\_SPEED must be set to a non-zero value to source a read or write management frame. After the management frame is complete, the MSCR register may optionally be cleared to turn off MDC. The MDC signal generated has a 50% duty cycle except when MII\_SPEED changes during operation. This change takes effect following a rising or falling edge of MDC.

For example, if the internal module clock (i.e., IPS bus clock) is 25 MHz, programming MII\_SPEED to 0x4 results in an MDC as given in the following equation:

$$\text{MII clock frequency} = 25 \text{ MHz} / ((4 + 1) \times 2) = 2.5 \text{ MHz}$$

The following table shows the optimum values for MII\_SPEED as a function of IPS bus clock frequency.

**Table 11-4. Programming Examples for MSCR**

Internal module clock frequency	MSCR [MII_SPEED]	MDC frequency
25 MHz	0x4	2.50 MHz

*Table continues on the next page...*

**Table 11-4. Programming Examples for MSCR (continued)**

Internal module clock frequency	MSCR [MII_SPEED]	MDC frequency
33 MHz	0x6	2.36 MHz
40 MHz	0x7	2.50 MHz
50 MHz	0x9	2.50 MHz
66 MHz	0xD	2.36 MHz

Address: Base address + 44h offset

Bit	0	1	2	3	4	5	6	7		8	9	10	11	12	13	14	15	
R	0																	
W																		
Reset	0	0	0	0	0	0	0	0		0	0	0	0	0	0	0	0	0
Bit	16	17	18	19	20	21	22	23		24	25	26	27	28	29	30	31	
R	0					HOLDTIME			DIS_	MII_SPEED						0		
W									PRE									
Reset	0	0	0	0	0	0	0	0		0	0	0	0	0	0	0	0	0

**ENETx\_MSCR field descriptions**

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–23 HOLDTIME	Hold time On MDIO Output  IEEE802.3 clause 22 defines a minimum of 10 ns for the hold time on the MDIO output. Depending on the host bus frequency, the setting may need to be increased.  000 1 internal module clock cycle 001 2 internal module clock cycles 010 3 internal module clock cycles 111 8 internal module clock cycles
24 DIS_PRE	Disable Preamble  Enables/disables prepending a preamble to the MII management frame. The MII standard allows the preamble to be dropped if the attached PHY devices do not require it.  0 Preamble enabled. 1 Preamble (32 ones) is not prepended to the MII management frame.
25–30 MII_SPEED	MII Speed  Controls the frequency of the MII management interface clock (MDC) relative to the internal module clock. A value of 0 in this field turns off MDC and leaves it in low voltage state. Any non-zero value results in the MDC frequency of:  $1/((MII\_SPEED + 1) \times 2)$ of the internal module clock frequency
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

### 11.1.5.8 MIB Control Register (ENETx\_MIBC)

MIBC is a read/write register controlling and observing the state of the MIB block. Access this register to disable the MIB block operation or clear the MIB counters. The MIB\_DIS field resets to 1.

Address: Base address + 64h offset

**ENETx\_MIBC field descriptions**

Field	Description
0 MIB_DIS	Disable MIB Logic If this control field is set, 0 MIB logic is enabled. 1 MIB logic is disabled. The MIB logic halts and does not update any MIB counters.
1 MIB_IDLE	MIB Idle

*Table continues on the next page...*

### ENETx\_MIBC field descriptions (continued)

Field	Description
	0 The MIB block is updating MIB counters. 1 The MIB block is not currently updating any MIB counters.
2 MIB_CLEAR	MIB Clear  <b>NOTE:</b> This field is not self-clearing. To clear the MIB counters set and then clear this field.  0 See note above. 1 All statistics counters are reset to 0.
3–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

### 11.1.5.9 Receive Control Register (ENETx\_RCR)

Address: Base address + 84h offset

## ENETx\_RCR field descriptions

Field	Description
0 GRS	Graceful Receive Stopped Read-only status indicating that the MAC receive datapath is stopped.
1 NLC	Payload Length Check Disable Enables/disables a payload length check. 0 The payload length check is disabled. 1 The core checks the frame's payload length with the frame length/type field. Errors are indicated in the EIR[PLC] field.
2–15 MAX_FL	Maximum Frame Length Resets to decimal 1518. Length is measured starting at DA and includes the CRC at the end of the frame. Transmit frames longer than MAX_FL cause the BABT interrupt to occur. Receive frames longer than MAX_FL cause the BABR interrupt to occur and set the LG field in the end of frame receive buffer descriptor. The recommended default value to be programmed is 1518 or 1522 if VLAN tags are supported.
16 CFEN	MAC Control Frame Enable Enables/disables the MAC control frame. 0 MAC control frames with any opcode other than 0x0001 (pause frame) are accepted and forwarded to the client interface. 1 MAC control frames with any opcode other than 0x0001 (pause frame) are silently discarded.
17 CRCFWD	Terminate/Forward Received CRC Specifies whether the CRC field of received frames is transmitted or stripped. <b>NOTE:</b> If padding function is enabled (PADEN = 1), CRCFWD is ignored and the CRC field is checked and always terminated and removed. 0 The CRC field of received frames is transmitted to the user application. 1 The CRC field is stripped from the frame.
18 PAUFWD	Terminate/Forward Pause Frames Specifies whether pause frames are terminated or forwarded. 0 Pause frames are terminated and discarded in the MAC. 1 Pause frames are forwarded to the user application.
19 PADEN	Enable Frame Padding Remove On Receive Specifies whether the MAC removes padding from received frames. 0 No padding is removed on receive by the MAC. 1 Padding is removed from received frames.
20–21 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
22 RMII_10T	Enables 10-Mbit/s mode of the RMII or RGMII . 0 100-Mbit/s operation. 1 10-Mbit/s operation.

Table continues on the next page...

## ENETx\_RCR field descriptions (continued)

Field	Description
23 RMII_MODE	<p>RMII Mode Enable</p> <p>Specifies whether the MAC is configured for MII mode or RMII operation , when ECR[SPEED] is cleared .</p> <p><b>NOTE:</b> Do not set both RCR[RGMIEN] and RCR[RMII_MODE].</p> <p>0 MAC configured for MII mode. 1 MAC configured for RMII operation.</p>
24 Reserved	<p>This field is reserved.</p> <p>This write-only field is reserved. It must always be written with the value 0.</p>
25 RGMII_EN	<p>RGMII Mode Enable</p> <p><b>NOTE:</b> Do not set both RCR[RGMIEN] and RCR[RMII_MODE].</p> <p>0 MAC configured for non-RGMII operation 1 MAC configured for RGMII operation. If ECR[SPEED] is set, the MAC is in RGMII 1000-Mbit/s mode. If ECR[SPEED] is cleared, the MAC is in RGMII 10/100-Mbit/s mode.</p>
26 FCE	<p>Flow Control Enable</p> <p>If set, the receiver detects PAUSE frames. Upon PAUSE frame detection, the transmitter stops transmitting data frames for a given duration.</p>
27 BC_REJ	<p>Broadcast Frame Reject</p> <p>If set, frames with destination address (DA) equal to 0xFFFF_FFFF_FFFF are rejected unless the PROM field is set. If BC_REJ and PROM are set, frames with broadcast DA are accepted and the MISS (M) is set in the receive buffer descriptor.</p>
28 PROM	<p>Promiscuous Mode</p> <p>All frames are accepted regardless of address matching.</p> <p>0 Disabled. 1 Enabled.</p>
29 MII_MODE	<p>Media Independent Interface Mode</p> <p>This field must always be set.</p> <p>0 Reserved. 1 MII or RMII mode, as indicated by the RMII_MODE field.</p>
30 DRT	<p>Disable Receive On Transmit</p> <p>0 Receive path operates independently of transmit (i.e., full-duplex mode). Can also be used to monitor transmit activity in half-duplex mode. 1 Disable reception of frames while transmitting. (Normally used for half-duplex mode.)</p>
31 LOOP	<p>Internal Loopback</p> <p>This is an MII internal loopback, therefore MII_MODE must be written to 1 and RMII_MODE must be written to 0.</p> <p>0 Loopback disabled. 1 Transmitted frames are looped back internal to the device and transmit MII output signals are not asserted. DRT must be cleared.</p>

### 11.1.5.10 Transmit Control Register (ENETx\_TCR)

TCR is read/write and configures the transmit block. This register is cleared at system reset. FDEN can only be modified when ECR[ETHEREN] is cleared.

Address: Base address + C4h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	
R	0																
W	[Shaded]																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	
Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31	
R	0					Reserved	CRCFWD	ADDINS	ADDSEL				RFC_PAUSE	TFC_PAUSE	FDEN	[Shaded]	GTS
W	[Shaded]											[Shaded]			0		
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

**ENETx\_TCR field descriptions**

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 Reserved	This field is reserved. This field is read/write and must be set to 0.
22 CRCFWD	Forward Frame From Application With CRC 0 TxBD[TC] controls whether the frame has a CRC from the application. 1 The transmitter does not append any CRC to transmitted frames, as it is expecting a frame with CRC from the application.

*Table continues on the next page...*

## ENETx\_TCR field descriptions (continued)

Field	Description
23 ADDINS	Set MAC Address On Transmit  0 The source MAC address is not modified by the MAC. 1 The MAC overwrites the source MAC address with the programmed MAC address according to ADDSEL.
24–26 ADDSEL	Source MAC Address Select On Transmit  If ADDINS is set, indicates the MAC address that overwrites the source MAC address.  000 Node MAC address programmed on PADDR1/2 registers. 100 Reserved. 101 Reserved. 110 Reserved.
27 RFC_PAUSE	Receive Frame Control Pause  This status field is set when a full-duplex flow control pause frame is received and the transmitter pauses for the duration defined in this pause frame. This field automatically clears when the pause duration is complete.
28 TFC_PAUSE	Transmit Frame Control Pause  Pauses frame transmission. When this field is set, EIR[GRA] is set. With transmission of data frames stopped, the MAC transmits a MAC control PAUSE frame. Next, the MAC clears TFC_PAUSE and resumes transmitting data frames. If the transmitter pauses due to user assertion of GTS or reception of a PAUSE frame, the MAC may continue transmitting a MAC control PAUSE frame.  0 No PAUSE frame transmitted. 1 The MAC stops transmission of data frames after the current transmission is complete.
29 FDEN	Full-Duplex Enable  If this field is set, frames transmit independent of carrier sense and collision inputs. Only modify this bit when ECR[ETHEREN] is cleared.
30 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
31 GTS	Graceful Transmit Stop  When this field is set, MAC stops transmission after any frame currently transmitted is complete and EIR[GRA] is set. If frame transmission is not currently underway, the GRA interrupt is asserted immediately. After transmission finishes, clear GTS to restart. The next frame in the transmit FIFO is then transmitted. If an early collision occurs during transmission when GTS is set, transmission stops after the collision. The frame is transmitted again after GTS is cleared. There may be old frames in the transmit FIFO that transmit when GTS is reasserted. To avoid this, clear ECR[ETHEREN] following the GRA interrupt.

### 11.1.5.11 Physical Address Lower Register (ENETx\_PALR)

PALR contains the lower 32 bits (bytes 0, 1, 2, 3) of the 48-bit address used in the address recognition process to compare with the destination address (DA) field of receive frames with an individual DA. In addition, this register is used in bytes 0 through 3 of the six-byte source address field when transmitting PAUSE frames.

Address: Base address + E4h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	PADDR1																															
W	PADDR1																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ENETx\_PALR field descriptions

Field	Description
0–31 PADDR1	Pause Address  Bytes 0 (bits 31:24), 1 (bits 23:16), 2 (bits 15:8), and 3 (bits 7:0) of the 6-byte individual address are used for exact match and the source address field in PAUSE frames.

### 11.1.5.12 Physical Address Upper Register (ENETx\_PAUR)

PAUR contains the upper 16 bits (bytes 4 and 5) of the 48-bit address used in the address recognition process to compare with the destination address (DA) field of receive frames with an individual DA. In addition, this register is used in bytes 4 and 5 of the six-byte source address field when transmitting PAUSE frames. Bits 15:0 of PAUR contain a constant type field (0x8808) for transmission of PAUSE frames.

Address: Base address + E8h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	PADDR2																TYPE															
W	PADDR2																TYPE															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	1	0	0	0	0	0	0	0	1	0	0	0

#### ENETx\_PAUR field descriptions

Field	Description
0–15 PADDR2	Bytes 4 (bits 31:24) and 5 (bits 23:16) of the 6-byte individual address used for exact match, and the source address field in PAUSE frames.
16–31 TYPE	Type Field In PAUSE Frames  These fields have a constant value of 0x8808.

### 11.1.5.13 Opcode/Pause Duration Register (ENETx\_OPD)

OPD is read/write accessible. This register contains the 16-bit opcode and 16-bit pause duration fields used in transmission of a PAUSE frame. The opcode field is a constant value, 0x0001. When another node detects a PAUSE frame, that node pauses transmission for the duration specified in the pause duration field. The lower 16 bits of this register are not reset and you must initialize it.

Address: Base address + ECh offset

#### ENETx\_OPD field descriptions

Field	Description
0–15 OPCODE	Opcode Field In PAUSE Frames These fields have a constant value of 0x0001.
16–31 PAUSE_DUR	Pause Duration Pause duration field used in PAUSE frames.

### 11.1.5.14 Transmit Interrupt Coalescing Register (ENETx\_TXICn)

See [Interrupt coalescence](#) for more information.

Address: Base address + F0h offset + (4d × i), where i=0d to 2d

#### ENETx\_TXICn field descriptions

Field	Description
0 ICEN	Interrupt Coalescing Enable

Table continues on the next page...

## ENETx\_TXICn field descriptions (continued)

Field	Description
	0 Disable Interrupt coalescing. 1 Enable Interrupt coalescing.
1 ICCS	Interrupt Coalescing Timer Clock Source Select 0 Use MII/GMII TX clocks. 1 Use ENET system clock.
2–3 Reserved	This field must be set to 0.  This field is reserved.
4–11 ICFT	Interrupt coalescing frame count threshold  This value determines the number of frames needed to be transmitted for raising an interrupt. Frame counter restarts after reaching this threshold value or after the expiring of the coalescing timer. Must be greater than zero to avoid unpredictable behavior.
12–15 Reserved	This field must be set to 0.  This field is reserved.
16–31 ICTT	Interrupt coalescing timer threshold  Interrupt coalescing timer threshold in units of 64 clock periods. This value determines the maximum amount of time after transmitting a frame before raising an interrupt. The threshold timer is disabled after expiring or number of frame transmission defined by ICFT and starts again upon transmission of the next first frame. Must be greater than zero to avoid unpredictable behavior.

## 11.1.5.15 Receive Interrupt Coalescing Register (ENETx\_RXICn)

See [Interrupt coalescence](#) for more information.

Address: Base address + 100h offset + (4d × i), where i=0d to 2d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

## ENETx\_RXICn field descriptions

Field	Description
0 ICEN	Interrupt Coalescing Enable 0 Disable Interrupt coalescing. 1 Enable Interrupt coalescing.

Table continues on the next page...

**ENETx\_RXICn field descriptions (continued)**

Field	Description
1 ICCS	Interrupt Coalescing Timer Clock Source Select  0 Use MII/GMII TX clocks. 1 Use ENET system clock.
2-3 Reserved	This field must be set to 0.  This field is reserved.
4-11 ICFT	Interrupt coalescing frame count threshold  This value determines the number of frames needed to be received for raising an interrupt. Frame counter restarts after reaching this threshold value or after the expiring of the coalescing timer. Must be greater than zero to avoid unpredictable behavior.
12-15 Reserved	This field must be set to 0.  This field is reserved.
16-31 ICTT	Interrupt coalescing timer threshold  Interrupt coalescing timer threshold in units of 64 clock periods. This value determines the maximum amount of time after receiving a frame before raising an interrupt. The threshold timer is disabled after expiring or number of frame reception defined by ICFT and starts again upon reception of the next first frame. Must be greater than zero to avoid unpredictable behavior.

**11.1.5.16 Descriptor Individual Upper Address Register (ENETx\_IAUR)**

IAUR contains the upper 32 bits of the 64-bit individual address hash table. The address recognition process uses this table to check for a possible match with the destination address (DA) field of receive frames with an individual DA. This register is not reset and you must initialize it.

Address: Base address + 118h offset

**ENETx\_IAUR field descriptions**

Field	Description
0-31 IADDR1	Contains the upper 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a unicast address. Bit 31 of IADDR1 contains hash index bit 63. Bit 0 of IADDR1 contains hash index bit 32.

### 11.1.5.17 Descriptor Individual Lower Address Register (ENETx\_IALR)

IALR contains the lower 32 bits of the 64-bit individual address hash table. The address recognition process uses this table to check for a possible match with the DA field of receive frames with an individual DA. This register is not reset and you must initialize it.

Address: Base address + 11Ch offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ENETx\_GAUR field descriptions

Field	Description
0–31 GADDR1	Contains the upper 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. Bit 31 of GADDR1 contains hash index bit 63. Bit 0 of GADDR1 contains hash index bit 32.

### 11.1.5.19 Descriptor Group Lower Address Register (ENETx\_GALR)

GALR contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. You must initialize this register.

Address: Base address + 124h offset

#### ENETx\_GALR field descriptions

Field	Description
0–31 GADDR2	Contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. Bit 31 of GADDR2 contains hash index bit 31. Bit 0 of GADDR2 contains hash index bit 0.

### 11.1.5.20 Transmit FIFO Watermark Register (ENETx\_TFWR)

If TFWR[STRFWD] is cleared, TFWR[TFWR] controls the amount of data required in the transmit FIFO before transmission of a frame can begin. This allows you to minimize transmit latency (TFWR = 00 or 01) or allow for larger bus access latency (TFWR = 11) due to contention for the system bus. Setting the watermark to a high value minimizes the risk of transmit FIFO underrun due to contention for the system bus. The byte counts associated with the TFWR field may need to be modified to match a given system requirement, for example, worst-case bus access latency by the transmit data uDMA channel.

When the FIFO level reaches the value the TFWR field and when the STR\_FWD is set to '0', the MAC transmit control logic starts frame transmission even before the end-of-frame is available in the FIFO (cut-through operation).

If a complete frame has a size smaller than the threshold programmed with TFWR, the MAC also transmits the Frame to the line.

To enable store and forward on the Transmit path, set STR\_FWD to '1'. In this case, the MAC starts to transmit data only when a complete frame is stored in the Transmit FIFO.

Address: Base address + 144h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	
R	0																
W																	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**ENETx\_TFWR field descriptions**

Field	Description
0–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 STRFWD	Store And Forward Enable 0 Reset. The transmission start threshold is programmed in TFWR[TFWR]. 1 Enabled.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 TFWR	Transmit FIFO Write If TFWR[STRFWD] is cleared, this field indicates the number of bytes, in steps of 64 bytes, written to the transmit FIFO before transmission of a frame begins. <b>NOTE:</b> If a frame with less than the threshold is written, it is still sent independently of this threshold setting. The threshold is relevant only if the frame is larger than the threshold given.  000000 64 bytes written. 000001 64 bytes written. 000010 128 bytes written. 000011 192 bytes written. ... .. 111111 4032 bytes written.

**11.1.5.21 Receive Descriptor Ring 1 Start Register (ENETx\_RDSR1)**

RDSR1 points to the beginning of circular receive buffer descriptor queue 1 in external memory. This pointer must be 64-bit aligned (bits 29–31 must be zero); however, for optimal performance the pointer should be 512-bit aligned, that is, evenly divisible by 64.

**NOTE**

This register must be initialized prior to operation.

## Ethernet MAC (ENET)

Address: Base address + 160h offset

30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

#### 11.1.5.23 Maximum Receive Buffer Size Register - Ring 1 (ENETx\_MRBR1)

MRBR1 is a user-programmable register that dictates the maximum size of all ring-1 receive buffers. This value should take into consideration that the receive CRC is always written into the last receive buffer.

- To allow one maximum size frame per buffer, MRBR1 must be set to RCR[MAX\_FL] or larger.
- R\_BUF\_SIZE is concatenated with the four least-significant bits of this register and are used as the maximum receive buffer size.
- To properly align the buffer, MRBR1 must be evenly divisible by 64. To ensure this, set the lower two bits of R\_BUF\_SIZE to zero. The lower four bits are already set to zero by the device.
- To minimize bus usage (descriptor fetches), set MRBR1 greater than or equal to 256 bytes.

#### NOTE

This register must be initialized before operation.

Address: Base address + 168h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

#### ENETx\_RSEM field descriptions

Field	Description
0–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–15 STAT_SECTION_EMPTY	RX Status FIFO Section Empty Threshold Defines number of frames in the receive FIFO, independent of its size, that can be accepted. If the limit is reached, reception will continue normally, however a pause frame will be triggered to indicate a possible congestion to the remote device to avoid FIFO overflow. A value of 0 disables automatic pause frame generation
16–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–31 RX_SECTION_EMPTY	Value Of The Receive FIFO Section Empty Threshold Value, in 64-bit words, of the receive FIFO section empty threshold. When the FIFO has reached this level, a pause frame will be issued. A value of 0 disables automatic pause frame generation. When the FIFO level goes below the value programmed in this field, an XON pause frame is issued to indicate the FIFO congestion is cleared to the remote Ethernet client. <b>NOTE:</b> The section-empty threshold indications from both FIFOs are OR'ed to cause XOFF pause frame generation.

### 11.1.5.32 Receive FIFO Almost Empty Threshold (ENETx\_RAEM)

Address: Base address + 198h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31	
R	0																					RX_ALMOST_EMPTY											
W	█																					█											
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0

#### ENETx\_RAEM field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

### ENETx\_RAEM field descriptions (continued)

Field	Description
22–31 RX_ALMOST_EMPTY	Value Of The Receive FIFO Almost Empty Threshold  Value, in 64-bit words, of the receive FIFO almost empty threshold. When the FIFO level reaches the value programmed in this field and the end-of-frame has not been received for the frame yet, the core receive read control stops FIFO read (and subsequently stops transferring data to the MAC client application). It continues to deliver the frame, if again more data than the threshold or the end-of-frame is available in the FIFO. A minimum value of 4 should be set.

### 11.1.5.33 Receive FIFO Almost Full Threshold (ENETx\_RAFL)

Address: Base address + 19Ch offset

#### ENETx\_RAFL field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–31 RX_ALMOST_FULL	Value Of The Receive FIFO Almost Full Threshold  Value, in 64-bit words, of the receive FIFO almost full threshold. When the FIFO level comes close to the maximum, so that there is no more space for at least RX_ALMOST_FULL number of words, the MAC stops writing data in the FIFO and truncates the received frame to avoid FIFO overflow. The corresponding error status will be set when the frame is delivered to the application. A minimum value of 4 should be set.

### 11.1.5.34 Transmit FIFO Section Empty Threshold (ENETx\_TSEM)

Address: Base address + 1A0h offset

#### ENETx\_TSEM field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–31 TX_SECTION_EMPTY	Value Of The Transmit FIFO Section Empty Threshold  Value, in 64-bit words, of the transmit FIFO section empty threshold. See <a href="#">Transmit FIFO</a> for more information.

### 11.1.5.35 Transmit FIFO Almost Empty Threshold (ENETx\_TAEM)

Address: Base address + 1A4h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0															TX_ALMOST_EMPTY																
W	0																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0

#### ENETx\_TAEM field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–31 TX_ALMOST_EMPTY	Value of Transmit FIFO Almost Empty Threshold Value, in 64-bit words, of the transmit FIFO almost empty threshold. When the FIFO level reaches the value programmed in this field, and no end-of-frame is available for the frame, the MAC transmit logic, to avoid FIFO underflow, stops reading the FIFO and transmits a frame with an MII error indication. See <a href="#">Transmit FIFO</a> for more information. A minimum value of 4 should be set.

### 11.1.5.36 Transmit FIFO Almost Full Threshold (ENETx\_TAFL)

Address: Base address + 1A8h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0															TX_ALMOST_FULL																
W	0																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0

#### ENETx\_TAFL field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–31 TX_ALMOST_FULL	Value Of The Transmit FIFO Almost Full Threshold Value, in 64-bit words, of the transmit FIFO almost full threshold. A minimum value of six is required . A recommended value of at least 8 should be set allowing a latency of two clock cycles to the application. If more latency is required the value can be increased as necessary (latency = TAFL - 5). When the FIFO level comes close to the maximum, so that there is no more space for at least TX_ALMOST_FULL number of words, the pin ff_tx_rdy is deasserted. If the application does not react on this signal, the FIFO write control logic, to avoid FIFO overflow, truncates the current frame and sets the error status. As a result, the frame will be transmitted with an GMII/MII error indication. See <a href="#">Transmit FIFO</a> for more information. <b>NOTE:</b> A FIFO overflow is a fatal error and requires a global reset on the transmit datapath or at least deassertion of ETHEREN.

### 11.1.5.37 Transmit Inter-Packet Gap (ENETx\_TIPG)

Address: Base address + 1ACh offset

#### ENETx\_TIPG field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 IPG	Transmit Inter-Packet Gap  Indicates the IPG, in bytes, between transmitted frames. Valid values range from 8 to 26. If the written value is less than 8 or greater than 26, the internal (effective) IPG is 12.  <b>NOTE:</b> The IPG value read will be the value that was written, even if it is out of range.

### 11.1.5.38 Frame Truncation Length (ENETx\_FTRL)

Address: Base address + 1B0h offset

#### ENETx\_FTRL field descriptions

Field	Description
0–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–31 TRUNC_FL	Frame Truncation Length  Indicates the value a receive frame is truncated, if it is greater than this value. Must be greater than or equal to RCR[MAX_FL].  <b>NOTE:</b> Truncation happens at TRUNC_FL. However, when truncation occurs, the application (FIFO) may receive less data, guaranteeing that it never receives more than the set limit.

### 11.1.5.39 Transmit Accelerator Function Configuration (ENETx\_TACC)

TACC controls accelerator actions when sending frames. The register can be changed before or after each frame, but it must remain unmodified during frame writes into the transmit FIFO.

The TFWR[STRFWD] field must be set to use the checksum feature.

Address: Base address + 1C0h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	[Reserved]															
W	0															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	[Reserved]											PROCHK	IPCHK	[Reserved]		SHIFT16
W	0											PROCHK	IPCHK	0	SHIFT16	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ENETx\_TACC field descriptions

Field	Description
0–26 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
27 PROCHK	Enables insertion of protocol checksum. 0 Checksum not inserted. 1 If an IP frame with a known protocol is transmitted, the checksum is inserted automatically into the frame. The checksum field must be cleared. The other frames are not modified.
28 IPCHK	Enables insertion of IP header checksum. 0 Checksum is not inserted. 1 If an IP frame is transmitted, the checksum is inserted automatically. The IP header checksum field must be cleared. If a non-IP frame is transmitted the frame is not modified.
29–30 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
31 SHIFT16	TX FIFO Shift-16 0 Disabled. 1 Indicates to the transmit data FIFO that the written frames contain two additional octets before the frame data. This means the actual frame begins at bit 16 of the first word written into the FIFO. This function allows putting the frame payload on a 32-bit boundary in memory, as the 14-byte Ethernet header is extended to a 16-byte header.

### 11.1.5.40 Receive Accelerator Function Configuration (ENETx\_RACC)

Address: Base address + 1C4h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R																
W	0															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R									SHIFT16	LINEDIS				PRODIS	IPDIS	PADREM
W	0								SHIFT16	LINEDIS	0			PRODIS	IPDIS	PADREM
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ENETx\_RACC field descriptions

Field	Description
0–23 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
24 SHIFT16	RX FIFO Shift-16 When this field is set, the actual frame data starts at bit 16 of the first word read from the RX FIFO aligning the Ethernet payload on a 32-bit boundary. <b>NOTE:</b> This function only affects the FIFO storage and has no influence on the statistics, which use the actual length of the frame received. 0 Disabled. 1 Instructs the MAC to write two additional bytes in front of each frame received into the RX FIFO.
25 LINEDIS	Enable Discard Of Frames With MAC Layer Errors 0 Frames with errors are not discarded. 1 Any frame received with a CRC, length, or PHY error is automatically discarded and not forwarded to the user application interface.
26–28 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
29 PRODIS	Enable Discard Of Frames With Wrong Protocol Checksum 0 Frames with wrong checksum are not discarded. 1 If a TCP/IP, UDP/IP, or ICMP/IP frame is received that has a wrong TCP, UDP, or ICMP checksum, the frame is discarded. Discarding is only available when the RX FIFO operates in store and forward mode (RSFL cleared).
30 IPDIS	Enable Discard Of Frames With Wrong IPv4 Header Checksum

Table continues on the next page...

## ENETx\_RACC field descriptions (continued)

Field	Description
	0 Frames with wrong IPv4 header checksum are not discarded. 1 If an IPv4 frame is received with a mismatching header checksum, the frame is discarded. IPv6 has no header checksum and is not affected by this setting. Discarding is only available when the RX FIFO operates in store and forward mode (RSFL cleared).
31 PADREM	Enable Padding Removal For Short IP Frames 0 Padding not removed. 1 Any bytes following the IP payload section of the frame are removed from the frame.

### 11.1.5.41 Receive Classification Match Register for Class n (ENETx\_RCMRn)

This match register allows specifying up to four priorities, which are tested (OR'ed) simultaneously. The match detection uses the extracted VLAN field according to the rules for VLAN detection configured through the ECR register. If both match registers, RCMR1 and RCMR2, report a match at the same time, only the class 1 match is indicated as the final result.

Address: Base address + 1C8h offset + (4d × i), where i=0d to 1d

### ENETx\_RCMRn field descriptions

Field	Description
0–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 MATCHEN	Match Enable  <b>NOTE:</b> A comparison is done only on incoming VLAN frames. If no VLAN frame is received no match will occur.

Table continues on the next page...

**ENETx\_RCMRn field descriptions (continued)**

Field	Description
	<p>If both match registers have overlapping compare values and hence can match both on the same frame, only class 1 will be indicated and the class 2 match is ignored.</p> <p>0 Disabled (default): no compares will occur and the classification indicator for this class will never assert.</p> <p>1 The register contents are valid and a comparison with all compare values is done when a VLAN frame is received.</p>
16 Reserved	<p>This field is reserved. This read-only field is reserved and always has the value 0.</p>
17–19 CMP3	<p>Compare 3 Fourth value to compare against. If unused it must be set to the same value as CMP0.</p>
20 Reserved	<p>This field is reserved. This read-only field is reserved and always has the value 0.</p>
21–23 CMP2	<p>Compare 2 Third value to compare against. If unused it must be set to the same value as CMP0.</p>
24 Reserved	<p>This field is reserved. This read-only field is reserved and always has the value 0.</p>
25–27 CMP1	<p>Compare 1 Second value to compare against. If unused it must be set to the same value as CMP0.</p>
28 Reserved	<p>This field is reserved. This read-only field is reserved and always has the value 0.</p>
29–31 CMP0	<p>Compare 0 A three-bit value that will be compared with the frame's VLAN priority field (if a VLAN frame is received). All four compare values, CMP0..3, will be used in parallel. If any of the values match, a match for the class is reported (if MATCHEN is 1).</p> <p><b>NOTE:</b> To implement a single priority match, all four compare values must be set to the same value.</p>

**11.1.5.42 DMA Class Based Configuration (ENETx\_DMAnCFG)**

The DMA class based configuration registers are used to configure the DMA controller interface to support the additional class 1 (buffer descriptor ring 1) and class 2 (buffer descriptor ring 2) traffic and define configuration options such as bandwidth allocation as needed.

**NOTE**

The registers are cleared when ECR[ETHEREN] becomes 0.

Address: Base address + 1D8h offset + (4d × i), where i=0d to 1d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0								Reserved						CALC_NOIPG	DMA_CLASS_EN
W	[Shaded]								Reserved						CALC_NOIPG	DMA_CLASS_EN
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	IDLE_SLOPE															
W	IDLE_SLOPE															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**ENETx\_DMAnCFG field descriptions**

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–13 Reserved	This field is reserved. <b>NOTE:</b> Write only zeroes to this field.
14 CALC_NOIPG	Calculate no IPG Disable inclusion of IPG bytes for bandwidth calculations.  0 The traffic shaper function should consider 12 octets of IPG in addition to the frame data transferred for a frame when doing bandwidth calculations. This is the default. 1 Addition of 12 bytes for the IPG should be omitted when calculating the bandwidth (for traffic shaping, when writing a frame into the transmit FIFO, the shaper will usually consider 12 bytes of IPG for every frame as part of the bandwidth allocated by the frame. This addition can be suppressed, meaning short frames will become more bandwidth than large frames due to the relation of data to IPG overhead).
15 DMA_CLASS_EN	DMA class enable  0 The DMA controller's channel for the class is not used. <b>NOTE:</b> Disabling the DMA controller of a class also requires disabling the class match comparator for the class (see registers RCMRn). When class 1 and class 2 queues are disabled then their frames will be placed in queue 0. 1 Enable the DMA controller to support the corresponding descriptor ring for this class of traffic.
16–31 IDLE_SLOPE	Idle slope  16-bit value to define the per class idle slope setting used by the credit based shaper defining allocated bandwidth for the class. This value is used to calculate the BW (bandwidth) fraction, given by the equation, BW fraction = 1/(1+512/IDLE_SLOPE).  Idle slope is restricted to certain values. For values less than 128, idle slope = 2 <sup>n</sup> , where n = 0, 1, 2, ...6. For values equal to or greater than 128, idle slope = 128×m, where m = 1, 2, 3, ...12.

*Table continues on the next page...*

**ENETx\_DMAnCFG field descriptions (continued)**

Field	Description
	Example 1. BW fraction = 0.20 = 1/(1+(512/128)); therefore idleslope = 128. Example 2. BW fraction = 0.33 = 1/(1+(512/256)); therefore idleslope = 256. Example 3. BW fraction = 0.75 = 1/(1+(512/1536)); therefore idleslope = 1536. <b>NOTE:</b> For AVB applications, the BW fraction of class 1 and class 2 combined must not exceed .75.

**11.1.5.43 Receive Descriptor Active Register - Ring 1 (ENETx\_RDAR1)**

RDAR1 is a command register, written by the user, to indicate that the receive descriptor ring 1 has been updated, that is, that the driver produced empty receive buffers with the empty bit set.

Address: Base address + 1E0h offset

**ENETx\_RDAR1 field descriptions**

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 RDAR	Receive Descriptor Active  Always set to 1 when this register is written, regardless of the value written. This field is cleared by the MAC device when no additional empty descriptors remain in the receive ring. It is also cleared when ECR[ETHEREN] transitions from set to cleared or when ECR[RESET] is set.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

### 11.1.5.44 Transmit Descriptor Active Register - Ring 1 (ENETx\_TDAR1)

TDAR1 is a command register that the user writes to indicate that transmit descriptor ring 1 has been updated, that is, that transmit buffers have been produced by the driver with the ready bit set in the buffer descriptor.

The TDAR register is cleared at reset, when ECR[ETHEREN] transitions from set to cleared, or when ECR[RESET] is set.

Address: Base address + 1E4h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	
R	0							TDAR	0								
W	[Reserved]								[Reserved]

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31	
R	0																
W	[Reserved]																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

#### ENETx\_TDAR1 field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 TDAR	Transmit Descriptor Active  Always set to 1 when this register is written, regardless of the value written. This bit is cleared by the MAC device when no additional ready descriptors remain in the transmit ring. Also cleared when ECR[ETHEREN] transitions from set to cleared or when ECR[RESET] is set.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

### 11.1.5.45 Receive Descriptor Active Register - Ring 2 (ENETx\_RDAR2)

RDAR2 is a command register, written by the user, to indicate that the receive descriptor ring 2 has been updated, that is, that the driver produced empty receive buffers with the empty bit set.

Address: Base address + 1E8h offset

#### ENETx\_RDAR2 field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 RDAR	Receive Descriptor Active  Always set to 1 when this register is written, regardless of the value written. This field is cleared by the MAC device when no additional empty descriptors remain in the receive ring. It is also cleared when ECR[ETHEREN] transitions from set to cleared or when ECR[RESET] is set.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

### 11.1.5.46 Transmit Descriptor Active Register - Ring 2 (ENETx\_TDAR2)

TDAR2 is a command register that the user writes to indicate that transmit descriptor ring 2 has been updated, that is, that transmit buffers have been produced by the driver with the ready bit set in the buffer descriptor.

Address: Base address + 1ECh offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	
R	0							TDAR	0								
W	[Reserved]								[Reserved]

#### ENETx\_TDAR2 field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 TDAR	Transmit Descriptor Active  Always set to 1 when this register is written, regardless of the value written. This bit is cleared by the MAC device when no additional ready descriptors remain in the transmit ring. Also cleared when ECR[ETHEREN] transitions from set to cleared or when ECR[RESET] is set.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

### 11.1.5.47 QOS Scheme (ENETx\_QOS)

This register sets the QOS scheme.

#### NOTE

When both class 1 and class 2 are disabled, RX flushing for these rings must also be disabled.

## Ethernet MAC (ENET)

Address: Base address + 1F0h offset

### ENETx\_QOS field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 RX_FLUSH2	RX Flush Ring 2 Enable or disable RX Flush for ring 2. See <a href="#">Receive flushing</a> .  0 Disable 1 Enable
27 RX_FLUSH1	RX Flush Ring 1 Enable or disable RX Flush for ring 1. See <a href="#">Receive flushing</a> .  0 Disable 1 Enable
28 RX_FLUSH0	RX Flush Ring 0 Enable or disable RX Flush for ring 0. See <a href="#">Receive flushing</a> .  0 Disable 1 Enable
29–31 TX_SCHEME	TX scheme configuration Configuration information for DMA to select transmitter queue selection/arbitration scheme.  000 Credit-based scheme 001 Round-robin scheme 010-111 Reserved

### 11.1.5.48 Reserved Statistic Register (ENETx\_RMON\_T\_DROP)

Address: Base address + 200h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

W	[Shaded]																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**ENETx\_IEEE\_T\_DROP field descriptions**

Field	Description
0–31 Reserved	This read-only field always has the value 0.  This field is reserved.

**11.1.5.67 Frames Transmitted OK Statistic Register (ENETx\_IEEE\_T\_FRAME\_OK)**

Address: Base address + 24Ch offset

**ENETx\_IEEE\_T\_FRAME\_OK field descriptions**

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of frames transmitted OK  <b>NOTE:</b> Does not increment for the broadcast frames when broadcast reject is enabled and promiscuous mode is disabled within the receive control register (RCR).

**11.1.5.68 Frames Transmitted with Single Collision Statistic Register (ENETx\_IEEE\_T\_1COL)**

Address: Base address + 250h offset

**ENETx\_IEEE\_T\_1COL field descriptions**

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of frames transmitted with one collision

### 11.1.5.69 Frames Transmitted with Multiple Collisions Statistic Register (ENETx\_IEEE\_T\_MCOL)

Address: Base address + 254h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31	
R	0															COUNT																	
W	[Shaded]																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ENETx\_IEEE\_T\_MCOL field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of frames transmitted with multiple collisions

### 11.1.5.70 Frames Transmitted after Deferral Delay Statistic Register (ENETx\_IEEE\_T\_DEF)

Address: Base address + 258h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31	
R	0															COUNT																	
W	[Shaded]																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ENETx\_IEEE\_T\_DEF field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of frames transmitted with deferral delay

### 11.1.5.71 Frames Transmitted with Late Collision Statistic Register (ENETx\_IEEE\_T\_LCOL)

Address: Base address + 25Ch offset

#### ENETx\_IEEE\_T\_LCOL field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of frames transmitted with late collision

### 11.1.5.72 Frames Transmitted with Excessive Collisions Statistic Register (ENETx\_IEEE\_T\_EXCOL)

Address: Base address + 260h offset

#### ENETx\_IEEE\_T\_EXCOL field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of frames transmitted with excessive collisions

### 11.1.5.73 Frames Transmitted with Tx FIFO Underrun Statistic Register (ENETx\_IEEE\_T\_MACERR)

Address: Base address + 264h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31	
R	0															COUNT																	
W	[Shaded]																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ENETx\_IEEE\_T\_MACERR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of frames transmitted with transmit FIFO underrun

### 11.1.5.74 Frames Transmitted with Carrier Sense Error Statistic Register (ENETx\_IEEE\_T\_CSERR)

Address: Base address + 268h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31	
R	0															COUNT																	
W	[Shaded]																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ENETx\_IEEE\_T\_CSERR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of frames transmitted with carrier sense error

### 11.1.5.75 Reserved Statistic Register (ENETx\_IEEE\_T\_SQE)

Address: Base address + 26Ch offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31	
R	0															COUNT																	
W	[Shaded]																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**ENETx\_IEEE\_T\_SQE field descriptions**

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	This read-only field is reserved and always has the value 0. <b>NOTE:</b> Counter not implemented as no SQE information is available.

**11.1.5.76 Flow Control Pause Frames Transmitted Statistic Register (ENETx\_IEEE\_T\_FDXFC)**

Address: Base address + 270h offset

**ENETx\_IEEE\_T\_FDXFC field descriptions**

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of flow-control pause frames transmitted

**11.1.5.77 Octet Count for Frames Transmitted w/o Error Statistic Register (ENETx\_IEEE\_T\_OCTETS\_OK)**

Address: Base address + 274h offset

**ENETx\_IEEE\_T\_OCTETS\_OK field descriptions**

Field	Description
0–31 COUNT	Octet count for frames transmitted without error  <b>NOTE</b> Counts total octets (includes header and FCS fields).

### 11.1.5.78 Rx Packet Count Statistic Register (ENETx\_RMON\_R\_PACKETS)

Address: Base address + 284h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31	
R	0															COUNT																	
W	[Shaded]																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ENETx\_RMON\_R\_PACKETS field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of packets received

### 11.1.5.79 Rx Broadcast Packets Statistic Register (ENETx\_RMON\_R\_BC\_PKT)

Address: Base address + 288h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31	
R	0															COUNT																	
W	[Shaded]																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ENETx\_RMON\_R\_BC\_PKT field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of receive broadcast packets

### 11.1.5.80 Rx Multicast Packets Statistic Register (ENETx\_RMON\_R\_MC\_PKT)

Address: Base address + 28Ch offset

#### ENETx\_RMON\_R\_MC\_PKT field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of receive multicast packets

### 11.1.5.81 Rx Packets with CRC/Align Error Statistic Register (ENETx\_RMON\_R\_CRC\_ALIGN)

Address: Base address + 290h offset

#### ENETx\_RMON\_R\_CRC\_ALIGN field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of receive packets with CRC or align error

### 11.1.5.82 Rx Packets with Less Than 64 Bytes and Good CRC Statistic Register (ENETx\_RMON\_R\_UNDERSIZE)

Address: Base address + 294h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

#### ENETx\_RMON\_R\_OVERSIZE field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of receive packets greater than MAX_FL and good CRC

### 11.1.5.84 Rx Packets Less Than 64 Bytes and Bad CRC Statistic Register (ENETx\_RMON\_R\_FRAG)

Address: Base address + 29Ch offset

**ENETx\_RMON\_R\_FRAG field descriptions**

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of receive packets with less than 64 bytes and bad CRC

### 11.1.5.85 Rx Packets Greater Than MAX\_FL Bytes and Bad CRC Statistic Register (ENETx\_RMON\_R\_JAB)

Address: Base address + 2A0h offset

**ENETx\_RMON\_R\_JAB field descriptions**

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of receive packets greater than MAX_FL and bad CRC

### 11.1.5.86 Reserved Statistic Register (ENETx\_RMON\_R\_RESVD\_0)

Address: Base address + 2A4h offset

### ENETx\_RMON\_R\_RESVD\_0 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

### 11.1.5.87 Rx 64-Byte Packets Statistic Register (ENETx\_RMON\_R\_P64)

Address: Base address + 2A8h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

#### ENETx\_IEEE\_R\_MACERR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Receive FIFO overflow count

### 11.1.5.100 Flow Control Pause Frames Received Statistic Register (ENETx\_IEEE\_R\_FDXFC)

Address: Base address + 2DCh offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0															COUNT																
W	[Shaded]																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ENETx\_IEEE\_R\_FDXFC field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of flow-control pause frames received

### 11.1.5.101 Octet Count for Frames Received without Error Statistic Register (ENETx\_IEEE\_R\_OCTETS\_OK)

Address: Base address + 2E0h offset

#### ENETx\_IEEE\_R\_OCTETS\_OK field descriptions

Field	Description
0–31 COUNT	Number of octets for frames received without error  <b>NOTE:</b> Counts total octets (includes header and FCS fields). Does not increment for the broadcast frames when broadcast reject is enabled and promiscuous mode is disabled within the receive control register (RCR).

### 11.1.5.102 Adjustable Timer Control Register (ENETx\_ATCR)

ATCR command fields can trigger the corresponding events directly. It is not necessary to preserve any of the configuration fields when a command field is set in the register, that is, no read-modify-write is required.

Address: Base address + 400h offset

## ENETx\_ATCR field descriptions

Field	Description
0–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 SLAVE	Enable Timer Slave Mode  0 The timer is active and all configuration fields in this register are relevant. 1 The internal timer is disabled and the externally provided timer value is used. All other fields, except CAPTURE, in this register have no effect. CAPTURE can still be used to capture the current timer value.
19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 CAPTURE	Capture Timer Value  When this field is set, all other fields are ignored during a write. This field automatically clears to 0 after the command completes.  <b>NOTE:</b> To ensure that the correct time value is read from the ATVR register, a minimum amount of time must elapse from issuing this command to reading the ATVR register. This minimum time is defined by the greater of either six register clock cycles or six 1588/timestamp clock cycles.  0 No effect. 1 The current time is captured and can be read from the ATVR register.
21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 RESTART	Reset Timer  Resets the timer to zero. This has no effect on the counter enable. If the counter is enabled when this field is set, the timer is reset to zero and starts counting from there. When set, all other fields are ignored during a write. This field automatically clears to 0 after the command completes.  <b>NOTE:</b> The Reset Timer command requires at least 6 clock cycles of either the register clock or the 1588/timestamp clock, whichever is greater, to complete.
23 Reserved	This field is reserved.
24 PINPER	Enables event signal output assertion on period event.  <b>NOTE:</b> Not all devices contain the event signal output. See the chip configuration details.  0 Disable. 1 Enable.
25 Reserved	This field is reserved.
26 Reserved	This field is reserved.  <b>NOTE:</b> This field must be written always with one.
27 PEREN	Enable Periodical Event  0 Disable. 1 A period event interrupt can be generated (EIR[TS_TIMER]) and the event signal output is asserted when the timer wraps around according to the periodic setting ATPER. The timer period value must be set before setting this bit.  <b>NOTE:</b> Not all devices contain the event signal output. See the chip configuration details.

*Table continues on the next page...*

### ENETx\_ATCR field descriptions (continued)

Field	Description
28 OFFRST	Reset Timer On Offset Event 0 The timer is not affected and no action occurs, besides clearing OFFEN, when the offset is reached. 1 If OFFEN is set, the timer resets to zero when the offset setting is reached. The offset event does not cause a timer interrupt.
29 OFFEN	Enable One-Shot Offset Event 0 Disable. 1 The timer can be reset to zero when the given offset time is reached (offset event). The field is cleared when the offset event is reached, so no further event occurs until the field is set again. The timer offset value must be set before setting this field.
30 Reserved	This field is reserved.
31 EN	Enable Timer 0 The timer stops at the current value. 1 The timer starts incrementing.

### 11.1.5.103 Timer Value Register (ENETx\_ATVR)

Address: Base address + 404h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	ATIME																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ENETx\_ATVR field descriptions

Field	Description
0–31 ATIME	A write sets the timer. A read returns the last captured value. To read the current value, issue a capture command (i.e., set ATCR[CAPTURE]) prior to reading this register.

### 11.1.5.104 Timer Offset Register (ENETx\_ATOFF)

Address: Base address + 408h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	OFFSET																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ENETx\_ATOFF field descriptions

Field	Description
0–31 OFFSET	Offset value for one-shot event generation. When the timer reaches the value, an event can be generated to reset the counter. If the increment value in ATINC is given in true nanoseconds, this value is also given in true nanoseconds.

### 11.1.5.105 Timer Period Register (ENETx\_ATPER)

Address: Base address + 40Ch offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R																																
W																																
Reset	0	0	1	1	1	0	1	1	1	0	0	1	1	0	1	0	1	1	0	0	1	0	1	0	0	0	0	0	0	0	0	0

#### ENETx\_ATPER field descriptions

Field	Description
0–31 PERIOD	<p>Value for generating periodic events. Each instance the timer reaches this value, the period event occurs and the timer restarts. If the increment value in ATINC is given in true nanoseconds, this value is also given in true nanoseconds. The value should be initialized to 1,000,000,000 (1×10<sup>9</sup>) to represent a timer wrap around of one second. The increment value set in ATINC should be set to the true nanoseconds of the period of clock ts_clk, hence implementing a true 1 second counter.</p> <p><b>NOTE:</b> The value of PERIOD has the following constraint:  <math>2^{32} - \text{ENET\_ATINC}[\text{INC\_COR}] - 3 \times \text{ENET\_ATINC}[\text{INC}] \geq \text{PERIOD} &gt; 0.</math></p>

### 11.1.5.106 Timer Correction Register (ENETx\_ATCOR)

Address: Base address + 410h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W	[Shaded]	[Shaded]							[Shaded]	[Shaded]								
Reset	0	0	0	0	0	0	0	0		0	0	0	0	0	0	0	0	0

#### ENETx\_ATINC field descriptions

Field	Description
0–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–23 INC_CORR	Correction Increment Value  This value is added every time the correction timer expires (every clock cycle given in ATCOR). A value less than INC slows down the timer. A value greater than INC speeds up the timer.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–31 INC	Clock Period Of The Timestamping Clock (ts_clk) In Nanoseconds  The timer increments by this amount each clock cycle. For example, set to 10 for 100 MHz, 8 for 125 MHz, 5 for 200 MHz.  <b>NOTE:</b> For highest precision, use a value that is an integer fraction of the period set in ATPER.

### 11.1.5.108 Timestamp of Last Transmitted Frame (ENETx\_ATSTMP)

Address: Base address + 418h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15		16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31	
R	TIMESTAMP																																	
W	[Shaded]																																	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0		0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ENETx\_ATSTMP field descriptions

Field	Description
0–31 TIMESTAMP	Timestamp of the last frame transmitted by the core that had TxBD[TS] set . This register is only valid when EIR[TS_AVAIL] is set.

### 11.1.5.109 Timer Global Status Register (ENETx\_TGSR)

Address: Base address + 604h offset

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### ENETx\_TCSRn field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 TF	Timer Flag  Sets when input capture or output compare occurs. This flag is double buffered between the module clock and 1588 clock domains. When this field is 1, it can be cleared to 0 by writing 1 to it.  0 Input Capture or Output Compare has not occurred. 1 Input Capture or Output Compare has occurred.
25 TIE	Timer Interrupt Enable  0 Interrupt is disabled 1 Interrupt is enabled
26–29 TMODE	Timer Mode  Updating the Timer Mode field takes a few cycles to register because it is synchronized to the 1588 clock. The version of Timer Mode returned on a read is from the 1588 clock domain. When changing Timer Mode, always disable the channel and read this register to verify the channel is disabled first.  0000 Timer Channel is disabled. 0001 Timer Channel is configured for Input Capture on rising edge. 0010 Timer Channel is configured for Input Capture on falling edge. 0011 Timer Channel is configured for Input Capture on both edges. 0100 Timer Channel is configured for Output Compare - software only. 0101 Timer Channel is configured for Output Compare - toggle output on compare. 0110 Timer Channel is configured for Output Compare - clear output on compare. 0111 Timer Channel is configured for Output Compare - set output on compare. 1000 Reserved 1010 Timer Channel is configured for Output Compare - clear output on compare, set output on overflow. 10X1 Timer Channel is configured for Output Compare - set output on compare, clear output on overflow. 110X Reserved

Table continues on the next page...

**ENETx\_TCSRn field descriptions (continued)**

Field	Description
	1110 Timer Channel is configured for Output Compare - pulse output low on compare for one 1588-clock cycle. 1111 Timer Channel is configured for Output Compare - pulse output high on compare for one 1588-clock cycle.
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 TDRE	Timer DMA Request Enable 0 DMA request is disabled 1 DMA request is enabled

**11.1.5.111 Timer Compare Capture Register (ENETx\_TCCRn)**

Address: Base address + 60Ch offset + (8d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31					
R	TCC																																				
W	TCC																																				
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0				

**ENETx\_TCCRn field descriptions**

Field	Description
0–31 TCC	<p>Timer Capture Compare</p> <p>This register is double buffered between the module clock and 1588 clock domains.</p> <p>When configured for compare, the 1588 clock domain updates with the value in the module clock domain whenever the Timer Channel is first enabled and on each subsequent compare. Write to this register with the first compare value before enabling the Timer Channel. When the Timer Channel is enabled, write the second compare value either immediately, or at least before the first compare occurs. After each compare, write the next compare value before the previous compare occurs and before clearing the Timer Flag.</p> <p>The compare occurs one 1588 clock cycle after the IEEE 1588 Counter increments past the compare value in the 1588 clock domain. If the compare value is less than the value of the 1588 Counter when the Timer Channel is first enabled, then the compare does not occur until following the next overflow of the 1588 Counter. If the compare value is greater than the IEEE 1588 Counter when the 1588 Counter overflows, or the compare value is less than the value of the IEEE 1588 Counter after the overflow, then the compare occurs one 1588 clock cycle following the overflow.</p> <p>When configured for capture, the value of the IEEE 1588 Counter is captured into the 1588 clock domain and then updated into the module clock domain, provided the Timer Flag is clear. Always read the capture value before clearing the Timer Flag.</p>

**11.1.6 Functional description**

This section provides a complete functional description of the MAC-NET core.

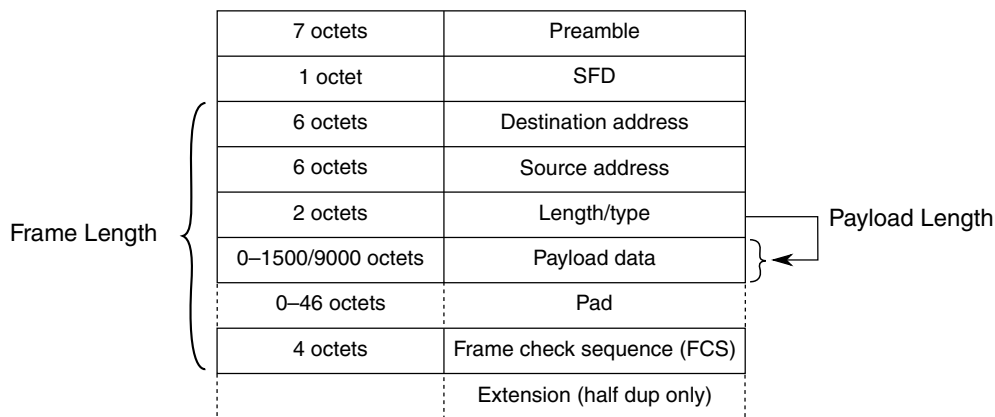

### 11.1.6.1 Ethernet MAC frame formats

The IEEE 802.3 standard defines the Ethernet frame format as follows:

- Minimum length of 64 bytes
- Maximum length of 1518 bytes excluding the preamble and the start frame delimiter (SFD) bytes

An Ethernet frame consists of the following fields:

- Seven bytes preamble
- Start frame delimiter (SFD)
- Two address fields
- Length or type field
- Data field
- Frame check sequence (CRC value)
- Extension field is defined only for Gigabit Ethernet half-duplex implementations and is not supported by the MAC core

**Figure 11-2. MAC frame format overview**

Optionally, MAC frames can be VLAN-tagged with an additional four-byte field inserted between the MAC source address and the type/length field. VLAN tagging is defined by the IEEE P802.1q specification. VLAN-tagged frames have a maximum length of 1522 bytes, excluding the preamble and the SFD bytes.

Figure 11-3. VLAN-tagged MAC frame format overview

Table 11-5. MAC frame definition

Term	Description
Frame length	Defines the length, in octets, of the complete frame without preamble and SFD. A frame has a valid length if it contains at least 64 octets and does not exceed the programmed maximum length.
Payload length	The length/type field indicates the length of the frame's payload section. The most significant byte is sent/received first. <ul style="list-style-type: none"> <li>If the length/type field is set to a value less than 46, the payload is padded so that the minimum frame length requirement (64 bytes) is met. For VLAN-tagged frames, a value less than 42 indicates a padded frame.</li> <li>If the length/type field is set to a value larger than the programmed frame maximum length (e.g. 1518) it is interpreted as a type field.</li> </ul>
Destination and source address	48-bit MAC addresses. The least significant byte is sent/received first and the first two least significant bits of the MAC address distinguish MAC frames, as detailed in <a href="#">MAC address check</a> .

### Note

Although the IEEE specification defines a maximum frame length, the MAC core provides the flexibility to program any value for the frame maximum length.

#### 11.1.6.1.1 Pause Frames

The receiving device generates a pause frame to indicate a congestion to the emitting device, which should stop sending data.

Pause frames are indicated by the length/type set to 0x8808. The two first bytes of a pause frame following the type, defines a 16-bit opcode field set to 0x0001 always. A 16-bit pause quanta is defined in the frame payload bytes 2 (P1) and 3 (P2) as defined in the following table. The P1 pause quanta byte is the most significant.

**Table 11-6. Pause Frame Format (Values in Hex)**

1	2	3	4	5	6	7	8	9	10	11	12	13	14
55	55	55	55	55	55	55	D5	01	80	C2	00	00	01
Preamble							SFD	Multicast Destination Address					
15	16	17	18	19	20	21	22	23	24	25	26	27–68	
00	00	00	00	00	00	88	08	00	01	hi	lo	00	
Source Address						Type		Opcode		P1	P2	pad (42)	
69	70	71	72										
26	6B	AE	0A										
CRC-32													

There is no payload length field found within a pause frame and a pause frame is always padded with 42 bytes (0x00).

If a pause frame with a pause value greater than zero (XOFF condition) is received, the MAC stops transmitting data as soon the current frame transfer is completed. The MAC stops transmitting data for the value defined in pause quanta. One pause quanta fraction refers to 512 bit times.

If a pause frame with a pause value of zero (XON condition) is received, the transmitter is allowed to send data immediately (see [Full-duplex flow control operation](#) for details).

### 11.1.6.1.2 Magic packets

A magic packet is a unicast, multicast, or broadcast packet, which carries a defined sequence in the payload section.

Magic packets are received and inspected only under specific conditions as described in [Magic packet detection](#).

The defined sequence to decode a magic packet is formed with a synchronization stream which consists of six consecutive 0xFF bytes, and is followed by sequence of sixteen consecutive unicast MAC addresses of the node to be awakened.

This sequence can be located anywhere in the magic packet payload. The magic packet is formed with a standard Ethernet header, optional padding, and CRC.

### 11.1.6.2 IP and higher layers frame format

The following sections use the term datagram to describe the protocol specific data unit that is found within the payload section of its container entity.

For example, an IP datagram specifies the payload section of an Ethernet frame. A TCP datagram specifies the payload section within an IP datagram.

### 11.1.6.2.1 Ethernet types

IP datagrams are carried in the payload section of an Ethernet frame. The Ethernet frame type/length field discriminates several datagram types.

The following table lists the types of interest:

**Table 11-7. Ethernet type value examples**

Type	Description
0x8100	VLAN-tagged frame. The actual type is found 4 octets later in the frame.
0x0800	IPv4
0x0806	ARP
0x86DD	IPv6

### 11.1.6.2.2 IPv4 datagram format

The following figure shows the IP Version 4 (IPv4) header, which is located at the beginning of an IP datagram. It is organized in 32-bit words. The first byte sent/received is the leftmost byte of the first word (in other words, version/IHL field).

The IP header can contain further options, which are always padded if necessary to guarantee the payload following the header is aligned to a 32-bit boundary.

The IP header is immediately followed by the payload, which can contain further protocol headers (for example, TCP or UDP, as indicated by the protocol field value). The complete IP datagram is transported in the payload section of an Ethernet frame.

**Table 11-8. IPv4 header format**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Version				IHL				TOS				Length																			
Fragment ID								Flags		Fragment offset																					
TTL				Protocol				Header checksum																							
Source address																															
Destination address																															
Options																															

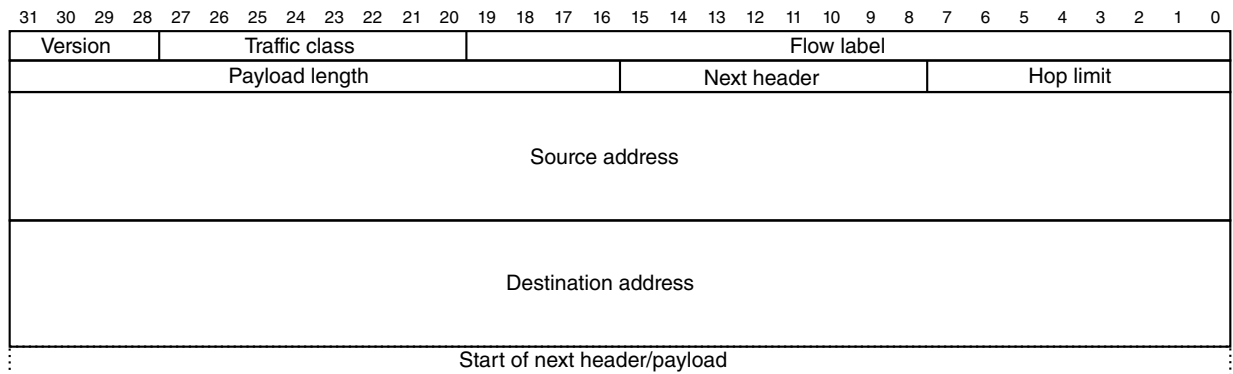

**Table 11-9. IPv4 header fields**

Field name	Description
Version	4-bit IP version information. 0x4 for IPv4 frames.
IHL	4-bit Internet header length information. Determines number of 32-bit words found within the IP header. If no options are present, the default value is 0x5.
TOS	Type of service/DiffServ field.
Length	Total length of the datagram in bytes, including all octets of header and payload.
Fragment ID, flags, fragment offset	Fields used for IP fragmentation.
TTL	Time-to-live. In effect, is decremented at each router arrival. If zero, datagram must be discarded.
Protocol	Identifier of protocol that follows in the datagram.
Header checksum	Checksum of IP header. For computational purposes, this field's value is zero.
Source address	Source IP address.
Destination address	Destination IP address.

**11.1.6.2.3 IPv6 datagram format**

The following figure shows the IP version 6 (IPv6) header, which is located at the beginning of an IP datagram. It is organized in 32-bit words and has a fixed length of ten words (40 bytes). The next header field identifies the type of the header that follows the IPv6 header. It is defined similar to the protocol identifier within IPv4, with new definitions for identifying extension headers. These headers can be inserted between the IPv6 header and the protocol header, which will shift the protocol header accordingly. The accelerator currently only supports IPv6 without extension headers (in other words, the next header specifies TCP, UDP, or IMCP).

The first byte sent/received is the leftmost byte of the first word (in other words, version/traffic class fields).

**Figure 11-4. IPv6 header format**

**Table 11-10. IPv6 header fields**

Field name	Description
Version	4-bit IP version information. 0x6 for all IPv6 frames.
Traffic class	8-bit field defining the traffic class.
Flow label	20-bit flow label identifying frames of the same flow.
Payload length	16-bit length of the datagram payload in bytes. It includes all octets following the IPv6 header.
Next header	Identifies the header that follows the IPv6 header. This can be the protocol header or any IPv6 defined extension header.
Hop limit	Hop counter, decremented by one by each station that forwards the frame. If hop limit is 0 the frame must be discarded.
Source address	128-bit IPv6 source address.
Destination address	128-bit IPv6 destination address.

#### 11.1.6.2.4 Internet Control Message Protocol (ICMP) datagram format

An internet control message protocol (ICMP) is found following the IP header, if the protocol identifier is 1. The ICMP datagram has a four-octet header followed by additional message data.

**Table 11-11. ICMP header format**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Type				Code				Checksum																							
ICMP message data																															

**Table 11-12. IP header fields**

Field name	Description
Type	8-bit type information
Code	8-bit code that is related to the message type
Checksum	16-bit one's complement checksum over the complete ICMP datagram

#### 11.1.6.2.5 User Datagram Protocol (UDP) datagram format

A user datagram protocol header is found after the IP header, when the protocol identifier is 17.

The payload of the datagram is after the UDP header. The header byte order follows the conventions given for the IP header above.

**Table 11-13. UDP header format**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Source port												Destination port																			
Length												Checksum																			

**Table 11-14. UDP header fields**

Field name	Description
Source port	Source application port
Destination port	Destination application port
Length	Length of user data which immediately follows the header, including the UDP header (that is, minimum value is 8)
Checksum	Checksum over the complete datagram and some IP header information

### 11.1.6.2.6 TCP datagram format

A TCP header is found following the IP header, when the protocol identifier has a value of 6.

The TCP payload immediately follows the TCP header.

**Table 11-15. TCP header format**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0				
Source port												Destination port																							
Sequence number																																			
Acknowledgement number																																			
Offset				Reserved				Flags				Window																							
Checksum																Urgent pointer																			
Options																																			

**Table 11-16. TCP header fields**

Field name	Description
Source port	Source application port
Destination port	Destination application port
Sequence number	Transmit sequence number
Ack. number	Receive sequence number
Offset	Data offset, which is number of 32-bit words within TCP header — if no options selected, defaults to value of 5
Flags	URG, ACK, PSH, RST, SYN, FIN flags

*Table continues on the next page...*

**Table 11-16. TCP header fields (continued)**

Field name	Description
Window	TCP receive window size information
Checksum	Checksum over the complete datagram (TCP header and data) and IP header information
Options	Additional 32-bit words for protocol options

### 11.1.6.3 IEEE 1588 message formats

The following sections describe the IEEE 1588 message formats.

#### 11.1.6.3.1 Transport encapsulation

The precision time protocol (PTP) datagrams are encapsulated in Ethernet frames using the UDP/IP transport mechanism, or optionally, with the newer 1588v2 directly in Ethernet frames (layer 2).

Typically, multicast addresses are used to allow efficient distribution of the synchronization messages.

##### 11.1.6.3.1.1 UDP/IP

The 1588 messages (v1 and v2) can be transported using UDP/IP multicast messages.

[Table 11-17](#) shows IP multicast groups defined for PTP. The table also shows their respective MAC layer multicast address mapping according to RFC 1112 (last three octets of IP follow the fixed value of 01-00-5E).

**Table 11-17. UDP/IP multicast domains**

Name	IP Address	MAC Address mapping
DefaultPTPdomain	224.0.1.129	01-00-5E-00-01-81
AlternatePTPdomain1	224.0.1.130	01-00-5E-00-01-82
AlternatePTPdomain2	224.0.1.131	01-00-5E-00-01-83
AlternatePTPdomain3	224.0.1.132	01-00-5E-00-01-84

**Table 11-18. UDP port numbers**

Message type	UDP port	Note
Event	319	Used for SYNC and DELAY_REQUEST messages
General	320	All other messages (for example, follow-up, delay-response)

### 11.1.6.3.1.2 Native Ethernet (PTPv2)

In addition to using UDP/IP frames, IEEE 1588v2 defines a native Ethernet frame format that uses ethertype = 0x88F7. The payload of the Ethernet frame immediately contains the PTP datagram, starting with the PTPv2 header.

Besides others, version 2 adds a peer delay mechanism to allow delay measurements between individual point-to-point links along a path over multiple nodes. The following multicast domains are also defined in PTPv2.

**Table 11-19. PTPv2 multicast domains**

Name	MAC address
Normal messages	01-1B-19-00-00-00
Peer delay messages	01-80-C2-00-00-0E

### 11.1.6.3.2 PTP header

All PTP frames contain a common header that determines the protocol version and the type of message, which defines the remaining content of the message.

All multi-octet fields are transmitted in big-endian order (the most significant byte is transmitted/received first).

The last four bits of versionPTP are at the same position (second byte) for PTPv1 and PTPv2 headers. This allows accurate identification by inspecting the first two bytes of the message.

#### 11.1.6.3.2.1 PTPv1 header

**Table 11-20. Common PTPv1 message header**

Offset	Octets	Bits							
		7	6	5	4	3	2	1	0
0	2	versionPTP = 0x0001							
2	2	versionNetwork							
4	16	subdomain							
20	1	messageType							
21	1	sourceCommunicationTechnology							
22	6	sourceUuid							
28	2	sourcePortId							
30	2	sequenceId							

*Table continues on the next page...*

**Table 11-20. Common PTPv1 message header (continued)**

Offset	Octets	Bits							
		7	6	5	4	3	2	1	0
32	1	control							
33	1	0x00							
34	2	flags							
36	4	reserved							

The type of message is encoded in the messageType and control fields as shown in [Table 11-21](#) :

**Table 11-21. PTPv1 message type identification**

messageType	control	Message Name	Message
0x01	0x0	SYNC	Event message
0x01	0x1	DELAY_REQ	Event message
0x02	0x2	FOLLOW_UP	General message
0x02	0x3	DELAY_RESP	General message
0x02	0x4	MANAGEMENT	General message
other	other	—	Reserved

The field sequenceId is used to non-ambiguously identify a message.

### 11.1.6.3.2.2 PTPv2 header

**Table 11-22. Common PTPv2 message header**

Offset	Octets	Bits							
		7	6	5	4	3	2	1	0
0	1	transportSpecific				messageId			
1	1	reserved				versionPTP = 0x2			
2	2	messageLength							
4	1	domainNumber							
5	1	reserved							
6	2	flags							
8	8	correctionField							
16	4	reserved							
20	10	sourcePortIdentity							
30	2	sequenceId							
32	1	control							
33	1	logMeanMessageInterval							

The type of message is encoded in the field `messageId` as follows:

**Table 11-23. PTPv2 message type identification**

messageId	Message name	Message
0x0	SYNC	Event message
0x1	DELAY_REQ	Event message
0x2	PATH_DELAY_REQ	Event message
0x3	PATH_DELAY_RESP	Event message
0x4–0x7	—	Reserved
0x8	FOLLOW_UP	General message
0x9	DELAY_RESP	General message
0xa	PATH_DELAY_FOLLOW_UP	General message
0xb	ANNOUNCE	General message
0xc	SIGNALING	General message
0xd	MANAGEMENT	General message

The PTPv2 flags field contains further details on the type of message, especially if one-step or two-step implementations are used. The one- or two-step implementation is controlled by the `TWO_STEP` bit in the first octet of the flags field as shown below. Reserved bits are cleared.

**Table 11-24. PTPv2 message flags field definitions**

Bit	Name	Description
0	ALTERNATE_MASTER	See IEEE 1588 Clause 17.4
1	TWO_STEP	1 Two-step clock 0 One-step clock
2	UNICAST	1 Transport layer address uses a unicast destination address 0 Multicast is used
3	—	Reserved
4	—	Reserved
5	Profile specific	
6	Profile specific	
7	—	Reserved

#### 11.1.6.4 MAC receive

The MAC receive engine performs the following tasks:

- Check frame framing

- Remove frame preamble and frame SFD field
- Discard frame based on frame destination address field
- Terminate pause frames
- Check frame length
- Remove payload padding if it exists
- Calculate and verify CRC-32
- Write received frames in the core receive FIFO

If the MAC is programmed to operate in half-duplex mode, it will also check if the frame is received with a collision.

**Figure 11-5. MAC receive flow**

#### 11.1.6.4.1 Collision detection in half-duplex mode

If the packet is received with a collision detected during reception of the first 64 bytes, the packet is discarded (if frame size was less than ~14 octets) or transmitted to the user application with an error and RxBD[CE] set.

### 11.1.6.4.2 Preamble processing

The IEEE 802.3 standard allows a maximum size of 56 bits (seven bytes) for the preamble, while the MAC core allows any preamble length, including zero length preamble.

The MAC core checks for the start frame delimiter (SFD) byte. If the next byte of the preamble, which is different from 0x55, is not 0xD5, the frame is discarded.

Although the IEEE specification dictates that the inner-packet gap should be at least 96 bits, the MAC core is designed to accept frames separated by only 64 10/100-Mbit/s operation (MII) bits.

The MAC core removes the preamble and SFD bytes.

### 11.1.6.4.3 MAC address check

The destination address bit 0 differentiates between multicast and unicast addresses.

- If bit 0 is 0, the MAC address is an individual (unicast) address.
- If bit 0 is 1, the MAC address defines a group (multicast) address.
- If all 48 bits of the MAC address are set, it indicates a broadcast address.

#### 11.1.6.4.3.1 Unicast address check

If a unicast address is received, the destination MAC address is compared to the node MAC address programmed by the host in the PADDR1/2 registers.

If the destination address matches any of the programmed MAC addresses, the frame is accepted.

If Promiscuous mode is enabled ( $\text{RCR}[\text{PROM}] = 1$ ) no address checking is performed and all unicast frames are accepted.

#### 11.1.6.4.3.2 Multicast and unicast address resolution

The hash table algorithm used in the group and individual hash filtering operates as follows.

- The 48-bit destination address is mapped into one of 64 bits, represented by 64 bits in  $\text{ENET}_n\text{\_GAUR/GALR}$  (group address hash match) or  $\text{ENET}_n\text{\_IAUR/IALR}$  (individual address hash match).

- This mapping is performed by passing the 48-bit address through the on-chip 32-bit CRC generator and selecting the six most significant bits of the CRC-encoded result to generate a number between 0 and 63.
- The msb of the CRC result selects ENET $n$ \_GAUR (msb = 1) or ENET $n$ \_GALR (msb = 0).
- The five lsbs of the hash result select the bit within the selected register.
- If the CRC generator selects a bit set in the hash table, the frame is accepted; else, it is rejected.

For example, if eight group addresses are stored in the hash table and random group addresses are received, the hash table prevents roughly 56/64 (or 87.5%) of the group address frames from reaching memory. Those that do reach memory must be further filtered by the processor to determine if they truly contain one of the eight desired addresses.

The effectiveness of the hash table declines as the number of addresses increases.

The user must initialize the hash table registers. Use this CRC32 polynomial to compute the hash:

- $FCS(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x^1 + 1$

If Promiscuous mode is enabled (ENET $n$ \_RCR[PROM] = 1) all unicast and multicast frames are accepted regardless of ENET $n$ \_GAUR/GALR and ENET $n$ \_IAUR/IALR settings.

#### 11.1.6.4.3.3 Broadcast address reject

All broadcast frames are accepted if BC\_REJ is cleared or ENET $n$ \_RCR[PROM] is set. If PROM is cleared when ENET $n$ \_RCR[BC\_REJ] is set, all broadcast frames are rejected.

**Table 11-25. Broadcast address reject programming**

PROM	BC_REJ	Broadcast frames
0	0	Accepted
0	1	Rejected
1	0	Accepted
1	1	Accepted

#### 11.1.6.4.3.4 Miss-bit implementation

For higher layer filtering purposes, RxBD[M] indicates an address miss when the MAC operates in promiscuous mode and accepts a frame that would otherwise be rejected.

If a group/individual hash or exact match does not occur and Promiscuous mode is enabled (RCR[PROM] = 1), the frame is accepted and the M bit is set in the buffer descriptor; otherwise, the frame is rejected.

This means the status bit is set in any of the following conditions during Promiscuous mode:

- A broadcast frame is received when BC\_REJ is set
- A unicast is received that does not match either:
  - Node address (PALR[PADDR1] and PAUR[PADDR2])
  - Hash table for unicast (IAUR[IADDR1] and IALR[IADDR2])
- A multicast is received that does not match the GAUR[GADDR1] and GALR[GADDR2] hash table entries

#### 11.1.6.4.4 Frame length/type verification: payload length check

If the length/type is less than 0x600 and NLC is set, the MAC checks the payload length and reports any error in the frame status word and interrupt bit PLR.

If the length/type is greater than or equal to 0x600, the MAC interprets the field as a type and no payload length check is performed.

The length check is performed on VLAN and stacked VLAN frames. If a padded frame is received, no length check can be performed due to the extended frame payload because padded frames can never have a payload length error.

#### 11.1.6.4.5 Frame length/type verification: frame length check

When the receive frame length exceeds MAX\_FL bytes, the BABR interrupt is generated and the RxBD[LG] bit is set.

The frame is not truncated unless the frame length exceeds the value programmed in ENET<sub>n</sub>\_FTRL[TRUNC\_FL]. If the frame is truncated, RxBD[TR] is set. In addition, a truncated frame always has the CRC error indication set (RxBD[CR]).

#### 11.1.6.4.6 VLAN frames processing

VLAN frames have a length/type field set to 0x8100 immediately followed by a 16-Bit VLAN control information field.

VLAN-tagged frames are received as normal frames because the VLAN tag is not interpreted by the MAC function, and are pushed complete with the VLAN tag to the user application. If the length/type field of the VLAN-tagged frame, which is found four octets later in the frame, is less than 42, the padding is removed. In addition, the frame status word (RxBD[NO]) indicates that the current frame is VLAN tagged.

#### 11.1.6.4.7 Pause frame termination

The receive engine terminates pause frames and does not transfer them to the receive FIFO. The quanta is extracted and sent to the MAC transmit path via a small internal clock rate decoupling asynchronous FIFO.

The quanta is written only if a correct CRC and frame length are detected by the control state machine. If not, the quanta is discarded and the MAC transmit path is not paused.

Good pause frames are ignored if ENET $n$ \_RCR[FCE] is cleared and are forwarded to the client interface when ENET $n$ \_RCR[PAUFWD] is set.

#### 11.1.6.4.8 CRC check

The CRC-32 field is checked and forwarded to the core FIFO interface if ENET $n$ \_RCR[CRCFWD] is cleared and ENET $n$ \_RCR[PADEN] is set.

When CRCFWD is set (regardless of PADEN), the CRC-32 field is checked and terminated (not transmitted to the FIFO).

The CRC polynomial, as specified in the 802.3 standard, is:

- $$FCS(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x^1 + 1$$

The 32 bits of the CRC value are placed in the frame check sequence (FCS) field with the  $x^{31}$  term as right-most bit of the first octet. The CRC bits are thus received in the following order:  $x^{31}$ ,  $x^{30}$ , ...,  $x^1$ ,  $x^0$ .

If a CRC error is detected, the frame is marked invalid and RxBD[CR] is set.

### 11.1.6.4.9 Frame padding removal

When a frame is received with a payload length field set to less than 46 (42 for VLAN-tagged frames and 38 for frames with stacked VLANs), the zero padding can be removed before the frame is written into the data FIFO depending on the setting of `ENETn_RCR[PADEN]`.

#### Note

If a frame is received with excess padding (in other words, the length field is set as mentioned above, but the frame has more than 64 octets) and padding removal is enabled, then the padding is removed as normal and no error is reported if the frame is otherwise correct (for example: good CRC, less than maximum length, and no other error).

### 11.1.6.4.10 Frame classification (AVB)

To support protocols such as Audio Video Bridging (AVB, IEEE 802.1Qav), normal traffic is separated from time-sensitive traffic immediately at the application interface to allow storing them in different queues for further processing. For every frame received, a classification based on VLAN priority can be performed. When a frame is received, and it contains a VLAN tag, the priority is compared against the values set in the classification match registers (see [Receive Classification Match Register for Class n \(ENET\\_RCMR<sub>n</sub>\)](#)) and the following figure.

Figure 11-6. AVB frame classification

### 11.1.6.4.11 Receive flushing

RX flushing prevents frames in the RX FIFO from being blocked. Blocking can occur if the frame at the head of the RX FIFO cannot be forwarded because the ring it is associated with cannot accept it. This situation occurs when either the ring's `RxBD[EMPTY]` is not set or `ENET_RDARn` is not set. When RX flushing is enabled, via [QoS Scheme \(ENET\\_QOS\)](#), the blocking frame will be flushed (discarded).

### 11.1.6.5 MAC transmit

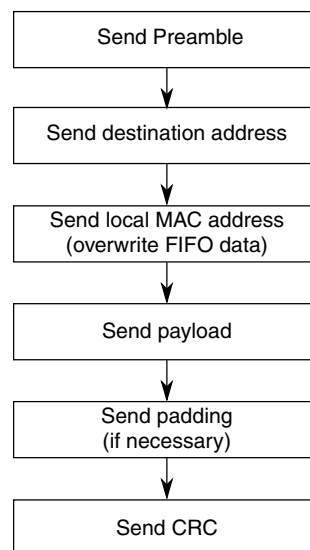

Frame transmission starts when the transmit FIFO holds enough data.

After a transfer starts, the MAC transmit function performs the following tasks:

- Generates preamble and SFD field before frame transmission
- Generates XOFF pause frames if the receive FIFO reports a congestion or if ENET $n$ \_TCR[TFC\_PAUSE] is set with ENET $n$ \_OPD[PAUSE\_DUR] set to a non-zero value
- Generates XON pause frames if the receive FIFO congestion condition is cleared or if TFC\_PAUSE is set with PAUSE\_DUR cleared
- Suspends Ethernet frame transfer (XOFF) if a non-zero pause quanta is received from the MAC receive path
- Adds padding to the frame if required
- Calculates and appends CRC-32 to the transmitted frame
- Sends the frame with correct inter-packet gap (IPG) (deferring)

When the MAC is configured to operate in half-duplex mode, the following additional tasks are performed:

- Collision detection
- Frame retransmit after back-off timer expires

**Figure 11-7. Frame transmit overview**

### 11.1.6.5.1 Frame payload padding

The IEEE specification defines a minimum frame length of 64 bytes.

If the frame sent to the MAC from the user application has a size smaller than 60 bytes, the MAC automatically adds padding bytes (0x00) to comply with the Ethernet minimum frame length specification. Transmit padding is always performed and cannot be disabled.

If the MAC is not allowed to append a CRC (TxBD[TC] = 1), the user application is responsible for providing frames with a minimum length of 64 octets.

### 11.1.6.5.2 MAC address insertion

On each frame received from the core transmit FIFO interface, the source MAC address is either:

- Replaced by the address programmed in the PADDR1/2 fields (ENETn\_TCR[ADDINS] = 1)
- Transparently forwarded to the Ethernet line (ENETn\_TCR[ADDINS] = 0)

### 11.1.6.5.3 CRC-32 generation

The CRC-32 field is optionally generated and appended at the end of a frame.

The CRC polynomial, as specified in the 802.3 standard, is:

- $FCS(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x^1 + 1$

The 32 bits of the CRC value are placed in the FCS field so that the  $x^{31}$  term is the right-most bit of the first octet. The CRC bits are thus transmitted in the following order:  $x^{31}$ ,  $x^{30}$ , ...,  $x^1$ ,  $x^0$ .

### 11.1.6.5.4 Inter-packet gap (IPG)

In full-duplex mode, after frame transmission and before transmission of a new frame, an IPG (programmed in ENETn\_TIPG) is maintained. The minimum IPG can be programmed between 8 and 26 byte-times (64 and 208 bit-times).

In half-duplex mode, the core constantly monitors the line. Actual transmission of the data onto the network occurs only if it has been idle for a 96-bit time period, and any back-off time requirements have been satisfied. In accordance with the standard, the core begins to measure the IPG from CRS/GMII\_CRS de-assertion.

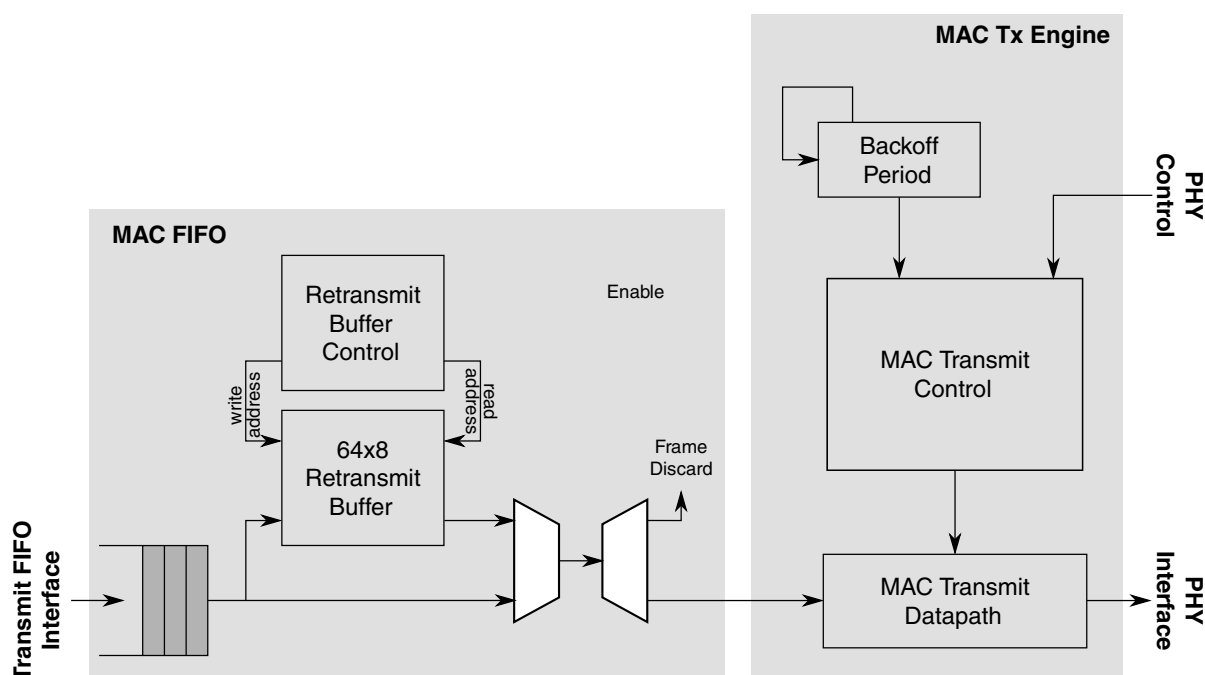

### 11.1.6.5.5 Collision detection and handling — half-duplex operation only

A collision occurs on a half-duplex network when concurrent transmissions from two or more nodes take place. During transmission, the core monitors the line condition and detects a collision when the PHY device asserts COL.

When the core detects a collision while transmitting, it stops transmission of the data and transmits a 32-bit jam pattern. If the collision is detected during the preamble or the SFD transmission, the jam pattern is transmitted after completing the SFD, which results in a minimum 96-bit fragment. The jam pattern is a fixed pattern that is not compared to the actual frame CRC, and has a very low probability (0.532) of having a jam pattern identical to the CRC.

If a collision occurs before transmission of 64 bytes (including preamble and SFD), the MAC core waits for the backoff period and retransmits the packet data (stored in a 64-byte re-transmit buffer) that has already been sent on the line. The backoff period is generated from a pseudo-random process (truncated binary exponential backoff).

If a collision occurs after transmission of 64 bytes (including preamble and SFD), the MAC discards the remainder of the frame, optionally sets the LC interrupt bit, and sets TxBD[LCE].

**Figure 11-8. Packet re-transmit overview**

The backoff time is represented by an integer multiple of slot times. One slot is equal to a 512-bit time period. The number of the delay slot times, before the  $n^{\text{th}}$  re-transmission attempt, is chosen as a uniformly-distributed random integer in the range:

- $0 < r < 2^k$
- $k = \min(n, N)$ ; where  $n$  is the number of retransmissions and  $N = 10$

For example, after the first collision, the backoff period is 0 or 1 slot time. If a collision occurs on the first retransmission, the backoff period is 0, 1, 2, or 3, and so on.

The maximum backoff time (in 512-bit time slots) is limited by  $N = 10$  as specified in the IEEE 802.3 standard.

If a collision occurs after 16 consecutive retransmissions, the core reports an excessive collision condition (ENET $n$ \_EIR[RL] interrupt field and TxBD[EE]) and discards the current packet from the FIFO.

In networks violating the standard requirements, a collision may occur after transmission of the first 64 bytes. In this case, the core stops the current packet transmission and discards the rest of the packet from the transmit FIFO. The core resumes transmission with the next packet available in the core transmit FIFO.

### **warning**

Ethernet PHYs that support the SQE Test, or "heartbeat," feature must disable this feature. When this feature is enabled, the PHY asserts the collision signal after a frame is transmitted to indicate to the ENET that the PHY's collision logic is working. This may cause data corruption in the next frame from the ENET. This corrupted frame contains up to 21 zero bytes which start somewhere within the MAC destination address field. The ENET, however, will still generate a good FCS (CRC-32) but with corrupted data.

#### **11.1.6.5.6 Rate limiting / traffic shaping support**

The MAC-NET supports two methods to optimize frame traffic for either time-sensitive AVB frames (Class A and Class B) or best-effort non-AVB frames:

- Round-robin scheme
- Credit-based traffic shaping

To ensure that sufficient bandwidth is allocated for the AVB frames, the credit-based shaper must be used. Either method can be combined with a time-based shaper to ensure that a frame is always transmitted in its correct time slot.

**Figure 11-9. Transmit arbitration schemes**

#### 11.1.6.5.6.1 Round-robin policy

In the round-robin QoS scheme, each queue is given an equal opportunity to transmit one frame. For example, if queue  $n$  has a frame to transmit, the queue transmits its frame. After queue  $n$  has transmitted its frame, or if queue  $n$  does not have a frame to transmit, queue  $n+1$  is then allowed to transmit its frame, and so on.

#### 11.1.6.5.6.2 Credit-based shaper

The AVB credit based shaper acts independently, per class, to control the bandwidth distribution between normal traffic and time-sensitive traffic with respect to the total link bandwidth available. As per the IEEE 802.1Q, the maximum bandwidth distribution that can be allocated for the time-sensitive frames is 75%. The following example uses 70% for AVB frames and 30% for non-AVB frames:

**Table 11-26. Bandwidth allocation example**

AVB Class A	50%
AVB Class B	20%
non-AVB frames	30%
Total	100%

See [DMA Class Based Configuration \(ENET\\_DMA \$n\$ CFG\)](#) for information on how to allocate bandwidth. The following figure shows how frame traffic is controlled within the MAC-NET core.

### 11.1.6.5.6.3 Time-based shaper

The time-based shaper enables the user to specify when a frame can be transmitted. It is always used in combination with either the round-robin scheme or the credit-based shaper. Use of the time-based shaper can ensure that frames are always transmitted in the correct time slot.

#### 11.1.6.5.6.3.1 Time-based shaper example

Time-based shaping involves the following procedure:

1. Read the current value of the timer. See [Timer Value Register \(ENET\\_ATVR\)](#) and [Adjustable Timer Control Register \(ENET\\_ATCR\)](#).
2. Calculate the frame launch time and write this value to the TLT field of the frame's TxBD. See [Enhanced transmit buffer descriptor](#).
3. Instruct the ENET to use the TLT by setting TxBD[UTLT].

The frame will be fetched and transmitted only if TxBD[TLT] is less than the current value of the timer. In other words, the timer must be past, that is, be greater than, the transmit launch time before the frame will be fetched and transmitted.

The transmit launch time must be not be greater than the current value of ENET\_ATVR + (0.5 × ENET\_ATPER). This means the application can not prepare frames with launch times beyond ENET\_ATVR + (0.5 × ENET\_ATPER). Because ENET\_ATVR wraps, calculate TLT using the equation

$$(ENET\_ATVR + (0.5 \times ENET\_ATPER)) \text{ mod } ENET\_ATPER$$

For example, if ENET\_ATPER is set to the recommended value of 1,000,000,000 ns (one second), then the user must not prepare future frames with launch times greater than (500,000,000 + ENET\_ATVR).

As a specific example, if the current value of ENET\_ATVR is 100,000, then you can prepare the following frames:

1. Frame 1 TxBD[TLT] = 100,000ns + 125,000ns
2. Frame 2 TxBD[TLT] = 100,000ns + 250,000ns
3. And so on

### 11.1.6.6 Full-duplex flow control operation

Three conditions are handled by the core's flow control engine:

- Remote device congestion — The remote device connected to the same Ethernet segment as the core reports congestion and requests that the core stop sending data.

- Core FIFO congestion — When the core's receive FIFO reaches a user-programmable threshold (RX section empty), the core sends a pause frame back to the remote device requesting the data transfer to stop.
- Local device congestion — Any device connected to the core can request (typically, via the host processor) the remote device to stop transmitting data.

#### 11.1.6.6.1 Remote device congestion

When the MAC transmit control gets a valid pause quanta from the receive path and if `ENET $n$ _RCR[FCE]` is set, the MAC transmit logic:

- Completes the transfer of the current frame.
- Stops sending data for the amount of time specified by the pause quanta in 512 bit time increments.
- Sets `ENET $n$ _TCR[RFC_PAUSE]`.

Frame transfer resumes when the time specified by the quanta expires and if no new quanta value is received, or if a new pause frame with a quanta value set to 0x0000 is received. The MAC also resets `RFC_PAUSE` to zero.

If `ENET $n$ _RCR[FCE]` cleared, the MAC ignores received pause frames.

Optionally and independent of `ENET $n$ _RCR[FCE]`, pause frames are forwarded to the client interface if `PAUFWD` is set.

#### 11.1.6.6.2 Local device/FIFO congestion

The MAC transmit engine generates pause frames when the local receive FIFO is not able to receive more than a pre-defined number of words (FIFO programmable threshold) or when pause frame generation is requested by the local host processor.

- To generate a pause frame, the host processor sets `ENET $n$ _TCR[TFC_PAUSE]`. A single pause frame is generated when the current frame transfer is completed and `TFC_PAUSE` is automatically cleared. Optionally, an interrupt is generated.

- An XOFF pause frame is generated when the receive FIFO asserts its section empty flag (internal). An XOFF pause frame is generated automatically, when the current frame transfer completes.
- An XON pause frame is generated when the receive FIFO deasserts its section empty flag (internal). An XON pause frame is generated automatically, when the current frame transfer completes.

When an XOFF pause frame is generated, the pause quanta (payload byte P1 and P2) is filled with the value programmed in ENETn\_OPD[PAUSE\_DUR].

**Figure 11-10. Pause frame generation overview**

**Note**

Although the flow control mechanism should prevent any FIFO overflow on the MAC core receive path, the core receive FIFO is protected. When an overflow is detected on the receive FIFO, the current frame is truncated with an error indication set in the frame status word. The frame should subsequently be discarded by the user application.

**11.1.6.7 Magic packet detection**

Magic packet detection wakes a node that is put in power-down mode by the node management agent. Magic packet detection is supported only if the MAC is configured in sleep mode.

**11.1.6.7.1 Sleep mode**

To put the MAC in Sleep mode, set ENETn\_ECR[SLEEP]. At the same time ENETn\_ECR[MAGICEN] should also be set to enable magic packet detection.

In addition, when the processor is in Stop mode, Sleep mode is entered, without affecting the ENET $n$ \_ECR register bits.

When the MAC is in Sleep mode:

- The transmit logic is disabled.
- The FIFO receive/transmit functions are disabled.
- The receive logic is kept in Normal mode, but it ignores all traffic from the line except magic packets. They are detected so that a remote agent can wake the node.

### 11.1.6.7.2 Magic packet detection

The core is designed to detect magic packets (see [Magic packets](#)) with the destination address set to:

- Any multicast address
- The broadcast address
- The unicast address programmed in PADDR1/2

When a magic packet is detected, EIR[WAKEUP] is set and none of the statistic registers are incremented.

### 11.1.6.7.3 Wakeup

When a magic packet is detected, indicated by ENET $n$ \_EIR[WAKEUP], ENET $n$ \_ECR[SLEEP] should be cleared to resume normal operation of the MAC. Clearing the SLEEP bit automatically masks ENET $n$ \_ECR[MAGICEN], disabling magic packet detection.

## 11.1.6.8 IP accelerator functions

The following sections describe the IP accelerator functions.

### 11.1.6.8.1 Checksum calculation

The IP and ICMP, TCP, UDP checksums are calculated with one's complement arithmetic summing up 16-bit values.

- For ICMP, the checksum is calculated over the complete ICMP datagram, in other words without IP header.
- For TCP and UDP, the checksums contain the header and data sections and values from the IP header, which can be seen as a pseudo-header that is not actually present in the data stream.

**Table 11-27. IPv4 pseudo-header for checksum calculation**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Source address																															
Destination address																															
Zero				Protocol				TCP/UDP length																							

**Table 11-28. IPv6 pseudo-header for checksum calculation**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Source address																															
Destination address																															
TCP/UDP length																															
Zero												Next header																			

The TCP/UDP length value is the length of the TCP or UDP datagram, which is equal to the payload of an IP datagram. It is derived by subtracting the IP header length from the complete IP datagram length that is given in the IP header (IPv4), or directly taken from the IP header (IPv6). The protocol field is the corresponding value from the IP header. The Zero fields are all zeroes.

For IPv6, the complete 128-bit addresses are considered. The next header value identifies the upper layer protocol as either TCP or UDP. It may differ from the next header value of the IPv6 header if extension headers are inserted before the protocol header.

The checksum calculation uses 16-bit words in network byte order: The first byte sent/received is the MSB, and the second byte sent/received is the LSB of the 16-bit value to add to the checksum. If the frame ends on an odd number of bytes, a zero byte is appended for checksum calculation only, and is not actually transmitted.

### 11.1.6.8.2 Additional padding processing

According to IEEE 802.3, any Ethernet frame must have a minimum length of 64 octets.

The MAC usually removes padding on receive when a frame with length information is received. Because IP frames have a type value instead of length, the MAC does not remove padding for short IP frames, as it is not aware of the frame contents.

The IP accelerator function can be configured to remove the Ethernet padding bytes that might follow the IP datagram.

On transmit, the MAC automatically adds padding as necessary to fill any frame to a 64-byte length.

### 11.1.6.8.3 32-bit Ethernet payload alignment

The data FIFOs allow inserting two additional arbitrary bytes in front of a frame. This extends the 14-byte Ethernet header to a 16-byte header, which leads to alignment of the Ethernet payload, following the Ethernet header, on a 32-bit boundary.

This function can be enabled for transmit and receive independently with the corresponding SHIFT16 bits in the ENET $n$ \_TACC and ENET $n$ \_RACC registers.

When enabled, the valid frame data is arranged as shown in [Table 11-29](#).

**Table 11-29. 64-bit interface data structure with SHIFT16 enabled**

63 56	55 48	47 40	39 32	31 24	23 16	15 8	7 0
Byte 5	Byte 4	Byte 3	Byte 2	Byte 1	Byte 0	Any value	Any value
Byte 13	Byte 12	Byte 11	Byte 10	Byte 9	Byte 8	Byte 7	Byte 6
...							

#### 11.1.6.8.3.1 Receive processing

When ENET $n$ \_RACC[SHIFT16] is set, each frame is received with two additional bytes in front of the frame.

The user application must ignore these first two bytes and find the first byte of the frame in bits 23–16 of the first word from the RX FIFO.

#### Note

SHIFT16 must be set during initialization and kept set during the complete operation, because it influences the FIFO write behavior.

#### 11.1.6.8.3.2 Transmit processing

When ENET $n$ \_TACC[SHIFT16] is set, the first two bytes of the first word written (bits 15–0) are discarded immediately by the FIFO write logic.

The SHIFT16 bit can be enabled/disabled for each frame individually if required, but can be changed only between frames.

#### 11.1.6.8.4 Received frame discard

Because the receive FIFO must be operated in store and forward mode (ENET $n$ \_RSFL cleared), received frames can be discarded based on the following errors:

- The MAC function receives the frame with an error:
  - The frame has an invalid payload length
  - Frame length is greater than MAX\_FL
  - Frame received with a CRC-32 error
  - Frame truncated due to receive FIFO overflow
  - Frame is corrupted as PHY signaled an error (RX\_ERR asserted during reception)
- An IP frame is detected and the IP header checksum is wrong
- An IP frame with a valid IP header and a valid IP header checksum is detected, the protocol is known but the protocol-specific checksum is wrong

If one of the errors occurs and the IP accelerator function is configured to discard frames (ENET $n$ \_RACC), the frame is automatically discarded. Statistics are maintained normally and are not affected by this discard function.

#### 11.1.6.8.5 IPv4 fragments

When an IPv4 IP fragment frame is received, only the IP header is inspected and its checksum verified. 32-bit alignment operates the same way on fragments as it does on normal IP frames, as specified above.

The IP fragment frame payload is not inspected for any protocol headers. As such, a protocol header would only exist in the very first fragment. To assist in protocol-specific checksum verification, the one's-complement sum is calculated on the IP payload (all bytes following the IP header) and provided with the frame status word.

The frame fragment status field (RxBBD[FRAG]) is set to indicate a fragment reception, and the one's-complement sum of the IP payload is available in RxBBD[Payload checksum].

## Note

After all fragments have been received and reassembled, the application software can take advantage of the payload checksum delivered with the frame's status word to calculate the protocol-specific checksum of the datagram.

For example, if a TCP payload is delivered by multiple IP fragments, the application software can calculate the pseudo-header checksum value from the first fragment, and add the payload checksums delivered with the status for all fragments to verify the TCP datagram checksum.

### 11.1.6.8.6 IPv6 support

The following sections describe the IPv6 support.

#### 11.1.6.8.6.1 Receive processing

An Ethernet frame of type 0x86DD identifies an IP Version 6 frame (IPv6) frame. If an IPv6 frame is received, the first IP header is inspected (first ten words), which is available in every IPv6 frame.

If the receive SHIFT16 function is enabled, the IP header is aligned on a 32-bit boundary allowing more efficient processing (see [32-bit Ethernet payload alignment](#)).

For TCP and UDP datagrams, the pseudo-header checksum calculation is performed and verified.

To assist in protocol-specific checksum verification, the one's-complement sum is always calculated on the IP payload (all bytes following the IP header) and provided with the frame status word. For example, if extension headers were present, their sums can be subtracted in software from the checksum to isolate the TCP/UDP datagram checksum, if required.

#### 11.1.6.8.6.2 Transmit processing

For IPv6 transmission, the SHIFT16 function is supported to process 32-bit aligned datagrams.

IPv6 has no IP header checksum; therefore, the IP checksum insertion configuration is ignored.

The protocol checksum is inserted only if the next header of the IP header is a known protocol (TCP, UDP, or ICMP). If a known protocol is detected, the checksum over all bytes following the IP header is calculated and inserted in the correct position.

The pseudo-header checksum calculation is performed for TCP and UDP datagrams accordingly.

### **11.1.6.9 Resets and stop controls**

The following sections describe the resets and stop controls.

#### **11.1.6.9.1 Hardware reset**

To reset the Ethernet module, set ENET $n$ \_ECR[RESET].

#### **11.1.6.9.2 Soft reset**

When ENET $n$ \_ECR[ETHER\_EN] is cleared during operation, the following occurs:

- uDMA, buffer descriptor, and FIFO control logic are reset, including the buffer descriptor and FIFO pointers.
- A currently ongoing transmit is terminated by asserting GMII/TXER to the PHY.
- A currently ongoing transmit FIFO write from the application is terminated by stopping the write to the FIFO, and all further data from the application is ignored. All subsequent writes are ignored until re-enabled.
- A currently ongoing receive FIFO read is terminated. The RxBD has arbitrary values in this case.

#### **11.1.6.9.3 Hardware freeze**

When the processor enters debug mode and ECR[DBGGEN] is set, the MAC enters a freeze state where it stops all transmit and receive activities gracefully.

The following happens when the MAC enters hardware freeze:

- A currently ongoing receive transaction on the receive application interface is completed as normal. No further frames are read from the FIFO.
- A currently ongoing transmit transaction on the transmit application interface is completed as normal (in other words, until writing end-of-packet (EOP)).

- A currently ongoing frame receive is completed normally, after which no further frames are accepted from the MII/GMII.
- A currently ongoing frame transmit is completed normally, after which no further frames are transmitted.

#### 11.1.6.9.4 Graceful stop

During a graceful stop, any currently ongoing transactions are completed normally and no further frames are accepted. The MAC can resume from a graceful stop without the need for a reset (for example, clearing ETHER\_EN is not required).

The following conditions lead to a graceful stop of the MAC transmit or receive datapaths.

##### 11.1.6.9.4.1 Graceful transmit stop (GTS)

When gracefully stopped, the MAC is no longer reading frame data from the transmit FIFO and has completed any ongoing transmission.

In any of the following conditions, the transmit datapath stops after an ongoing frame transmission has been completed normally.

- ENET $n$ \_TCR[GTS] is set by software.
- ENET $n$ \_TCR[TFC\_PAUSE] is set by software requesting a pause frame transmission. The status (and register bit) is cleared after the pause frame has been sent.
- A pause frame was received stopping the transmitter. The stopped situation is terminated when the pause timer expires or a pause frame with zero quanta is received.
- MAC is placed in Sleep mode by software or the processor entering Stop mode (see [Sleep mode](#)).
- The MAC is in Hardware Freeze mode.

When the transmitter has reached its stopped state, the following events occur:

- The GRA interrupt is asserted, when transitioned into stopped.
- In Hardware Freeze mode, the GRA interrupt does not wait for the application write completion and asserts when the transmit state machine (in other words, line side of TX FIFO) reaches its stopped state.

#### 11.1.6.9.4.2 Graceful receive stop (GRS)

When gracefully stopped, the MAC is no longer writing frames into the receive FIFO.

The receive datapath stops after any ongoing frame reception has been completed normally, if any of the following conditions occur:

- MAC is placed in Sleep mode either by the software or the processor is in Stop mode). The MAC continues to receive frames and search for magic packets if enabled (see [Magic packet detection](#)). However, no frames are written into the receive FIFO, and therefore are not forwarded to the application.
- The MAC is in Hardware Freeze mode. The MAC does not accept any frames from the MII/GMII.

When the receive datapath is stopped, the following events occur:

- If the RX is in the stopped state, RCR[GRS] is set
- The GRA interrupt is asserted when the transmitter and receiver are stopped
- Any ongoing receive transaction to the application (RX FIFO read) continues normally until the frame end of package (EOP) is reached. After this, the following occurs:
  - When Sleep mode is active, all further frames are discarded, flushing the RX FIFO
  - In Hardware Freeze mode, no further frames are delivered to the application and they stay in the receive FIFO.

#### Note

The assertion of GRS does not wait for an ongoing FIFO read transaction on the application side of the FIFO (FIFO read).

### 11.1.6.9.4.3 Graceful stop interrupt (GRA)

The graceful stopped interrupt (GRA) is asserted for the following conditions:

- In Sleep mode, the interrupt asserts only after both TX and RX datapaths are stopped.
- In Hardware Freeze mode, the interrupt asserts only after both TX and RX datapaths are stopped.
- The MAC transmit datapath is stopped for any other condition (GTS, TFC\_PAUSE, pause received).

The GRA interrupt is triggered only once when the stopped state is entered. If the interrupt is cleared while the stop condition persists, no further interrupt is triggered.

### 11.1.6.10 IEEE 1588 functions

To allow for IEEE 1588 or similar time synchronization protocol implementations, the MAC is combined with a time-stamping module to support precise time-stamping of incoming and outgoing frames. Set `ENETn_ECR[EN1588]` to enable 1588 support.

Figure 11-11. IEEE 1588 functions overview

#### 11.1.6.10.1 Adjustable timer module

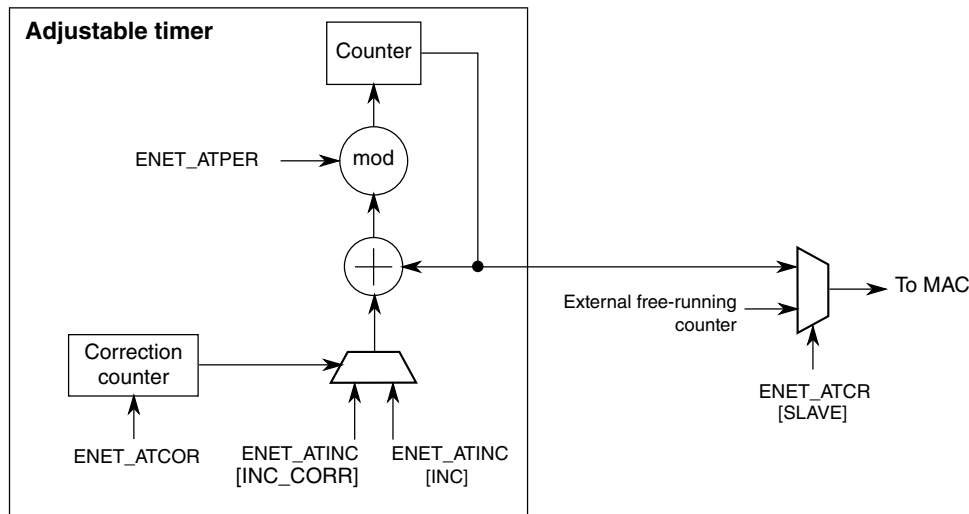

The adjustable timer module (TSM) implements the free-running counter (FRC), which generates the timestamps. The FRC operates with the time-stamping clock, which can be set to any value depending on your system requirements.

Through dedicated correction logic, the timer can be adjusted to allow synchronization to a remote master and provide a synchronized timing reference to the local system. The timer can be configured to cause an interrupt after a fixed time period, to allow synchronization of software timers or perform other synchronized system functions.

The timer is typically used to implement a period of one second; hence, its value ranges from 0 to  $(1 \times 10^9) - 1$ . The period event can trigger an interrupt, and software can maintain the seconds and hours time values as necessary.

#### 11.1.6.10.1.1 Adjustable timer implementation

The adjustable timer consists of a programmable counter/accumulator and a correction counter. The periods of both counters and their increment rates are freely configurable, allowing very fine tuning of the timer.

**Figure 11-12. Adjustable timer implementation detail**

The counter produces the current time. During each time-stamping clock cycle, a constant value is added to the current time as programmed in  $ENET_n\_ATINC$ . The value depends on the chosen time-stamping clock frequency. For example, if it operates at 125 MHz, setting the increment to eight represents 8 ns.

The period, configured in  $ENET_n\_ATPER$ , defines the modulo when the counter wraps. In a typical implementation, the period is set to  $1 \times 10^9$  so that the counter wraps every second, and hence all timestamps represent the absolute nanoseconds within the one second period. When the period is reached, the counter wraps to start again respecting the period modulo. This means it does not necessarily start from zero, but instead the counter is loaded with the value  $(Current + Inc - (1 \times 10^9))$ , assuming the period is set to  $1 \times 10^9$ .

The correction counter operates fully independently, and increments by one with each time-stamping clock cycle. When it reaches the value configured in `ENET $n$ _ATCOR`, it restarts and instructs the timer once to increment by the correction value, instead of the normal value.

The normal and correction increments are configured in `ENET $n$ _ATINC`. To speed up the timer, set the correction increment more than the normal increment value. To slow down the timer, set the correction increment less than the normal increment value.

The correction counter only defines the distance of the corrective actions, not the amount. This allows very fine corrections and low jitter (in the range of 1 ns) independent of the chosen clock frequency.

By enabling slave mode (`ENET $n$ _ATCR[SLAVE] = 1`), the timer is ignored and the current time is externally provided from one of the external modules. See the Chip Configuration details for which clock source is used. This is useful if multiple modules within the system must operate from a single timer. When slave mode is enabled, you still must set `ENET $n$ _ATINC[INC]` to the value of the master, since it is used for internal comparisons.

#### 11.1.6.10.2 Transmit timestamping

Only 1588 event frames need to be time-stamped on transmit. The client application (for example, the MAC driver) should detect 1588 event frames and set `TxBD[TS]` together with the frame.

If `TxBD[TS]` is set, the MAC records the timestamp for the frame in `ENET $n$ _ATSTMP`. `ENET $n$ _EIR[TS_AVAIL]` is set to indicate that a new timestamp is available.

Software implements a handshaking procedure by setting `TxBD[TS]` when it transmits the frame for which a timestamp is needed, and then waits for `ENET $n$ _EIR[TS_AVAIL]` to determine when the timestamp is available. The timestamp is then read from `ENET $n$ _ATSTMP`. This is done for all event frames. Other frames do not use `TxBD[TS]` and, therefore, do not interfere with the timestamp capture.

#### 11.1.6.10.3 Receive timestamping

When a frame is received, the MAC latches the value of the timer when the frame's start of frame delimiter (SFD) field is detected, and provides the captured timestamp on `RxBD[1588 timestamp]`. This is done for all received frames.

#### 11.1.6.10.4 Time synchronization

The adjustable timer module is available to synchronize the local clock of a node to a remote master. It implements a free running 32-bit counter, and also contains an additional correction counter.

The correction counter increases or decreases the rate of the free running counter, enabling very fine granular changes of the timer for synchronization, yet adding only very low jitter when performing corrections.

The application software implements, in a slave scenario, the required control algorithm, setting the correction to compensate for local oscillator drifts and locking the timer to the remote master clock on the network.

The timer and all timestamp-related information should be configured to show the true nanoseconds value of a second (in other words, the timer is configured to have a period of one second). Hence, the values range from 0 to  $(1 \times 10^9) - 1$ . In this application, the seconds counter is implemented in software using an interrupt function that is executed when the nanoseconds counter wraps at  $1 \times 10^9$ .

#### 11.1.6.10.5 Input Capture and Output Compare

The Input Capture Output Compare block can be used to provide precise hardware timing for input and output events.

##### 11.1.6.10.5.1 Input capture

The  $TCCR_n$  capture registers latch the time value when the corresponding external event occurs. An event can be a rising-, falling-, or either-edge of one of the  $1588\_TMR_n$  signals. An event will cause the corresponding  $TCSR_n[TF]$  timer flag to be set, indicating that an input capture has occurred. If the corresponding interrupt is enabled with the  $TCSR_n[TIE]$  field, an interrupt can be generated.

##### 11.1.6.10.5.2 Output compare

The  $TCCR_n$  compare registers are loaded with the time at which the corresponding event should occur. When the ENET free-running counter value matches the output compare reference value in the  $TCCR_n$  register, the corresponding flag,  $TCSR_n[TF]$ , is set, indicating that an output compare has occurred. The corresponding interrupt, if enabled by  $TCSR_n[TIE]$ , will be generated. The corresponding  $1588\_TMR_n$  output signal will be asserted according to  $TCSR_n[TMODE]$ .

### 11.1.6.10.5.3 DMA requests

A DMA request can be enabled by setting  $TCSRn[TDRE]$ . The corresponding DMA request is generated when the  $TCSRn[TF]$  timer flag is set. When the DMA has completed, the corresponding  $TCSRn[TF]$  flag is cleared.

### 11.1.6.11 FIFO thresholds

The core FIFO thresholds are fully programmable to dynamically change the FIFO operation.

For example, store and forward transfer can be enabled by a simple change in the FIFO threshold registers.

The thresholds are defined in 64-bit words.

The receive and transmit FIFOs both have a depth of 1024 words.

#### 11.1.6.11.1 Receive FIFO

Four programmable thresholds are available, which can be set to any value to control the core operation as follows.

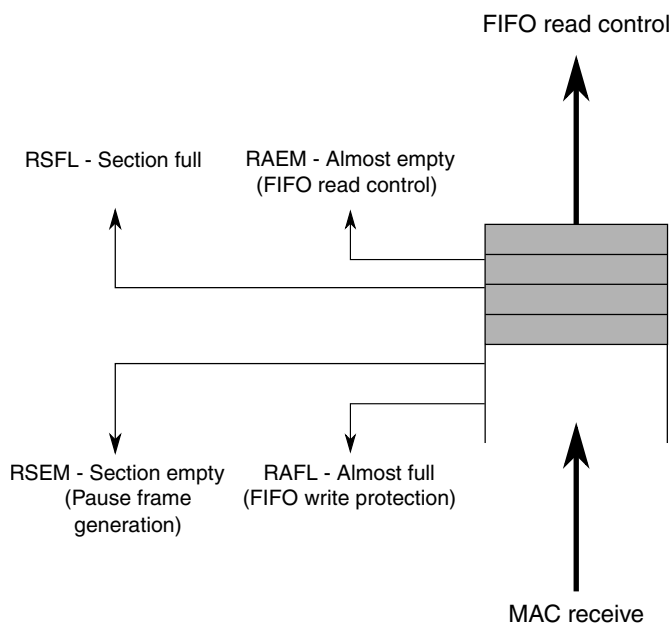

**Table 11-30. Receive FIFO thresholds definition**

Register	Description
ENET $n$ _RSFL [RX_SECTION_F ULL]	<p>When the FIFO level reaches the ENET<math>n</math>_RSFL value, the MAC status signal is asserted to indicate that data is available in the receive FIFO (cut-through operation). Once asserted, if the FIFO empties below the threshold set with ENET<math>n</math>_RAEM and if the end-of-frame is not yet stored in the FIFO, the status signal is deasserted again.</p> <p>If a frame has a size smaller than the threshold (in other words, an end-of-frame is available for the frame), the status is also asserted.</p> <p>To enable store and forward on the receive path, clear ENET<math>n</math>_RSFL. The MAC status signal is asserted only when a complete frame is stored in the receive FIFO.</p> <p>When programming a non-zero value to ENET<math>n</math>_RSFL (cut-through operation) it should be greater than ENET<math>n</math>_RAEM.</p>
ENET $n$ _RAEM [RX_ALMOST_E MPTY]	<p>When the FIFO level reaches the ENET<math>n</math>_RAEM value, and the end-of-frame has not been received, the core receive read control stops the FIFO read (and subsequently stops transferring data to the MAC client application).</p> <p>It continues to deliver the frame, if again more data than the threshold or the end-of-frame is available in the FIFO.</p> <p>Set ENET<math>n</math>_RAEM to a minimum of six.</p>
ENET $n$ _RAFL	<p>When the FIFO level approaches the maximum and there is no more space remaining for at least ENET<math>n</math>_RAFL number of words, the MAC control logic stops writing data in the FIFO and truncates the receive frame to avoid FIFO overflow.</p>

*Table continues on the next page...*

**Table 11-30. Receive FIFO thresholds definition (continued)**

Register	Description
[RX_ALMOST_FULL]	The corresponding error status is set when the frame is delivered to the application. Set ENET <sub>n</sub> _RAFL to a minimum of 4.
ENET <sub>n</sub> _RSEM [RX_SECTION_EMPTY]	When the FIFO level reaches the ENET <sub>n</sub> _RSEM value, an indication is sent to the MAC transmit logic, which generates an XOFF pause frame. This indicates FIFO congestion to the remote Ethernet client. When the FIFO level goes below the value programmed in ENET <sub>n</sub> _RSEM, an indication is sent to the MAC transmit logic, which generates an XON pause frame. This indicates the FIFO congestion is cleared to the remote Ethernet client. Clearing ENET <sub>n</sub> _RSEM disables any pause frame generation.

**Figure 11-13. Receive FIFO overview**

### 11.1.6.11.2 Transmit FIFO

Four programmable thresholds are available which control the core operation as described below.

**Table 11-31. Transmit FIFO thresholds definition**

Register	Description
ENET <sub>n</sub> _TAEM [TX_ALMOST_EMPTY]	When the FIFO level reaches the ENET <sub>n</sub> _TAEM value and no end-of-frame is available for the frame, the MAC transmit logic avoids a FIFO underflow by stopping FIFO reads and transmitting the Ethernet frame with an MII error indication. Set ENET <sub>n</sub> _TAEM to a minimum of 4.
ENET <sub>n</sub> _TAFL [TX_ALMOST_FULL]	When the FIFO level approaches the maximum, so that there is no more space for at least ENET <sub>n</sub> _TAFL number of words, the MAC deasserts its control signal to the application.

*Table continues on the next page...*

**Table 11-31. Transmit FIFO thresholds definition (continued)**

Register	Description
_FULL]	<p>If the application does not react on this signal, the FIFO write control logic avoids FIFO overflow by truncating the current frame and setting the error status. As a result, the frame is transmitted with an GMII/MII error indication.</p> <p>Set ENET<sub>n</sub>_TAFL to a minimum of 4. Larger values allow more latency for the application to react on the MAC control signal deassertion, before the frame is truncated. A typical setting is 8, which offers 3–4 clock cycles of latency to the application to react on the MAC control signal deassertion.</p>
ENET <sub>n</sub> _TSEM [TX_SECTION _EMPTY]	<p>When the FIFO level reaches the ENET<sub>n</sub>_TSEM value, a MAC status signal is deasserted to indicate that the transmit FIFO is getting full. This gives the ENET module an indication to slow or stop its write transaction to avoid a buffer overflow. This is a pure indication function to the application. It has no effect within the MAC.</p> <p>When ENET<sub>n</sub>_TSEM is 0, the signal is never deasserted.</p>
ENET <sub>n</sub> _TFWR	<p>When the FIFO level reaches the ENET<sub>n</sub>_TFWR value and when STRFWD is cleared, the MAC transmit control logic starts frame transmission before the end-of-frame is available in the FIFO (cut-through operation).</p> <p>If a complete frame has a size smaller than the ENET<sub>n</sub>_TFWR threshold, the MAC also transmits the frame to the line.</p> <p>To enable store and forward on the transmit path, set STRFWD. In this case, the MAC starts to transmit data only when a complete frame is stored in the transmit FIFO.</p>

**Figure 11-14. Transmit FIFO overview**

### 11.1.6.12 Loopback options

The core implements external and internal loopback options, which are controlled by the ENET<sub>n</sub>\_RCR register fields found here.

The core implements external and internal loopback options, which are controlled by the following ENET<sub>n</sub>\_RCR register fields:

**Table 11-32. Loopback options**

Register field	Description
LOOP	Internal MII loopback. The MAC transmit is returned to the MAC receive. No data is transmitted to the external interfaces.  In MII internal loopback, MII_TXCLK and MII_RXCLK must be provided with a clock signal (2.5 MHz for 10 Mbit/s, and 25 MHz for 100 Mbit/s))

**Figure 11-15. Loopback options**

### 11.1.6.13 Legacy buffer descriptors

To support the Ethernet controller on previous Freescale devices, legacy FEC buffer descriptors are available. To enable legacy support, clear ENET<sub>n</sub>\_ECR[1588EN].

**NOTE**

- Legacy buffer descriptors are used in single-ring mode, that is, when DMA<sub>n</sub>CFG[DMA\_CLASS\_EN] are zero. In multi-ring mode, legacy TxBDs are used only with the round-robin scheme.
- The legacy buffer descriptor tables show the byte order for little-endian chips. **DBSWP** must be set to 1 after reset to enable little-endian mode.

#### 11.1.6.13.1 Legacy receive buffer descriptor

The following table shows the legacy FEC receive buffer descriptor. [Table 11-36](#) contains the descriptions for each field.

**Table 11-33. Legacy FEC receive buffer descriptor (RxBD)**

	Byte 1								Byte 0							
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Offset + 0	Data length															
Offset + 2	E	RO1	W	RO2	L	—	—	M	BC	MC	LG	NO	—	CR	OV	TR
Offset + 4	Rx data buffer pointer — low halfword															
Offset + 6	Rx data buffer pointer — high halfword															

### 11.1.6.13.2 Legacy transmit buffer descriptor

The following table shows the legacy FEC transmit buffer descriptor. [Table 11-38](#) contains the descriptions for each field.

**Table 11-34. Legacy FEC transmit buffer descriptor (TxBD)**

	Byte 1								Byte 0							
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Offset + 0	Data Length															
Offset + 2	R	TO1	W	TO2	L	TC	ABC <sup>1</sup>	—	—	—	—	—	—	—	—	—
Offset + 4	Tx Data Buffer Pointer — low halfword															
Offset + 6	Tx Data Buffer Pointer — high halfword															

1. This field is not supported by the uDMA.

### 11.1.6.14 Enhanced buffer descriptors

This section provides a description of the enhanced operation of the driver/uDMA via the buffer descriptors.

It is followed by a detailed description of the receive and transmit descriptor fields. To enable the enhanced features, set ENET $n$ \_ECR[1588EN].

#### NOTE

The enhanced buffer descriptor tables show the byte order for little-endian chips. [DBSWP](#) must be set to 1 after reset to enable little-endian mode.

#### 11.1.6.14.1 Enhanced receive buffer descriptor

The following table shows the enhanced uDMA receive buffer descriptor. [Table 11-36](#) contains the descriptions for each field.

**Table 11-35. Enhanced uDMA receive buffer descriptor (RxBd)**

	Byte 1								Byte 0							
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Offset + 0	Data length															
Offset + 2	E	RO1	W	RO2	L	—	—	M	BC	MC	LG	NO	—	CR	OV	TR
Offset + 4	Rx data buffer pointer – low halfword															
Offset + 6	Rx data buffer pointer – high halfword															
Offset + 8	VPCP			—	—	—	—	—	—	—	ICE	PCR	—	VLAN	IPV6	FRA G
Offset + A	ME	—	—	—	—	PE	CE	UC	INT	—	—	—	—	—	—	—

Offset + 1E	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

**Table 11-36. Receive buffer descriptor field definitions**

Word	Field	Description
Offset + 0	0–15 Data Length	Data length. Written by the MAC. Data length is the number of octets written by the MAC into this BD's data buffer if L is cleared (the value is equal to EMRBR), or the length of the frame including CRC if L is set. It is written by the MAC once as the BD is closed.
Offset + 2	0 E	Empty. Written by the MAC (= 0) and user (= 1). 0 The data buffer associated with this BD is filled with received data, or data reception has aborted due to an error condition. The status and length fields have been updated as required. 1 The data buffer associated with this BD is empty, or reception is currently in progress.
Offset + 2	2 RO1	Receive software ownership. This field is reserved for use by software. This read/write field is not modified by hardware, nor does its value affect hardware.
Offset + 2	2 W	Wrap. Written by user. 0 The next buffer descriptor is found in the consecutive location. 1 The next buffer descriptor is found at the location defined in ENET <sub>n</sub> _RDSR.
Offset + 2	3 RO2	Receive software ownership. This field is reserved for use by software. This read/write field is not modified by hardware, nor does its value affect hardware.
Offset + 2	4 L	Last in frame. Written by the uDMA. 0 The buffer is not the last in a frame. 1 The buffer is the last in a frame.
Offset + 2	5–6	Reserved, must be cleared.

Table continues on the next page...

**Table 11-36. Receive buffer descriptor field definitions (continued)**

Word	Field	Description
Offset + 2	7 M	Miss. Written by the MAC. This field is set by the MAC for frames accepted in promiscuous mode, but flagged as a miss by the internal address recognition. Therefore, while in promiscuous mode, you can use the this field to quickly determine whether the frame was destined to this station. This field is valid only if the L and PROM bits are set.  0 The frame was received because of an address recognition hit. 1 The frame was received because of promiscuous mode.  The information needed for this field comes from the promiscuous_miss(ff_rx_err_stat[26]) sideband signal.
Offset + 2	8 BC	Set if the DA is broadcast (FFFF_FFFF_FFFF).
Offset + 2	9 MC	Set if the DA is multicast and not BC.
Offset + 2	10 LG	Receive frame length violation. Written by the MAC. A frame length greater than RCR[MAX_FL] was recognized. This field is valid only if the L field is set. The receive data is not altered in any way unless the length exceeds TRUNC_FL bytes.
Offset + 2	11 NO	Receive non-octet aligned frame. Written by the MAC. A frame that contained a number of bits not divisible by 8 was received, and the CRC check that occurred at the preceding byte boundary generated an error or a PHY error occurred. This field is valid only if the L field is set. If this field is set, the CR field is not set.
Offset + 2	12	Reserved, must be cleared.
Offset + 2	13 CR	Receive CRC or frame error. Written by the MAC. This frame contains a PHY or CRC error and is an integral number of octets in length. This field is valid only if the L field is set.
Offset + 2	14 OV	Overflow. Written by the MAC. A receive FIFO overrun occurred during frame reception. If this field is set, the other status fields, M, LG, NO, and CR, lose their normal meaning and are zero. This field is valid only if the L field is set.
Offset + 2	15 TR	Set if the receive frame is truncated (frame length >TRUNC_FL). If the TR field is set, the frame must be discarded and the other error fields must be ignored because they may be incorrect.
Offset + 4	0–15 Data buffer pointer low	Receive data buffer pointer, low halfword
Offset + 6	0–15 Data buffer pointer high	Receive data buffer pointer, high halfword <sup>1</sup>
Offset + 8	0–2 VPCP	VLAN priority code point. This field is written by the uDMA to indicate the frame priority level. Valid values are from 0 (best effort) to 7 (highest). This value can be used to prioritize different classes of traffic (e.g., voice, video, data). This field is only valid if the L field is set.
Offset + 8	3–9	Reserved, must be cleared.
Offset + 8	10 ICE	IP header checksum error. This is an accelerator option. This field is written by the uDMA. Set when either a non-IP frame is received or the IP header checksum was invalid. An IP frame with less than 3 bytes of payload is considered to be an invalid IP frame. This field is only valid if the L field is set.
Offset + 8	11 PCR	Protocol checksum error. This is an accelerator option. This field is written by the uDMA. Set when the checksum of the protocol is invalid or an unknown protocol is found and checksumming could not be performed. This field is only valid if the L field is set.

*Table continues on the next page...*

**Table 11-36. Receive buffer descriptor field definitions (continued)**

Word	Field	Description
Offset + 8	12	Reserved, must be cleared.
Offset + 8	13 VLAN	VLAN. This is an accelerator option. This field is written by the uDMA. It means that the frame has a VLAN tag. This field is valid only if the L field is set.
Offset + 8	14 IPV6	IPV6 Frame. This field is written by the uDMA. This field indicates that the frame has an IPv6 frame type. If this field is not set it means that an IPv4 or other protocol frame was received. This field is valid only if the L field is set.
Offset + 8	15 FRAG	IPv4 Fragment. This is an accelerator option. This field is written by the uDMA. It indicates that the frame is an IPv4 fragment frame. This field is only valid when the L field is set.
Offset + A	0 ME	MAC error. This field is written by the uDMA. This field means that the frame stored in the system memory was received with an error (typically, a receive FIFO overflow). This field is only valid when the L field is set.
Offset + A	1–4	Reserved, must be cleared.
Offset + A	5 PE	PHY Error. This field is written by the uDMA. Set to "1" when the frame was received with an Error character on the PHY interface. The frame is invalid. This field is valid only when the L field is set.
Offset + A	6 CE	Collision. This field is written by the uDMA. Set when the frame was received with a collision detected during reception. The frame is invalid and sent to the user application. This field is valid only when the L field is set.
Offset + A	7 UC	Unicast. This field is written by the uDMA, and means that the frame is unicast. This field is valid regardless of whether the L field is set.
Offset + A	8 INT	Generate RXB/RXF interrupt. This field is set by the user to indicate that the uDMA is to generate an interrupt on the <i>dma_int_rxb / dma_int_rxfevent</i> .
Offset + A	9–15	Reserved, must be cleared.
Offset + C	0–15 Payload checksum	Internet payload checksum. This is an accelerator option. It is the one's complement sum of the payload section of the IP frame. The sum is calculated over all data following the IP header until the end of the IP payload. This field is valid only when the L field is set.
Offset + E	0–4 Header length	Header length. This is an accelerator option. This field is written by the uDMA. This field is the sum of 32-bit words found within the IP and its following protocol headers. If an IP datagram with an unknown protocol is found, then the value is the length of the IP header. If no IP frame or an erroneous IP header is found, the value is 0. The following values are minimum values if no header options exist in the respective headers: <ul style="list-style-type: none"> <li>• ICMP/IP: 6 (5 IP header, 1 ICMP header)</li> <li>• UDP/IP: 7 (5 IP header, 2 UDP header)</li> <li>• TCP/IP: 10 (5 IP header, 5 TCP header)</li> </ul> This field is only valid if the L field is set.
Offset + E	5–7	Reserved, must be cleared.
Offset + E	8–15 Protocol type	Protocol type. This is an accelerator option. The 8-bit protocol field found within the IP header of the frame. It is valid only when ICE is cleared. This field is valid only when the L field is set.
Offset + 10	0–15	Reserved, must be cleared.
Offset + 12	0 BDU	Last buffer descriptor update done. Indicates that the last BD data has been updated by uDMA. This field is written by the user (=0) and uDMA (=1).

Table continues on the next page...

**Table 11-36. Receive buffer descriptor field definitions (continued)**

Word	Field	Description
Offset + 12	1–15	Reserved, must be cleared.
Offset + 14	0–15	This value is written by the uDMA. It is only valid if the L field is set.
Offset + 16	1588 timestamp	
Offset + 18 – Offset + 1E	0–15	Reserved, must be cleared.

- The receive buffer pointer, containing the address of the associated data buffer, must always be evenly divisible by 64. The buffer must reside in memory external to the MAC. The Ethernet controller never modifies this value.

### 11.1.6.14.2 Enhanced transmit buffer descriptor

**Table 11-37. Enhanced transmit buffer descriptor (TxBD)**

	Byte 1								Byte 0							
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Offset + 0	Data length															
Offset + 2	R	TO1	W	TO2	L	TC	—	—	—	—	—	—	—	—	—	—
Offset + 4	Tx Data Buffer Pointer – low halfword															
Offset + 6	Tx Data Buffer Pointer – high halfword

Offset + A	—	INT	TS	PINS	IINS	—	—	UTLT	FTYPE				—	—	—	—
Offset + C	TLT – low halfword															
Offset + E	TLT – high halfword															
Offset + 10	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Offset + 12	BDU	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Offset + 14	1588 timestamp – low halfword															
Offset + 16	1588 timestamp – high halfword															
Offset + 18	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Offset + 1A	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Offset + 1C	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Offset + 1E	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

**Table 11-38. Enhanced transmit buffer descriptor field definitions**

Word	Field	Description
Offset + 0	0–15	Data length, written by user.
	Data Length	Data length is the number of octets the MAC should transmit from this BD's data buffer. It is never modified by the MAC.
Offset + 2	0	Ready. Written by the MAC and you.

*Table continues on the next page...*

**Table 11-38. Enhanced transmit buffer descriptor field definitions (continued)**

Word	Field	Description
	R	0 The data buffer associated with this BD is not ready for transmission. You are free to manipulate this BD or its associated data buffer. The MAC clears this field after the buffer has been transmitted or after an error condition is encountered. 1 The data buffer, prepared for transmission by you, has not been transmitted or currently transmits. You may write no fields of this BD after this field is set.
Offset + 2	1 TO1	Transmit software ownership. This field is reserved for software use. This read/write field is not modified by hardware and its value does not affect hardware.
Offset + 2	2 W	Wrap. Written by user. 0 The next buffer descriptor is found in the consecutive location 1 The next buffer descriptor is found at the location defined in ETDSR.
Offset + 2	3 TO2	Transmit software ownership. This field is reserved for use by software. This read/write field is not modified by hardware and its value does not affect hardware.
Offset + 2	4 L	Last in frame. Written by user. 0 The buffer is not the last in the transmit frame 1 The buffer is the last in the transmit frame
Offset + 2	5 TC	Transmit CRC. Written by user, and valid only when L is set. 0 End transmission immediately after the last data byte 1 Transmit the CRC sequence after the last data byte This field is valid only when the L field is set.
Offset + 2	6 ABC	Append bad CRC. <b>Note:</b> This field is not supported by the uDMA and is ignored.
Offset + 2	7–15	Reserved, must be cleared.
Offset + 4	0–15 Data buffer pointer low	Tx data buffer pointer, low halfword
Offset + 6	0–15 Data buffer pointer high	Tx data buffer pointer, high halfword. The buffer must reside in memory external to the MAC. This value is never modified by the Ethernet controller. <b>NOTE:</b> For optimal performance, make the transmit buffer pointer evenly divisible by 64.
Offset + 8	0 TXE	Transmit error occurred. This field is written by the uDMA. This field indicates that there was a transmit error of some sort reported with the frame. Effectively this field is an OR of the other error fields including UE, EE, FE, LCE, OE, and TSE. This field is valid only when the L field is set.
Offset + 8	1	Reserved, must be cleared.
Offset + 8	2 UE	Underflow error. This field is written by the uDMA. This field indicates that the MAC reported an underflow error on transmit. This field is valid only when the L field is set.
Offset + 8	3 EE	Excess Collision error. This field is written by the uDMA. This field indicates that the MAC reported an excess collision error on transmit. This field is valid only when the L field is set.

*Table continues on the next page...*

**Table 11-38. Enhanced transmit buffer descriptor field definitions (continued)**

Word	Field	Description
Offset + 8	4 FE	Frame with error. This field is written by the uDMA. This field indicates that the MAC reported that the uDMA reported an error when providing the packet. This field is valid only when the L field is set.
Offset + 8	5 LCE	Late collision error. This field is written by the uDMA. This field indicates that the MAC reported that there was a Late Collision on transmit. This field is valid only when the L field is set.
Offset + 8	6 OE	Overflow error. This field is written by the uDMA. This field indicates that the MAC reported that there was a FIFO overflow condition on transmit. This field is only valid when the L field is set.
Offset + 8	7 TSE	Timestamp error. This field is written by the uDMA. This field indicates that the MAC reported a different frame type than a timestamp frame. This field is valid only when the L field is set.
Offset + 8	8–15	Reserved, must be cleared.
Offset + A	0	Reserved, must be cleared.
Offset + A	1 INT	Generate interrupt flags. This field is written by the user. This field is valid regardless of the L field and must be the same for all EBD for a given frame. The uDMA does not update this value.
Offset + A	2 TS	Timestamp. This field is written by the user. This indicates that the uDMA is to generate a timestamp frame to the MAC. This field is valid regardless of the L field and must be the same for all EBD for the given frame. The uDMA does not update this value.
Offset + A	3 PINS	Insert protocol specific checksum. This field is written by the user. If set, the MAC's IP accelerator calculates the protocol checksum and overwrites the corresponding checksum field with the calculated value. The checksum field must be cleared by the application generating the frame. The uDMA does not update this value. This field is valid regardless of the L field and must be the same for all EBD for a given frame.
Offset + A	4 IINS	Insert IP header checksum. This field is written by the user. If set, the MAC's IP accelerator calculates the IP header checksum and overwrites the corresponding header field with the calculated value. The checksum field must be cleared by the application generating the frame. The uDMA does not update this value. This field is valid regardless of the L field and must be the same for all EBD for a given frame.
Offset + A	5–6	Reserved, must be cleared.
Offset + A	7 UTLT	Use transmit launch time. If set to 1, TLT high and low values are used to determine if frame can be transmitted. This field must only be set in the <i>first</i> BD of a frame. TLT is always used in combination with either the round-robin scheme or the credit-based shaper.  TLT can be used with a single BD queue. However, at least one DMA class, <code>DMAnCFG[DMA_CLASS_EN]</code> must be enabled. For example, to use TLT with only queue 0, enable one of the <code>DMAnCFG[DMA_CLASS_EN]</code> fields and clear both TDAR1 and TDAR2. Although this enables multi-queue, only the single queue 0 is used.
Offset + A	8–11 FTYPE	Type of frame to be transmitted. If a credit-based scheme is used, this field must match the BD ring queue.  0x0 – Non-AVB. Corresponds to ENET_TDSR. 0x1 – AVB Class A. Corresponds to ENET_TDSR1. 0x2 – AVB Class B. Corresponds to ENET_TDSR2.

*Table continues on the next page...*

**Table 11-38. Enhanced transmit buffer descriptor field definitions (continued)**

Word	Field	Description
		All other values are reserved.
Offset + A	12–15	Reserved, must be cleared.
Offset + C	0–15 TLT low	Transmit launch time low. Low two bytes of time value that specifies when frame can be transmitted.
Offset + E	0–15 TLT high	Transmit launch time high. High two bytes of time value that specifies when frame can be transmitted.
Offset + 10	0–15	Reserved, must be cleared.
Offset + 12	0 BDU	Last buffer descriptor update done. Indicates that the last BD data has been updated by uDMA. This field is written by the user (=0) and uDMA (=1).
Offset + 12	1–15	Reserved, must be cleared.
Offset + 14	0–15	This value is written by the uDMA . It is valid only when the L field is set.
Offset + 16	1588 timestamp	
Offset + 18–Offset + 1E	0–15	Reserved, must be cleared.

### 11.1.6.15 Client FIFO application interface

The FIFO interface is completely asynchronous from the Ethernet line, and the transmit and receive interface can operate at a different clock rate.

All transfers to/from the user application are handled independently of the core operation, and the core provides a simple interface to user applications based on a two-signal handshake.

#### 11.1.6.15.1 Data structure description

The data structure defined in the following tables for the FIFO interface must be respected to ensure proper data transmission on the Ethernet line. Byte 0 is sent to and received from the line first.

**Table 11-39. FIFO interface data structure**

	63	56 55	48 47	40 39	32 31	24 23	16 15	8 7	0
Word 0	Byte 7	Byte 6	Byte 5	Byte 4	Byte 3	Byte 2	Byte 1	Byte 0	
Word 1	Byte 15	Byte 14	Byte 13	Byte 12	Byte 11	Byte 10	Byte 9	Byte 8	
...	...								

The size of a frame on the FIFO interface may not be a modulo of 64-bit.

The user application may not care about the Ethernet frame formats in full detail. It needs to provide and receive an Ethernet frame with the following structure:

- Ethernet MAC destination address
- Ethernet MAC source address
- Optional 802.1q VLAN tag (VLAN type and info field)
- Ethernet length/type field
- Payload

Frames on the FIFO interface do not contain preamble and SFD fields, which are inserted and discarded by the MAC on transmit and receive, respectively.

- On receive, CRC and frame padding can be stripped or passed through transparently.
- On transmit, padding and CRC can be provided by the user application, or appended automatically by the MAC independently for each frame. No size restrictions apply.

### Note

On transmit, if `ENETn_TCR[ADDINS]` is set, bytes 6–11 of each frame can be set to any value, since the MAC overwrites the bytes with the MAC address programmed in the `ENETn_PAUR` and `ENETn_PALR` registers.

**Table 11-40. FIFO interface frame format**

Byte number	Field
0–5	Destination MAC address
6–11	Source MAC address
12–13	Length/type field
14–N	Payload data

VLAN-tagged frames are supported on both transmit and receive, and implement additional information (VLAN type and info).

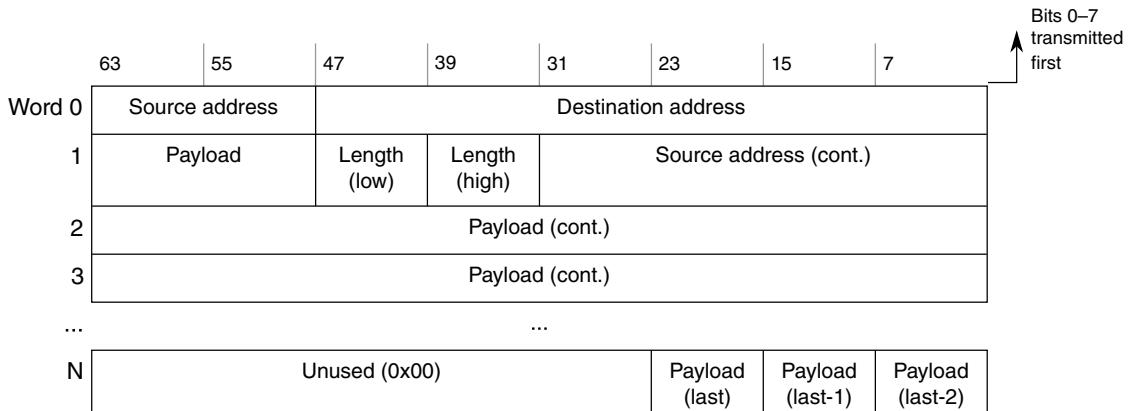

**Table 11-41. FIFO interface VLAN frame format**

Byte number	Field
0–5	Destination MAC address
6–11	Source MAC address
12–15	VLAN tag and info
16–17	Length/type field
18–N	Payload data

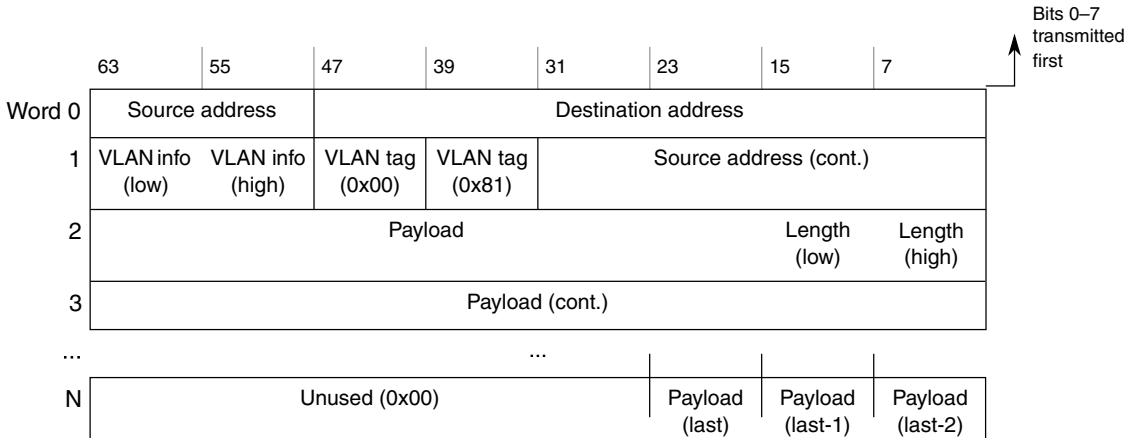

**Note**

The standard defines that the LSB of the MAC address is sent/received first, while for all the other header fields — in other words, length/type, VLAN tag, VLAN info, and pause quanta — the MSB is sent/received first.

**11.1.6.15.2 Data structure examples**

**Figure 11-16. Normal Ethernet frame 64-bit mapping example**

**Figure 11-17. VLAN-tagged frame 64-bit mapping example**

If CRC forwarding is enabled (CRCFWD = 0), the last four valid octets of the frame contain the FCS field. The non-significant bytes of the last word can have any value.

**11.1.6.15.3 Frame status**

A MAC layer status word and an accelerator status word is available in the receive buffer descriptor.

See [Enhanced buffer descriptors](#) for details.

The status is available with each frame with the last data of the frame.

If the frame status contains a MAC layer error (for example, CRC or length error), RxBD[ME] is also set with the last data of the frame.

### 11.1.6.16 FIFO protection

The following sections describe the FIFO protection mechanisms.

#### 11.1.6.16.1 Transmit FIFO underflow

During a frame transfer, when the transmit FIFO reaches the almost empty threshold with no end-of-frame indication stored in the FIFO, the MAC logic:

- Stops reading data from the FIFO
- Asserts the MII error signal (MII\_TXER) (1 in [Figure 11-18](#)) to indicate that the fragment already transferred is not valid
- Deasserts the MII transmit enable signal (MII\_TXEN) to terminate the frame transfer (2)

After an underflow, when the application completes the frame transfer (3), the MAC transmit logic discards any new data available in the FIFO until the end of packet is reached (4) and sets the enhanced TxBD[UE] field.

The MAC starts to transfer data on the MII interface when the application sends a new frame with a start of frame indication (5).

Figure 11-18. Transmit FIFO underflow protection

### 11.1.6.16.2 Transmit FIFO overflow

On the transmit path, when the FIFO reaches the programmable almost full threshold, the internal MAC ready signal is deasserted. The application should stop sending new data.

However, if the application keeps sending data, the transmit FIFO overflows, corrupting contents that were previously stored. The core logic sets the enhanced TxBD[OE] field for the next frame transmitted to indicate this overflow occurrence.

#### Note

Overflow is a fatal error and must be addressed by resetting the core or clearing ENET $_n$ \_ECR[ETHER\_EN], to clear the FIFOs and prepare for normal operation again.

### 11.1.6.16.3 Receive FIFO overflow

During a frame reception, if the client application is not able to receive data (1), the MAC receive control truncates the incoming frame when the FIFO reaches the programmable almost-full threshold to avoid an overflow.

The frame is subsequently received on the FIFO interface with an error indication (enhanced RxBD[ME] field set together with receive end-of-packet) (2) with the truncation error status field set (3).

Figure 11-19. Receive FIFO overflow protection

### 11.1.6.17 PHY management interface

The MDIO interface is a two-wire management interface. The MDIO management interface implements a standardized method to access the PHY device management registers.

The core implements a master MDIO interface, which can be connected to up to 32 PHY devices.

#### 11.1.6.17.1 MDIO clause 22 frame format

The core MDIO master controller communicates with the slave (PHY device) using frames that are defined in the following table.

A complete frame has a length of 64 bits made up of an optional 32-bit preamble, 14-bit command, 2-bit bus direction change, and 16-bit data. Each bit is transferred on the rising edge of the MDIO clock (MDC signal). The MDIO data signal is tri-stated between frames.

The core PHY management interface supports the standard MDIO specification (IEEE 802.3 Clause 22).

**Table 11-42. MDIO clause 22 frame structure**

ST	OP	PHYADR	REGADR	TA	DATA
----	----	--------	--------	----	------

**Table 11-43. MDIO frame field descriptions**

Field	Description
ST (2 bits)	Start indication field, programmed with ENET <sub>n</sub> _MMFR[ST] and equal to 01 for Standard MDIO (Clause 22).
OP (2 bits)	Opcode defines type of operation. Programmed with ENET <sub>n</sub> _MMFR[OP]. 01 Write operation 10 Read operation
PHYADR (5 bits)	Five-bit PHY device address, programmed with ENET <sub>n</sub> _MMFR[PA]. Up to 32 devices can be addressed.
REGADR (5 bits)	Five-bit register address, programmed with ENET <sub>n</sub> _MMFR[RA]. Each PHY can implement up to 32 registers.
TA (2 bits)	Turnaround time, programmed with ENET <sub>n</sub> _MMFR[TA]. Two bit-times are reserved for read operations to switch the data bus from write to read. The PHY device presents its register contents in the data phase and drives the bus from the second bit of the turnaround phase.
Data (16 bits)	Data, set by ENET <sub>n</sub> _MMFR[DATA]. Written to or read from the PHY

### 11.1.6.17.2 MDIO clause 45 frame format

The extended MDIO frame structure defined in IEEE 802.3 Clause 45 introduces indirect addressing. First, a write transaction to an address register is done, followed by a write or read transaction which will put the 16-bit data in the register or retrieve the register contents respectively. A preamble of 32 bits of logical ones is sent prior to every transaction. The MDIO data signal is tri-stated between frames.

The extended MDIO defines four transactions, which are determined by the two-bit opcode field.

**Table 11-44. MDIO clause 45 frame structure**

ST	OP	PRTAD	DEVAD	TA	ADDR/DATA
----	----	-------	-------	----	-----------

All bits are transmitted from left to right (Preamble bits first) and all fields have their Most-Significant bit sent first (leftmost in above table). The complete frame has a length of 64 bits (32-bit preamble, 14-bit command, 2-bit bus direction change, 16-bit data). Each bit is transferred with the rising edge of the MDIO clock (MDC).

The fields and transactions are summarized in the following tables.

**Table 11-45. MDIO clause 45 frame field descriptions**

Field	Description
ST	Start indication. Indicates the end of the preamble and start of the frame. This value is 00 for extended MDIO (Clause 45) frames.
OP	Opcode defines if a read or write operation is performed and is programmed with ENET $n$ _MMFR[OP]. See <a href="#">Table 11-46</a> for more information. 00 Address write 01 Write operation 10 Read inc. operation 11 Read operation
PRTAD	The port address specifies a MDIO port. Each Port can have up to 32 devices which each can have a separate set of registers.
DEVAD	Device address. Up to 32 devices can be addressed (within a port).
TA	Turnaround time, programmed with ENET $n$ _MMFR[TA]. Two bit-times are reserved for read operations to switch the data bus from write to read. The PHY device presents its register contents in the data phase and drives the bus from the second bit of the turnaround phase.
ADDR/DATA	16-bit address (for address write) or data, set by ENET $n$ _MMFR[DATA], written to or read from the PHY.

**Table 11-46. MDIO Clause 45 Transactions**

Transaction Type	Description
Address	A write transaction to the internal address register of the device/port. The data section of the frame contains the value to be stored in the device's internal address "pointer" register for further transactions.
Write	Data write to a register. The 16 bit data will be written to the register identified by the device-internal address.
Read	Data is read from the register identified by the device-internal address.
Read inc.	Read with address postincrement. The register identified by the device-internal address is read. After this, the device-internal address is incremented. If the address register is all '1' (0xFFFF) no increment is done (i.e. increment does not wrap around).

### 11.1.6.17.3 MDIO clock generation

The MDC clock is generated from the internal bus clock (i.e., IPS bus clock) divided by the value programmed in ENET $n$ \_MSCR[MII\_SPEED].

### 11.1.6.17.4 MDIO operation

To perform an MDIO access, set the MDIO command register (ENET $n$ \_MMFR) according to the description provided in MII Management Frame Register (ENET $n$ \_MMFR).

To check when the programmed access completes, read the ENET $n$ \_EIR[MII] field.

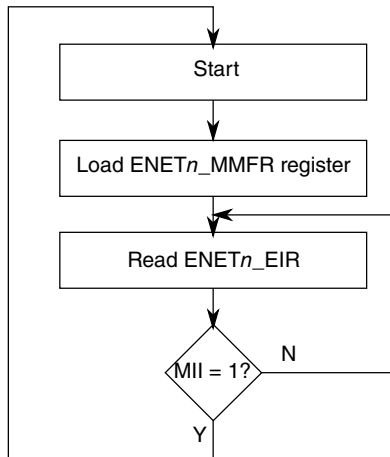

Figure 11-20. MDIO access overview

### 11.1.6.18 Ethernet interfaces

The following Ethernet interfaces are implemented:

- Fast Ethernet MII (Media Independent Interface)
- RMII 10/100 using interface converters/gaskets
- RGMII 10/100/1000 by way of interface converters/gaskets

The following table shows how to configure ENET registers to select each interface.

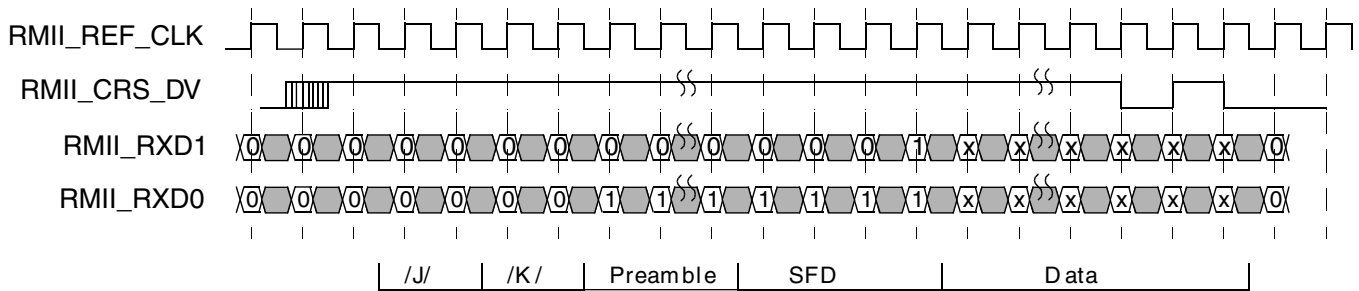

Mode	ECR[SPEED]	RCR[RMII_10T]	RCR[RMII_MODE]	RCR[RGMIEN]
MII - 10 Mbit/s	0	—	0	0
MII - 100 Mbit/s	0	—	0	0
RMII - 10 Mbit/s	0	1	1	0
RMII - 100 Mbit/s	0	0	1	0
RGMII - 10 Mbit/s	0	1	0	1
RGMII - 100 Mbit/s	0	0	0	1
RGMII - 1000 Mbit/s	1	—	0	1

### 11.1.6.18.1 RMII interface

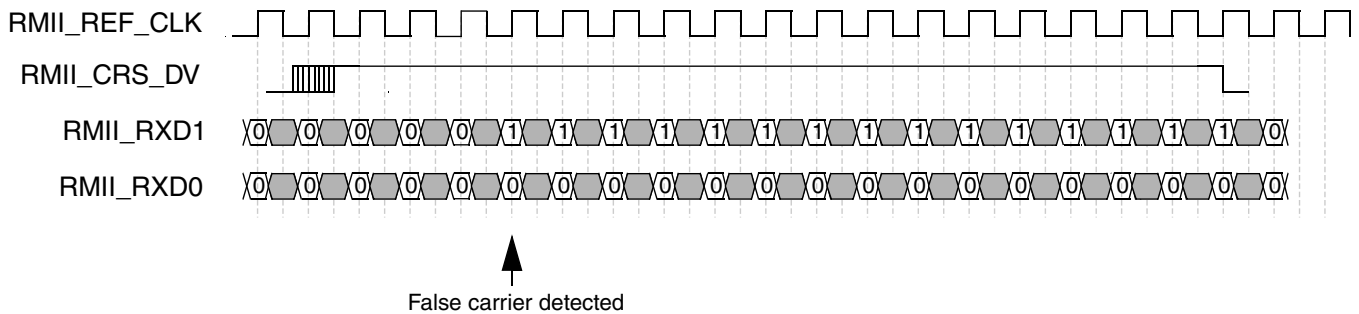

In RMII receive mode, for normal reception following assertion of CRS\_DV, RXD[1:0] is 00 until the receiver determines that the receive event has a proper start-of-stream delimiter (SSD).

The preamble appears (RXD[1:0]=01) and the MACs begin capturing data following detection of SFD.

**Figure 11-21. RMII receive operation**

If a false carrier is detected (bad SSD), then RXD[1:0] is 10 until the end of the receive event. This is a unique pattern since a false carrier can only occur at the beginning of a packet where the preamble is decoded (RXD[1:0] = 01).

**Figure 11-22. RMII receive operation with false carrier**

In RMII transmit mode, TXD[1:0] provides valid data for each REF\_CLK period while TXEN is asserted.

**Figure 11-23. RMII transmit operation**

### 11.1.6.18.2 RGMII interface

In RGMII modes, the data and control information is multiplexed by taking advantage of both edges of the reference clocks.

The data signals contain the lower four data bits on the rising edge and the upper four bits on the falling edge. The control signals are multiplexed into a single clock cycle using the same technique.

**Figure 11-24. RGMII transmit operation**

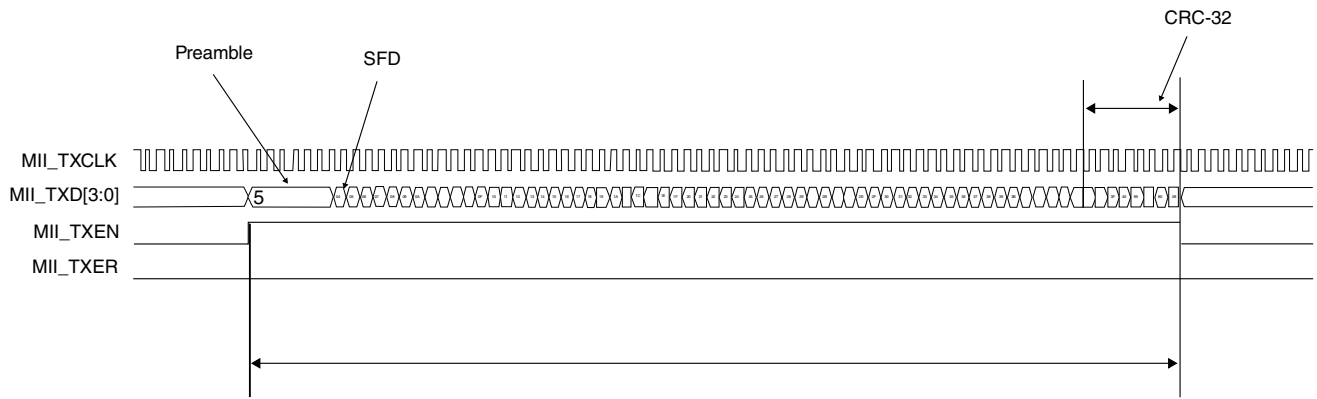

**Figure 11-25. RGMII receive operation**

### 11.1.6.18.3 MII Interface — transmit

On transmit, all data transfers are synchronous to MII\_TXCLK rising edge. The MII data enable signal MII\_TXEN is asserted to indicate the start of a new frame, and remains asserted until the last byte of the frame is present on the MII\_TXD[3:0] bus.

Between frames, MII\_TXEN remains deasserted.

**Figure 11-26. MII transmit operation**

If a frame is received on the FIFO interface with an error (for example, RxBD[ME] set) the frame is subsequently transmitted with the MII\_TXER error signal for one clock cycle at any time during the packet transfer.

**Figure 11-27. MII transmit operation — errored frame**

### 11.1.6.18.3.1 Transmit with collision — half-duplex

When a collision is detected during a frame transmission (MII\_COL asserted), the MAC stops the current transmission, sends a 32-bit jam pattern, and re-transmits the current frame.

(See [Collision detection in half-duplex mode](#) for details)

Figure 11-28. MII transmit operation — transmission with collision

### 11.1.6.18.4 MII interface — receive

On receive, all signals are sampled on the MII\_RXCLK rising edge. The MII data enable signal, MII\_RXDV, is asserted by the PHY to indicate the start of a new frame and remains asserted until the last byte of the frame is present on MII\_RXD[3:0] bus.

Between frames, MII\_RXDV remains deasserted.

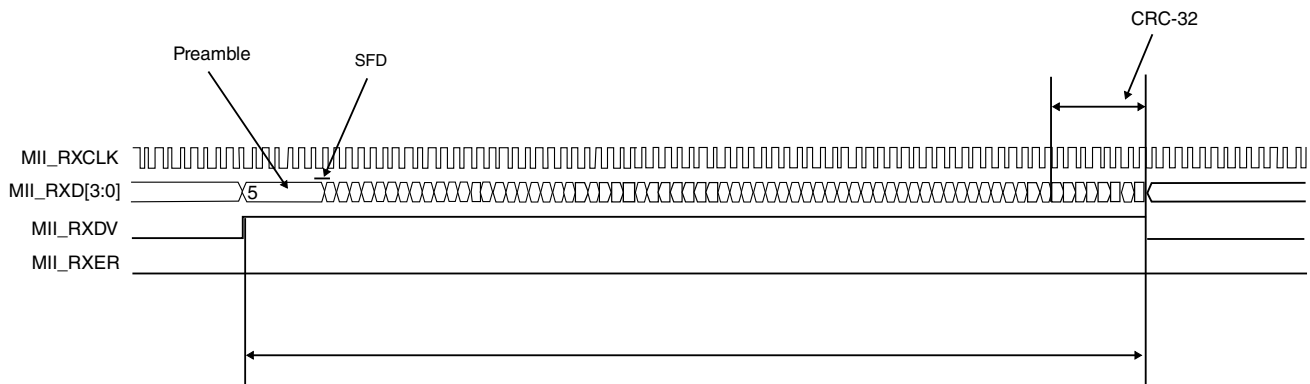

Figure 11-29. MII receive operation

If the PHY detects an error on the frame received from the line, the PHY asserts the MII error signal, MII\_RXER, for at least one clock cycle at any time during the packet transfer.

**Figure 11-30. MII receive operation — errored frame**

A frame received on the MII interface with a PHY error indication is subsequently transferred on the FIFO interface with RxBD[ME] set.

### 11.1.6.19 AVB configuration

The following steps give an example of how to initialize the ENET module for AVB.

1. Set up ENET\_QOS:
  - Set TX\_SCHEME to 000b, credit-based scheme.
  - Set RX\_FLUSH0 to 1, enable RX flush for ring 0.
2. Set up TX BD ring and RX BD ring for each queue, 0-2.
  - Program ENET\_MRBR, ENET\_TDSR, and ENET\_RDSR.
  - Program ENET\_MRBR1, ENET\_TDSR1, and ENET\_RDSR1.
  - Program ENET\_MRBR2, ENET\_TDSR2, and ENET\_RDSR2.
  - Program each TX and RX BD ring queue for all classes used in memory.

#### NOTE

If using credit-based scheme, ensure that enhanced transmit buffer descriptor FTYPE field matches BD ring queue, for example:

- FTYPE = 0h corresponds to ENET\_TDSR
- FTYPE = 1h corresponds to ENET\_TDSR1
- FTYPE = 2h corresponds to ENET\_TDSR2

3. Program ENET\_DMA1CFG and ENET\_DMA2CFG for class 1 and class 2 corresponding to BD ring queue 1 and 2. DMA\_CLASS\_EN must be set to one for

that class to be enabled. See [DMA Class Based Configuration \(ENET\\_DMA \$n\$ CFG\)](#) for information on how to program IDLE\_SLOPE.

4. Program ENET\_RCMR1 and ENET\_RCMR2 for class 1 and class 2 matching for receive.

### NOTE

Even if a match occurs, if ENET\_DMA $n$ CFG[DMA\_CLASS\_EN] is zero for the corresponding class, the RX frame will be automatically forwarded to BD ring queue 0.

5. Program the other ENET registers according to application requirements.
6. Program ENET\_RDAR, ENET\_RDAR1, ENET\_RDAR2, ENET\_TDAR, ENET\_TDAR1, and ENET\_TDAR2 to 0100\_0000h according to the classes used.
7. Set ENET\_ECR[ETHEREN] to one.

## 11.1.6.20 Interrupt coalescence

The purpose of the interrupt coalescing is to reduce the number of interrupts generated by the MAC so as to reduce the CPU loading.

To facilitate this interrupt coalescing for each queue, these registers are available with the same control and configuration fields.

- [Transmit Interrupt Coalescing Register \(ENET\\_TXIC \$n\$ \)](#) where  $n=0,1,2$  for queue/class 0,1,2.
- [Receive Interrupt Coalescing Register \(ENET\\_RXIC \$n\$ \)](#) where  $n=0,1,2$  for queue/class 0,1,2.

When coalescing is enabled by asserting the corresponding ICEN field and such interrupt is also enabled by the corresponding interrupt mask of the EIMR register, the MAC generates an interrupt when the threshold number of frames is reached (defined by ICFT) or when the threshold timer expires (defined by ICTT).

When coalescing is disabled by de-asserting ICEN, but interrupt is enabled by the corresponding interrupt mask of the EIMR register, the MAC generates an interrupt as they are received without using coalescing. Interrupt coalescing is done for each transmit and receive queue/class independently.

### 11.1.6.20.1 Interrupt coalescence setup

Interrupt coalescence supports both legacy and enhanced BDs. The following guidelines are recommended when setting up interrupt coalescence.

- When the MAC is configured for enhanced (IEEE 1588) mode, that is, enhanced BDs:
  - Set the INT bit in the enhanced received buffer descriptor to one.
  - Set the INT bit in the enhanced transmit buffer descriptor(s) to one.
- Clear the RXB, RXB1, and RXB2 fields in the EIMR register.
- Clear the TXB, TXB1, and TXB2 fields in the EIMR register.

#### 11.1.6.20.2 Updating the frame count threshold on-the-fly

To update the ICFT field in the RXIC $n$  and TXIC $n$  registers:

1. Disable interrupt coalescence by clearing the appropriate ICEN field. This will allow the internal interrupt coalescence counter to reset to zero.

#### NOTE

When disabling interrupt coalescence, if an interrupt event is pending, that is, the interrupt counter is not zero, then an interrupt will occur.

2. Write the new threshold value to the ICFT field.
3. Set ICEN to one.

#### NOTE

The ICFT field can be updated on-the-fly without disabling the ICEN field. The hardware interrupt will continue and there is a possibility that an interrupt will occur depending on the state of the hardware counter and the previous ICFT value.

#### 11.1.6.20.3 Updating the timer threshold on-the-fly

To update the ICTT field in the RXIC $n$  and TXIC $n$  registers:

1. Disable interrupt coalescence by clearing the appropriate ICEN field. This will allow the internal interrupt coalescence counter to reset to zero.

#### NOTE

When disabling interrupt coalescence, if an interrupt event is pending, that is, the interrupt counter is not zero, then an interrupt will occur.

2. Write the new timer value to the ICTT field.
3. Set ICEN to one.

## 11.2 Subscriber Identification Module (SIM)

### 11.2.1 SIM Overview

The Subscriber Identification Module (SIM) is designed to facilitate communication to SIM cards or Eurochip pre-paid phone cards, and compatible with ISO/IEC 7816-3 standards. See the SIM block diagram in the figure below. The SIM module has one port that can be used to interface with the various cards. The interface with the Micro Controller Unit (MCU) is a 32-bit connection as described in the reference document IP Bus Specification.

Figure 11-31. SIM Block Diagram

#### 11.2.1.1 Features

The SIM design is summarized in the following sections:

- [SIM Bus Interface Overview](#)
- [SIM Clock Generator Overview](#)
- [SIM Transmitter Overview](#)

- [SIM Receiver Overview](#)
- [SIM Port Control Overview](#)
- [SIM General Purpose Counter Overview](#)
- [SIM LRC Block Overview](#)
- [SIM CRC Block Overview](#)

### 11.2.1.2 Modes of Operation

The SIM module I/O interface can be operated in one of three modes of operation summarized below.

- Two wire interface. In this mode both the IC pin RX and TX are used to interface to the SmartCard. This is activated by resetting the 3VOLT<sub>x</sub> bit in the port control register to a "0".
- External one wire interface. In this mode the IC pins RX and TX are tied together external to the IC and routed to the SmartCard. The 3VOLT bit in the port control register is reset to a "0" and the OD\_P<sub>x</sub> bit in the OD\_CONFIG register is set to a "1". For this interface to work properly the IC pin (RX-TX) must be pulled high by a resistor. The value should be selected small enough to give a fast enough rise time.
- Internal one wire interface. In this mode the IC pin TX is routed to the SmartCard. The receive pin RX is connected to the TX pin internal to the IC. The 3VOLT<sub>x</sub> bit in the port control register is reset to a "1" and the OD\_P<sub>x</sub> bit in the OD\_CONFIG register is set to a "1". For this interface to work properly the IC pin TX must be pulled high by a resistor. The value should be selected small enough to give a fast enough rise time.

#### NOTE

For the internal one wire interface to work, the bond pad must be capable of simultaneous input and output. (The input path should not be disabled when the output is enabled.)

### 11.2.1.3 SIM Bus Interface Overview

The SIM module is designed with a separate block that encompasses the interface to the IP bus. The bus interface is built in such a way as to be easily modified to other bus definitions. The SIM module is to be considered a 32-bit peripheral. To avoid endian issues with register access, all read/writes should be done as word access (32-bit). The bus interface has the following features:

- Peripheral Address/chip select decoding

- Illegal Address generation
- Dynamic wait state generation (tied inactive)
- Register organization
- Register bit implementations

See the table below for a summary of SIM top level interrupts.

**Table 11-47. SIM Top Level Interrupt Summary**

Flag	Interrupt Sources	Interrupt Masks	Description
SIMIRQ_N	XTE, OEF, SDI0, SDI1, TFO, GPCNT, BWT, BGT, CWT, RTE	XTM, OIM, SDIM0, SDIM1, TFOM, GPCNTM, BWTM, BGTM, CWTM, RTM	SIM General Interrupt
SIMDAT_N	TC, ETC, TFE, RDRF, TDTF, RFE	TCIM, ETCIM, TFEIM, RIM, TDTFM, RFEM	SIM Data Interrupt

### 11.2.1.4 SIM Clock Generator Overview

The SIM module contains a block designed specifically for generating the clocks used internal to the SIM module, and the clocks provided to the SIM cards. The clock generator has the following features:

- Programmable Divisor (CLK\_PRESCALER[7:0]) for SIM card clock generation (45-55% duty cycle except for divider by 3, 5, 7, 9)
- Receive clock generation (/1, /2, /4, /8, /16, /32, /31) from first stage
- Transmit clock generation (/12, /8) from second stage
- Programmable divisor for receive clock generation
- There are no interrupt sources generated by the SIM clock generator block

### 11.2.1.5 SIM Transmitter Overview

The SIM transmitter block contains the transmit state machine, transmit shift register, and transmit FIFO. The transmitter has the following features.

- 16 bytes deep transmit FIFO
- Automatic NACK generation on parity and overrun errors
- Hardware data format support (inverse convention or direct convention)
- Retransmission of data upon SIM card NACK request with programmable maximum threshold of retransmissions
- Programmable guard time between transmitted bytes
- Six interrupt sources (see the table below)

**Table 11-48. SIM Transmitter Interrupt Summary**

Flag	Flag Register	Mask	Mask Register	Description
TC	XMT_STATUS	TCIM	INT_MASK	Transmit Complete
ETC	XMT_STATUS	ETCIM	INT_MASK	Early Transmit Complete
TFE	XMT_STATUS	TFEIM	INT_MASK	Transmit FIFO Empty
XTE	XMT_STATUS	XTM	INT_MASK	Transmit Threshold Error
TFO	XMT_STATUS	TFOM	INT_MASK	Transmit FIFO Overfill Error
TDTF	XMT_STATUS	TDTFM	INT_MASK	Transmit Data Threshold Flag

### 11.2.1.6 SIM Receiver Overview

The SIM receiver block contains the receive state machine, receive FIFO, and control logic. The receiver has the following features.

- 288 bytes deep receive FIFO
- Decoding of initial character mode for setting data format
- Hardware data format support (inverse convention or direct convention)
- NACK detection
- Eleven ETU character support
- Character Wait Time Counter
- Six interrupt sources (see the table below)

**Table 11-49. SIM Receiver Interrupt Summary**

Flag	Flag register	Mask	Mask register	Description
BGT	RCV_STATUS	BGTM	INT_MASK	Block Guard Time flag
BWT	RCV_STATUS	BWTM	INT_MASK	Block Wait Time flag
RTE	RCV_STATUS	RTM	INT_MASK	Receive Nack threshold
CWT	RCV_STATUS	CWTM	INT_MASK	Character Wait Time flag
OEF	RCV_STATUS	OIM	INT_MASK	Overrun Error Flag
RDRF	RCV_STATUS	RIM	INT_MASK	Receive Data Register Full
RFE	RCV_STATUS	RFEM	INT_MASK	Receive Fifo Empty

### 11.2.1.7 SIM Port Control Overview

The SIM module supports numerous port control functions necessary for SIM card interaction. Each of the two SIM card ports has the following I/O: CLK,  $\overline{RST}$ , DATA\_RCV, DATA\_XMT, SIMPD (SIM presence detect), and SVEN (SIM  $V_{CC}$  enable). The following list gives a number of the important features of the port logic.

- Open-drain or push pull DATA\_XMT pin
- Port 1, port 0, ore alternate port selection
- SIM card presence detect with interrupt capability
- Sleep mode wake-up via SIM card presence detect interrupt
- Manual control of all SIM card interface signals
- Automatic power down of port logic on SIM card presence detect
- Two interrupt sources. See [Table 11-50](#).

**Table 11-50. SIM Card Detect Interrupts**

Flag	Flag register	Mask	Mask Register	Description
SDI1	PORT1_DETECT	SDIM1	PORT1_DETECT	SIM Detect Interrupt for port 1
SDI0	PORT0_DETECT	SDIM0	PORT0_DETECT	SIM Detect Interrupt for port 0

### 11.2.1.8 SIM General Purpose Counter Overview

The SIM module provides a 16-bit counter that can be configured to count using clock sources from the card clock, receive clock, or transmitter clock (ETU Clock). A programmable 16-bit register is provided to compare with the counter for interrupt generation:

- Selectable clock source
- 16-bit counter and comparator
- One Interrupt source (see the table below)

**Table 11-51. SIM General Purpose Counter Interrupts**

Flag	Flag Register	Mask	Mask Register	Description
GPCNT	XMT_STATUS	GPCNTM	INT_MASK	GPCNT Comparator Interrupt

### 11.2.1.9 SIM LRC Block Overview

The SIM module contains a block designed to generate Linear Redundancy Checking (LRC) information for both received and transmitted characters. The LRC block has the following features:

- 8-bit LRC value
- Valid LRC Detector
- There are no interrupt sources generated by the SIM LRC block

### 11.2.1.10 SIM CRC Block Overview

The SIM module contains a block designed to generate Cyclic Redundancy Checking (CRC) information for both received and transmitted characters. The CRC block has the following features:

- 16-bit CRC value
- 16-bit CRC Polynomial Generator
- Valid CRC Detector
- There are no interrupt sources generated by the >SIM CRC block

## 11.2.2 External Signal Description

### 11.2.2.1 External Signals Overview

See the table below for summary of the SIM module signals.

**Table 11-52. Signal Properties**

Name	Port	Function	Reset State	Pull-up
<b>External Signals</b>				
SIM_CLK	O	Clock for the smartcard on port0	0	Active
SIM_RST_B	O	Reset signal for port0	0	Active
SIM_SVEN	O	Vcc enable signal for port0	0	Active
SIM_TRXD	O	Transmit/receive data signal for port0	0	Active/Passive
SIM_PD	I	Card insertion detect signal for port0	-	-
sim_pin_sclk1	O	Clock for the smartcard on port1	0	Active
sim_pin_srst1	O	Reset signal for port1	0	Active
sim_pin_sven1	O	Vcc enable signal for port1	0	Active
sim_pin_data1_tx_out	O	Transmit/receive data signal for port1	0	Active/Passive
pin_sim_simpd1	I	Card insertion detect signal for port1	-	-
sim_rcvd1_io	I	I/O Receive data signal for port1	-	-
<b>Module Interrupts</b>				
ipi_int_sim_ipb_int	O	Active high SIM Interrupt. Composed of OEF, XTE, SDI1, and SDI0.	0	-
ipi_int_sim_data_irq	O	Active high SIM Data Interrupt. Composed of TC, ETC, TFE, and RDRF.	0	-
<b>Module DMA Requests</b>				
ipd_sim_tx_dmareq_b	O	Active low. Transmitter DMA request.	1	-
ipd_sim_rx_dmareq_b	O	Active low. Receiver DMA request.	1	-

## 11.2.2.2 Detailed Signal Descriptions

### 11.2.2.2.1 SIM\_CLK

The SIM\_CLK is an output from the chip to the SmartCard. This signal is the clock that the SIM module provides for the SmartCard. Typical frequencies are 1 MHz to 5 MHz. This clock is 372 times the data rate that is on pin SIM\_TRXD. There is no required timing relationship between this clock signal and any of the other data signals. This is because of the asynchronous nature of the protocol.

### 11.2.2.2.2 SIM\_RST\_B

The SIM\_RST\_B is the reset signal from the SIM to the SmartCard.

### 11.2.2.2.3 SIM\_SVEN

The SIM\_SVEN is the SmartCard power supply enable control signal.

### 11.2.2.2.4 SIM\_TRXD

The SIM\_TRXD is the data transmitted/received from the SIM module to the SmartCard. In a 1-wire mode of operating, this output port must be bidirectional with a pull-up resistor off chip.

### 11.2.2.2.5 SIM\_PD

The SIM\_PD is the SmartCard insertion detect.

## 11.2.3 SIM Functional Description

To best describe the organization of the SIM module from a user's point of view, it is instructive to view the SIM at a number of different levels of hierarchy. See [Figure 11-31](#) for illustration of the organization of SIM and connection of the signals to the available serial port.

The SIM module is essentially a standard UART with some special provisions made for SIM card communication. The SIM consists of the following main parts:

- IP bus interface
- Bus interface

- Clock generator
- Transmitter
- Receiver
- General purpose counter
- LRC blocks
- CRC blocks

See the figure below for an illustration of the block diagram in detail, specifically the main parts.

Figure 11-32. SIM Detailed Block Diagram

### 11.2.3.1 SIM Bus Interface

The IM Bus interface block has been designed to enable the SIM module to be easily ported to other MCU cores. The bus interface block contains all of the logic that uses the bus interface signals. See the figure below.

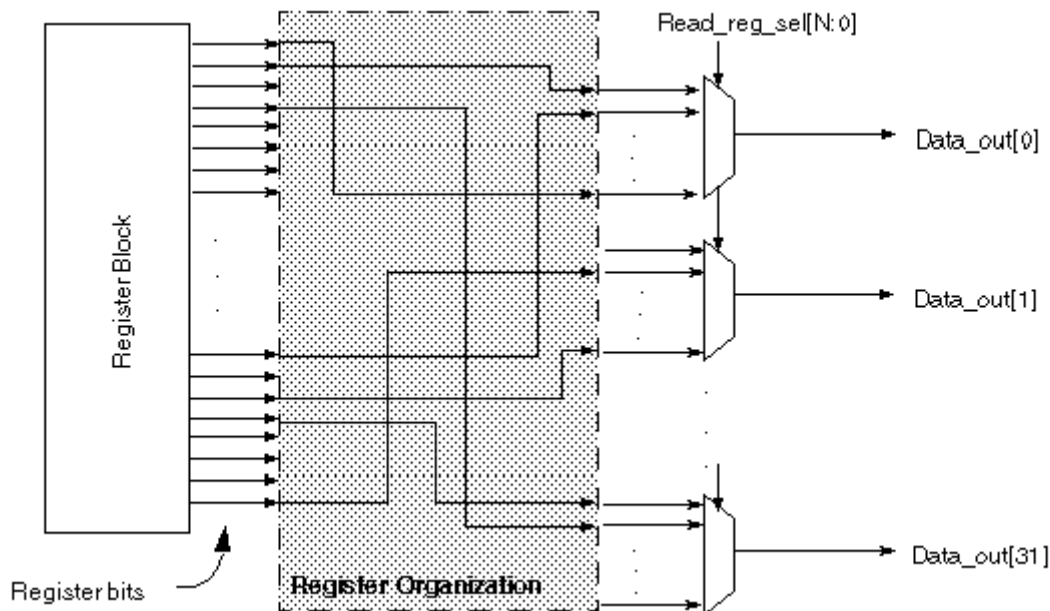

**Figure 11-33. SIM Bus Interface**

The bus interface block is responsible for peripheral bus address decoding, illegal access detection, dynamic wait-state requests, register organization, and register bit implementations. The address decoding uses the module address bus input along with the module select output of the IP bus to decode if the SIM module is being addressed. This decoding of these signals is done asynchronously. The output of the address decode is used with the read/write signals from the IP bus to determine the action requested by the bus master. If the read signal is active, the data\_out bus will be driven with the register

selected by the address decoding. If the write signal is active, the data\_in bus will be latched into the register selected by the address decoder at the rising edge of the data\_strobe signal.

The illegal access detection is implemented similarly to the address decoding. If the module\_select signal becomes active while the address inputs are pointing to an unimplemented address, the invalid signal is asserted asynchronously to the bus master. The invalid signal can also be generated under certain register access conditions such as writing to a full transmit FIFO, or writing to a read-only register. See the figure below.

**Figure 11-34. SIM Read Registers**

The register bit implementations are done inside the reg\_block sub-module. This block accepts the decoded read and write signals for the register bits generated in the address decoder. The data\_strobe output is used as the clock input to the register bits in order to clock in the new data during a write access. The write\_reg\_sel signals are used to gate the write action with the address decoding. The clearing mechanisms for status bits are implemented as write-one-to-clear. See the figure below.

Figure 11-35. Register Bit Diagram

In the "write-one-to-clear" register bit example, "set\_pulse" represents a pulsed signal generated in the data\_strobe clock domain to set the register output.

### 11.2.3.2 SIM Clocking

The SIM has three clock inputs:

- ipg\_clk-read/write clock; the frequency is half of platform\_clk
- ipg\_per\_clk-reference frequency input clock to generate the SIM card clock and other internal clocks; the frequency is platform\_clk divided by 8
- ckil-low frequency clock (32 KHz) used by the auto power down hardware circuit in the SIM. It is generated by dividing the platform\_clk by a division factor which is programmed in the SIMCLKCR register in the global utilities. The default value of the divider is 0x3D09, which gives a 32 KHz clock from a platform\_clk of 500 MHz.

Figure 11-36. SIM Clock Generator

Figure 11-37. SIM Clocking Diagram

### 11.2.3.3 SIM Clock Generator

The clock generator is responsible for implementing clock tree synthesis constructs, scan clock muxing, baud rate clock (BAUD\_CLK) generation, and providing clocks to the transmitter, receiver, and port controller sections of the SIM module. See the figure below for the schematic of the SIM clock generator. The dividers outlined in bold, generate a pulsed (gated) clock of the desired frequency. The pulse is equal in duration to one half the ipg\_per\_clk period. This clock is used internal to the SIM module to drive the transmit and receive sections of the module.

The dividers outline in normal, generate a clock of 45-55% duty cycle to drive the clock pin of the SmartCard. This clock is not used internal to the SIM module.

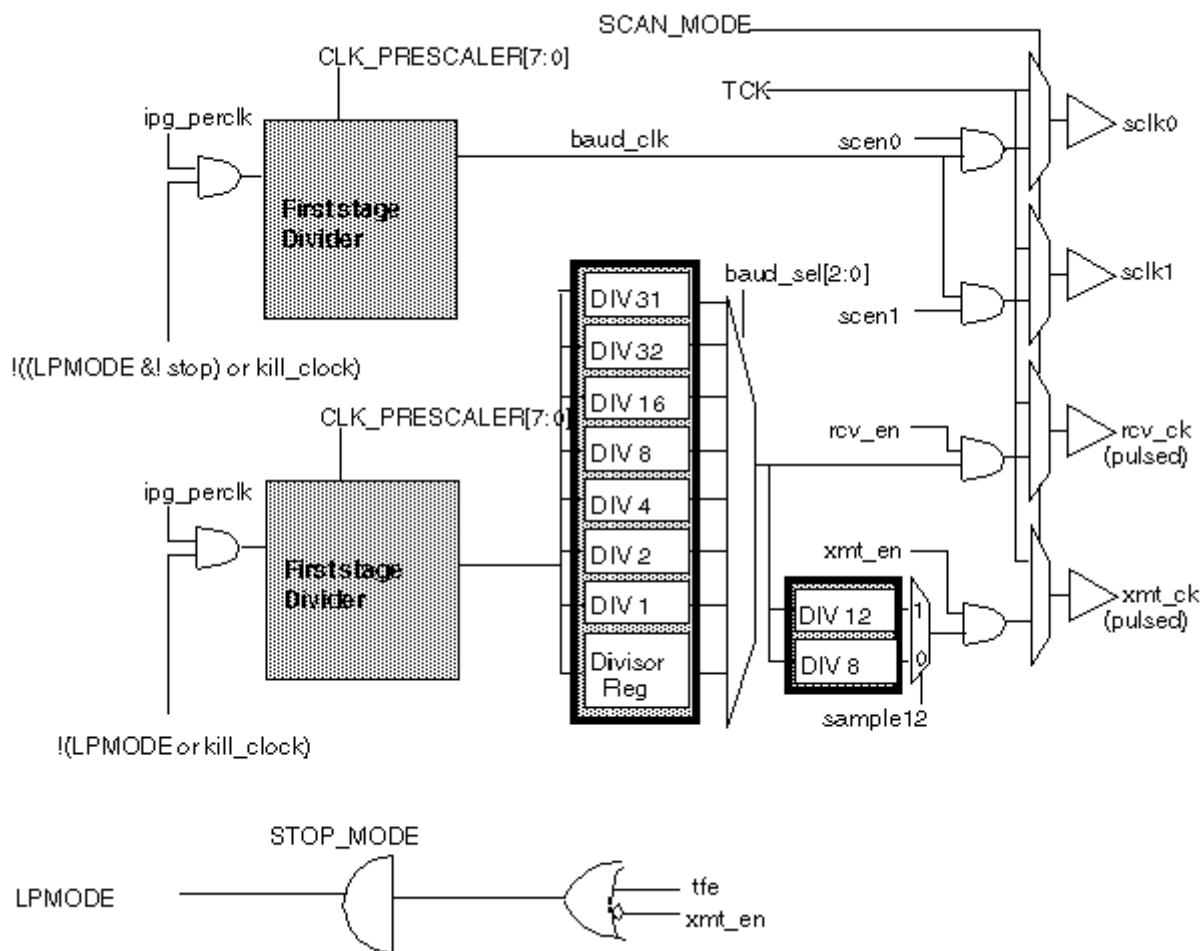

Figure 11-38. SIM Clock Generator

### 11.2.3.3.1 Scan Test

The scan clock muxing is implemented according to the design for testability rules.

### 11.2.3.3.2 Baud Clock Generation

The baud rate clock generation performed by the clock generator results in different frequencies. The default frequency is a divide by two of the ipg\_perclk input. The baud rate can be programmed to be ipg\_perclk divided by the even value using the CLK\_PRESCALER[7:0] bits as shown in the CLK\_PRESCALER register. The baud rate clock is generated in two forms in the design. The BAUD\_CLK that is used by the SIM cards (SCLK0) is generated so that it must be 45-55% duty at the divide values. This is necessary to meet the requirements of the ISO 7816 specification. The BAUD\_CLK that is used internal to the SIM module is generated as a gated version of the ipg\_perclk clock. The resultant clock will be a pulse of one-half ipg\_perclk period in width with the

expected frequency. The gated baud clock complies with the clock methodology initiative. The 50% duty cycle clock does not comply with the clock methodology initiative but this clock is not used as a clock internal to the SIM module. It is only used as a data path.

### 11.2.3.3.3 Transmitter Clock Generation

The transmitter clock (`xmt_clk`) is generated by the clock generator based on the values passed to it for the baud rate select (`baud_sel[2:0]`) and `sample12`. The transmit clock is gated by the transmit enable (`XMT_EN`) register bit. When the transmitter is enabled, the clock generator counts the appropriate number of receive clock (`rcv_clk`) positive edges to determine when to toggle the transmitter clock output. The transmitter clock is always based upon the receive clock.

### 11.2.3.3.4 Receiver Clock Generation

The receiver clock (`rcv_clk`) is generated by the clock generator based on the value passed to it for the baud rate select (`baud_sel[2:0]`). The receiver clock is gated by the receiver enable (`RCV_EN`) register bit. When the receiver is enabled, the clock generator counts the appropriate number of `BAUD_CLK` positive edges to determine when to toggle the receiver clock output. The number of `BAUD_CLK` positive edges is determined by the value of the baud rate select input (`baud_sel[2:0]`) and is programmable to these divisors: 31 (slowest because used with the 372/1 Fi/Di rate), 32, 16, 8, 4, 2, 1, and `divisor[7:0]`. The programmable divisor (`divisor[7:0]`) is programmable via the `DIVISOR_REG` register.

### 11.2.3.3.5 Port Control Clock Generation

The port controller clocks are provided by the clock generator for use on the SIM card ports. These clocks are equivalent in frequency to the `BAUD_CLK` and are gated by the SIM clock enable (`scen0`, `scen1`) signals. The level at which the card clocks (`SCLK0`, `SCLK1`) are stopped when disabled is determined by the SIM clock select polarity (`SCSP0`, `SCSP1`) inputs to the clock generator. Synchronizers are implemented to ensure glitch free operation of the card clocks when enabling/disabling, or changing the clock stopped polarity.

### 11.2.3.3.6 Low Power Mode Clock Control

The clock generator block is responsible for gating the clocks to the SIM module appropriately whenever a low power mode instruction is decoded. The IP interface provides two signals that encode the two available low-power states of the processor. These states are: `STOP` and `DOZE`. The response to the `DOZE` instruction is controlled

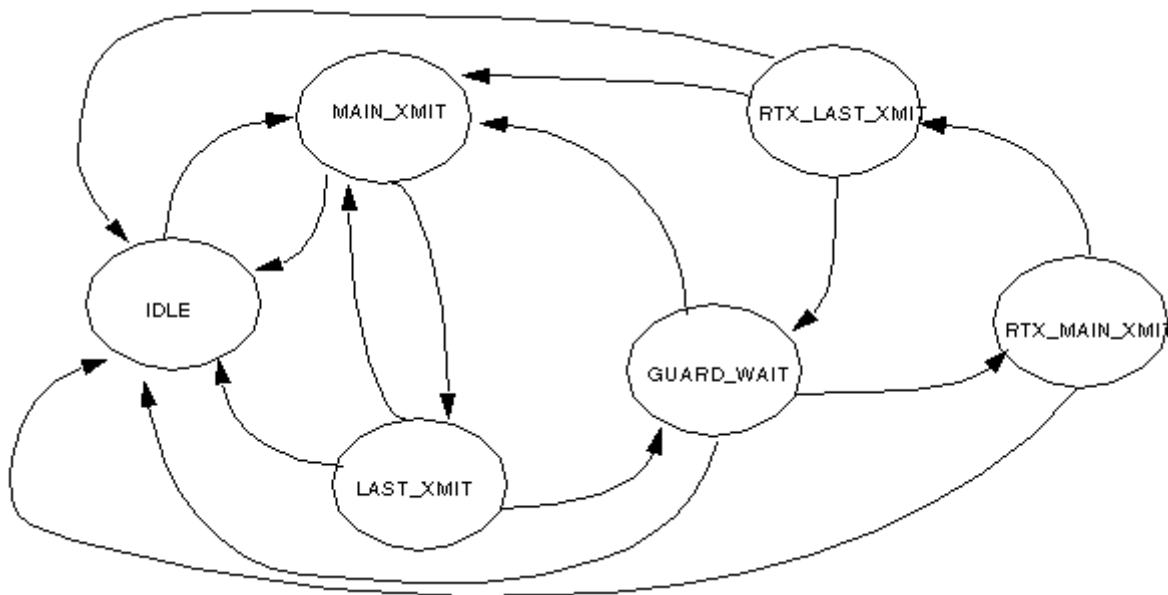

through the use of the DOZE bit in the RESET\_CNTL register. See the RESET\_CNTL register description. The response to the STOP instruction is controlled through the use of the STOP bit in the RESET\_CNTL register. See the RESET\_CNTL description

### 11.2.3.4 SIM Transmitter

The SIM Transmitter block has been designed to localize all transmit related circuitry into one section of hierarchy. The Transmitter block comprises the following sections of logic: transmit state machine, transmit shift register, transmit FIFO, guard time generator, transmit NACK control, and transmit data convention.

#### 11.2.3.4.1 Transmit State Machine

The Transmit state machine is the heart of the transmitter block. The state machine is responsible for sequencing through a transmit operation while reacting to inputs from the receiver, the transmit FIFO, and the guard time circuit. See the figure below for flow diagram of the transmit state machine.

**Figure 11-39. Transmit State Machine**

The functions performed by each state are:

- **IDLE**
  - This is the initial state. The state machine waits here until it detects XMT\_EN is set and a write to the transmit FIFO has occurred. The data pointed to by the transmit read pointer is loaded into the shift register, and the state machine

transitions to the MAIN\_XMIT state. Any time XMT\_EN is cleared, the state machine returns to this state.

- MAIN\_XMIT
  - The transmitter is operating normally in this state. The data in the shift register is shifting once every transmit clock cycle. When the second to last bit of the current transmission is about to be sent, the state machine transitions to the LAST\_XMIT state.
- LAST\_XMIT
  - This state transmits the last bit of the current transmission and determines the next operation. One of the following will occur.
    - If GETU[7:0] is non-zero, jump to the GUARD\_WAIT state.
    - If a transmit NACK error occurred, with a zero in GETU[7:0], jump to MAIN\_XMIT state to retransmit the current byte.
    - If no transmit NACK, and GETU[7:0] is zero, load the shift register, jump to MAIN\_XMIT to transmit the next byte
    - If no transmit NACK, GETU[7:0] is zero, and the FIFO is empty, jump to IDLE state; set the transmit complete (TC) flag.
- GUARD\_WAIT
  - The state machine remains in this state until the Guard time counter has expired.
    - If a transmit NACK error occurred on last transmission, jump to RTX\_MAIN\_XMIT and re-transmit
    - If no transmit NACK and the FIFO is not empty, load the shift register, jump to MAIN\_XMIT to transmit the next byte.
    - If no transmit NACK and the FIFO is empty, return to the IDLE state.
    - If transmit NACK threshold is detected, stop transmitter, set XTE flag, and jump to the IDLE state.
- RTX\_MAIN\_XMIT
  - The transmitter is operating normally in this state. The data in the shift register is shifting once every transmit clock cycle. When the second to last bit of the current transmission is about to be sent, the state machine transitions to the RTX\_LAST\_XMIT state. This state is identical to the MAIN\_XMIT state except that it retransmits the previously NACKed byte.
- RTX\_LAST\_XMIT
  - This state transmits the last bit of the current re-transmission and determines the next operation. One of the following will occur.
    - If GETU[7:0] is non-zero, jump to the GUARD\_WAIT state.
    - If a transmit NACK error occurred, with a zero in GETU[7:0], jump to GUARD\_WAIT state to check Transmit NACK threshold.

- If no transmit NACK, GETU[7:0] is zero, and the FIFO is not empty, load the shift register, jump to MAIN\_XMIT to transmit the next byte
- If no transmit NACK, GETU[7:0] is zero, and the FIFO is empty, jump to IDLE state; set the transmit complete (TC) flag.

#### 11.2.3.4.2 Transmit Shift Register

The transmit shift register is 11 bits wide and controlled by the transmit state machine described previously. The shift register shifts out data at the transmit clock frequency (xmt\_ck).

#### 11.2.3.4.3 Transmit FIFO

The transmit FIFO is implemented inside the transmitter block. The FIFO depth is 16 bytes. The FIFO block is shared by both SIM module ports. The transmit FIFO cannot be accessed by the alternate SIM module through the alternate port. Each write to the transmit FIFO increases the transmit FIFO write pointer. Each time the transmit shift register is loaded from the transmit FIFO, the transmit FIFO read pointer is increased. When the read and write pointers are equal, the transmit FIFO empty flag (TFE) is set. Software has no visibility of the transmit FIFO pointers, but a transmit FIFO threshold value can be set to alert the software when the number of bytes in the FIFO has reached a specified level. A read of the transmit FIFO register (XMT\_BUF) will return the last byte written to the FIFO. Writes to the transmit FIFO can occur at any time.

The transmit FIFO can be flushed by setting the XMT\_FLUSH bit in the RESET\_CNTL register. A transmit NACK threshold error (XTE) will halt the transmitter, and flush the transmit FIFO. The flush operation resets the transmit read and write pointers to equal values. Everything in the transmitter block is reset by the transmit flush operation. This does not include the control registers associated with the transmitter. The Transmit data threshold flag (TDTF) does not get cleared by the XMT\_FLUSH operation.

#### 11.2.3.4.4 Transmit Guard Time Generator

The guard time generator is simply a counter that is clocked by the transmit clock in order to delay the beginning of the next transmission and the setting of the transmit complete interrupt flag (TC) by a programmable amount of transmit bit widths (ETU's). The duration of the count is controlled by the GUARD\_CNTL register (GETU[7:0]). See the figure below for depiction of three transmit operations in order to show the effect of the guard time generator logic

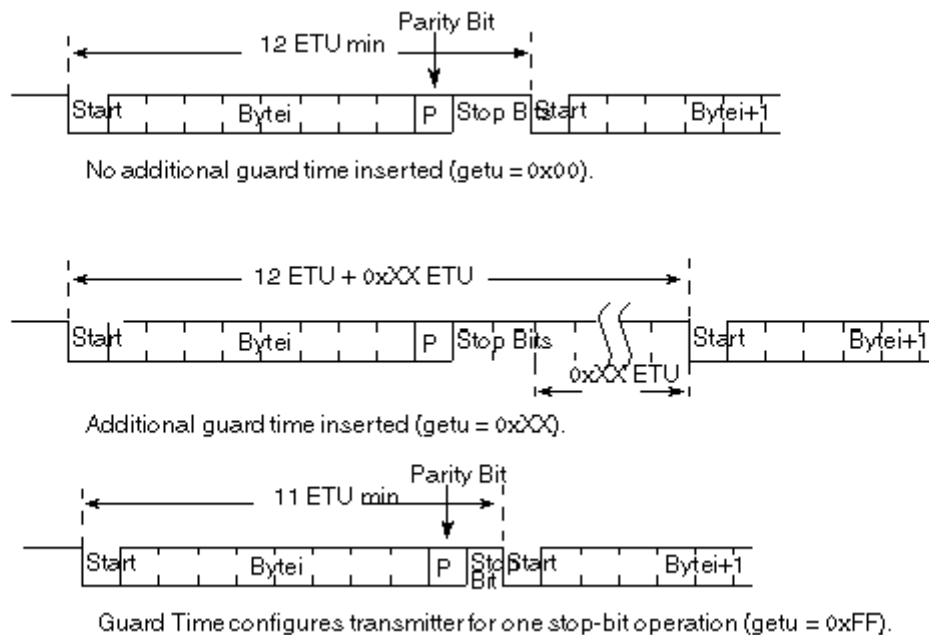

Figure 11-40. Transmit Guard Time

### 11.2.3.4.5 Transmit NACK Generator

The transmit NACK generator is responsible for driving the transmitter output low during the STOP bit time to signify an error was detected in the received data from the SIM card. This logic responds to a NACK request generated by the receiver block. The figure below shows a typical SIM transaction with the NACK pulse inserted.

Figure 11-41. Transmit NACK Generator

The transmit NACK generator is also responsible for keeping track of the number of NACKs received during a transmit operation. The SIM receive state machine detects NACKs generated by the SIM card, and reports them to the transmit NACK logic. Once the number of detected NACKs has reached the programmed threshold (XTH[3:0]), an interrupt flag is generated, the transmit FIFO is flushed, and the transmitter is disabled.

#### 11.2.3.4.6 Transmit Data Convention Logic

The transmit data convention logic provides the support for the two different data conventions available in SIM cards. See the figure below for an illustration of SIM data conventions.

Parity Bit: if configured for even parity, total number of logic ones in the 9 bits (8 bits data, 1 parity bit) will be even  
 if configured for odd parity, total number of logic ones in the 9 bits (8 bits data, 1 parity bit) will be odd  
 When configured for inverse convention, the parity bit is inverted by USIM before being transmitted.

Direct Convention: *ba* is lsb of data byte to be sent. *bh* is msb.  
 Neither the data bits nor parity bit is logically inverted.

Inverse Convention: *ba* is msb of data byte to be sent. *bh* is lsb.  
 Both the data bits and parity bit are logically inverted by hardware.

**Figure 11-42. SIM Data Conventions**

The direct data convention is the default. If the inverse convention bit (IC) in the DATA\_FORMAT register is set, then the transmit data convention logic will convert the output of the transmit FIFO to the inverse convention before sending it to the transmit shift register.

#### 11.2.3.5 SIM Receiver

The SIM Receiver block has been designed to localize all receive related circuitry into one section of hierarchy. The receiver block is comprised of the following functions: receive state machine and the receive FIFO.

### 11.2.3.5.1 Receive State Machine

The receive state machine is responsible for sampling the receive data pin and capturing the bit value into the receive shift register. Additionally, the receive state machine can detect the START bit, parity errors, framing errors, and initial character when operating in initial character mode.

Once enabled by the RCV\_EN bit in the ENABLE register, the receive state machine sequences through the states as shown in the figure below.

**Figure 11-43. Receive State Machine**

The states identified with a "8x" are used when operating in a 8x oversampling mode. The states identified with a "12x" are used when operating in a 12x oversampling mode. This mode is only used when sample12 is set to "1". The number following the oversampling mode identifier represents the state number in the current mode. There are 12 states in "12x" mode, and 8 states in "8x" mode. Some states simply implement a one RCV\_CK delay. States that perform additional functions are:

- RCV8x\_1, RCV12x\_1

- This is the initial state of the receive state machine. If the first bit has not been received, the state machine remains in this state until a valid START bit is detected. For every subsequent bit, this state is simply a one RCV\_CK cycle delay.
- RCV8x\_2, RCV12x\_2
  - This state captures the first sample of the current receive data input.
- RCV12x\_3
  - This state captures the second sample of the current receive data input.
- RCV12x\_4
  - This state captures the third sample of the current receive data input.
- RCV8x\_3, RCV12x\_5
  - This state checks if we are receiving a correct START Bit. If not, Then we return to state 1.
- RCV8x\_4, RCV12x\_6
  - If we are in the 11th Bit, We check for Parity or Initial Character errors and send NACK if needed.
- RCV8x\_5, RCV12x\_7
  - Store current Bit value in Shift Register. If this is the first bit and the value is not 0, restart the State Machine.
- RCV8x\_6, RCV12x\_8
  - If the current bit is the last bit of the transfer, Set flag to transfer Shift Register to Receive Buffer.
- RCV8x\_7, RCV12x\_9
  - Clear flag for transferring Shift Register to Receive Buffer.
- RCV12x\_10
  - If the current bit is the last bit of the transfer (first stop bit), this state takes the sample of the NACK window.
- RCV12x\_11
  - If the current bit is the last bit of the transfer (first stop bit), this state takes the sample of the NACK window.
- RCV8x\_8, RCV12x\_12
  - This state represents the end of the current receive input bit. Several operations occur during this state, including:
    - Increment bit counter
    - Perform a majority vote on the NACK samples and notify the transmitter if a NACK pulse was detected.

### 11.2.3.5.2 Data Sampling / Voting

The receive state machine runs at the receive clock rate (RCV\_CK). This clock is used to oversample the received data at either a 8X or 12X sample rate. For each input bit, the receive state machine captures 3 samples. A majority voting algorithm is then applied to determine the value of the bit received. The value common to 2 or more of the samples is determined to be the bit value in the receive shift register.

### 11.2.3.5.3 Start Bit Detection

The SIM receive input is defined to be high when not active. The data transmission is defined to begin with a low pulse for a bit duration. This is called the START bit. The receive state machine is responsible for detecting and validating the START bit. The receive state machine samples the START bit three times using a majority voting scheme to determine if the START bit is valid. This will effectively filter out any low receive inputs shorter than one RCV\_CK period. See the figure below for an illustration of a typical SIM data transaction with the START bit identified.

Figure 11-44. Start Bit Diagram

### 11.2.3.5.4 Parity Error Detection

The receive state machine is responsible for detecting parity errors in the received data. Data is always transmitted with even parity, except when in inverse convention mode. In inverse convention mode, all data bits and the parity bit are complemented making the data appear to be odd parity. The parity bit is defined as the 10th bit of the received data. The parity of the 2nd through 10th received bits is calculated by the receiver parity logic. This logic determines if the parity of the 9 received bits is correct. See the figure below for an illustration of a typical SIM data transaction with the parity bit identified.

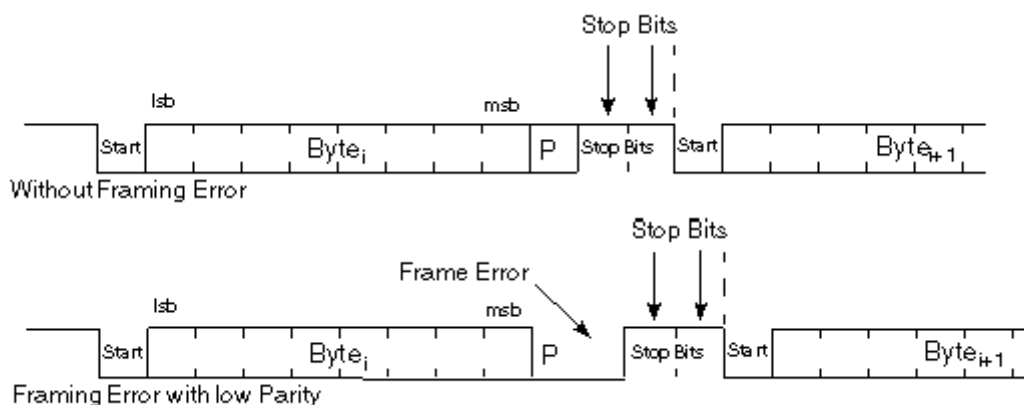

**Figure 11-45. Parity Bit Diagram**

When a parity error is detected on a given byte, the RCV\_PF bit for that byte is set in the receive FIFO if NACK generation on errors is disabled (ANACK = 0 in the CNTL register). A parity error cannot cause an interrupt, but when NACK generation is enabled (ANACK = 1), it can signal the SIM transmitter to create a NACK pulse to the SIM card asking for a retransmission of the corrupted data.

### 11.2.3.5.5 Framing Error Detection

The receive state machine is responsible for detecting framing errors in the received data. A SIM data transaction is defined as 11 or 12 bits long consisting of the START bit, 8 data bits, 1 parity bit and 1 or 2 STOP bits. A framing error occurs when the STOP bit is not detected during the 11th bit time of a data transaction. The STOP bit is generally defined as two bit times (ETU's) of a high pulse following the parity bit. When the GUARD\_CNTL register is programmed to 0xFF, the STOP bit is defined as one bit time. A framing error can only occur when the parity bit of the current byte is low, and the STOP bit arrives late. See the figure below for an illustration of a typical SIM data transaction with the STOP bits identified. Also, shown is a SIM data transaction with a late arriving STOP bit indicating a framing error.

**Figure 11-46. Framing Error Diagram**

When a framing error is detected on a given byte, the RCV\_FE bit for that byte is set in the receive FIFO. A framing error cannot cause an interrupt, nor can it create a NACK pulse to the SIM card asking for a retransmission of the corrupted data.

### 11.2.3.5.6 NACK Detection

The existence of the NACK pulse is sampled by the receive state machine at 11 Elementary Time Units (ETUs) after the falling edge of the START bit. An ETU is equivalent in time to 1 transmit clock period. Once the receiver detects a NACK, it signals the transmitter that an error occurred. The transmitter will not initiate retransmission for at least another two ETU times as required by the ISO 7816 specification.

### 11.2.3.5.7 Initial Character Detection

The SIM receive state machine supports the detection of special characters that allow it to determine what data format is being used by the connected SIM card. When placed in initial character mode, the SIM expects to receive one of two potential characters that it will use to set the data format control bit, IC, in the DATA\_FORMAT register.

The two possible data formats are inverse convention and direct convention. The following figures illustrate the differences between the two formats. Essentially, inverse convention differs from direct convention in that the order of the data is flipped msb for lsb and the data bits and parity bit are logically inverted. When receiving inverse convention data, the transformation of the data back to direct convention format is done in hardware, including the inversion of the data and parity bits.

**Figure 11-47. Valid Initial Characters**

Parity Bit: if configured for even parity, total number of logic ones in the 9 bits (8 bits data, 1 parity bit) will be even  
 if configured for odd parity, total number of logic ones in the 9 bits (8 bits data, 1 parity bit) will be odd  
 When configured for inverse convention, the parity bit is inverted by SIM card before being transmitted.

Direct Convention: *ba* is lsb of data byte to be sent. *bh* is msb.  
 Neither the data bits nor parity bit is logically inverted.

Inverse Convention: *ba* is msb of data byte to be sent. *bh* is lsb.  
 Both the data bits and parity bit are logically inverted by SIM card.

**Figure 11-48. Inverse Convention versus Direct Convention**

### 11.2.3.5.8 Receive FIFO

The receive FIFO is implemented inside a sub-block of the receiver block. The FIFO depth is 288 bytes. The FIFO block is shared by both SIM module ports. The receive FIFO cannot be accessed by another SIM module through the alternate port. Only the port1 IO pins can be accessed through the alternate port. The secondary SIM would then uses its own internal FIFO while using the primary SIM IO ports. This is only done if it is required to control two SIM cards at the same time. If the two SIM card access only occurs one at a time, then a single SIM module can control both SIM cards (one on port0 and one on port1). The receive FIFO is accessed through the RCV\_BUF register.

The receive FIFO is loaded from the receive shift register after the final bit of the current SIM card transmission has been received. The FIFO contains 10 bits per transmission. The lower eight bits contain the received data byte. Bits 8 and 9 contain the parity and framing status for the received byte.

Each read from the receive FIFO increases the receive FIFO read pointer. Each time the receive shift register is transferred to the receive FIFO, the receive FIFO write pointer is increased. When the difference between the read and write pointers equals the programmed threshold value (RDT), the receive data register full flag (RDRF) will be set. An interrupt can be generated by the RDRF flag if the RIM bit in the INT\_MASK register is cleared. Software has no visibility of the receive FIFO pointers. A write to the receive FIFO register (RCV\_BUF) will generate an invalid access exception to the processor.

The receive FIFO can be flushed by setting the RCV\_FLUSH bit in the RESET\_CNTL register. The flush operation resets the receive read and write pointers to equal values. All logic associated with the receiver will be reset by the flush operation except for receiver control registers.

### 11.2.3.5.9 Overrun Detection

The receive FIFO logic is responsible for detecting an overrun condition. When a received byte is transferred from the receive shift register to a receive FIFO that contains 288 unread bytes, the SIM receiver will flag an overrun condition. This condition will always set the overrun error flag, OEF in the RCV\_STATUS register. The received byte will be discarded leaving the 288 unread bytes in the FIFO unaltered. The SIM module will generate a NACK to the SIM card on an overrun condition if the ONACK bit in the CNTL register is set. The SIM module will continually NACK SIM card transmissions until a read of the receive FIFO occurs.

### 11.2.3.5.10 Character Wait Time Counter

The SIM receiver block includes a 16-bit counter that counts the number of bit times (ETUs) between received characters. When enabled, the Character Wait Time Counter (CWT) will not start counting until after the START bit(s) of a valid character has been received. The counter is synchronized to the receive character bit positions so that an accurate count of the number of ETUs between characters can be made. The Character Wait Time Counter has a 16-bit programmable comparator. Software can write the expected number of ETUs between characters to the comparator. If the time between characters exceeds this value, an interrupt flag will be set and an interrupt generated if the mask is clear.

## 11.2.3.6 SIM Port Control

The SIM Port Control block has been designed to localize all port related circuitry into one section of hierarchy. The port control block comprises the following functions: SIM card interface, SIM Card presence detect, and SIM card auto-power down.

### 11.2.3.6.1 SIM Card Interface

The SIM module allows for direct control of two separate SIM cards. The SIM module does not support simultaneous communication with two SIM cards. To achieve simultaneous communication with two SIM cards, a second SIM module must be used. The SIM module can relinquish control of the inactive port to a secondary SIM module by setting the AMODE bit in the SETUP register. When alternate SIM Card Mode enable, output signals in port1 is directly from the secondary SIM module and input signals in port1 will pass through to the secondary SIM module.

The SIM card clock is generated in the SIM clock generator. The SIM card reset is controlled by software through the PORT0\_CNTL register. Since the SIM module does not support a separate transmit data and receive data port, the 3VOLT0 bit should be set to 1.

#### 11.2.3.6.2 SIM Card Presence Detect

The SIMPD<sub>x</sub> input allows for detection of the insertion or removal of a SIM card. The SPDS<sub>x</sub> control bit in the PORT<sub>x</sub>\_DETECT register allows the software to configure which edge of the SIMPD<sub>x</sub> pin will cause a presence detect event. A maskable interrupt can be generated when a SIMPD<sub>x</sub> event occurs.

An internal pull-down device is present on the SIMPD<sub>x</sub> pins. This will provide for a high to low transition on the SIMPD<sub>x</sub> pin when a SIM card is removed.

#### 11.2.3.6.3 SIM Card Automatic Power Down

When interfacing to the SIM cards, it is necessary to follow a particular sequence when powering them up and down. The SIM port control block contains hardware that provides the correct sequence to power down a SIM card (see the figure below). The power up sequence must be done manually by the software using the pin control bits supplied in the PORT<sub>x</sub>\_CNTL registers.

The power down sequence is specified in ISO 7816 as:

1. RST transitions from high to low
2. CLK is turned off to a low
3. I/O transitions from high impedance to low
4. SIM V<sub>CC</sub> is turned off

**Figure 11-49. Auto Power Down Sequence**

### 11.2.3.7 SIM General Purpose Counter

The SIM module provides a 16-bit counter for use when timing events during SIM card communication. The clock source for the counter is selectable between three sources: BAUD\_CLK, RCV\_CLK, or XMT\_CK (ETU clock). The GPCNT\_CLKSEL[1:0] bits in the CNTL register are used to select the clock input. The counter is enabled as soon as the input clock is selected. The starting of the counter is immediate once the input clock is running. Software can control the three input clock sources by using the KILL\_CLOCK, RCV\_EN and XMT\_EN bits provided in the RESET\_CNTL and ENABLE registers.

To run the counter from the card clock source the following conditions must be met:

1. 'KILL\_CLOCK = 0' in the RESET\_CNTL register.
2. 'GPCNT\_CLKSET[1:0] = 01' in the CNTL register

The counter will begin to count at the card clock rate as soon as these conditions are met.

To run the counter from the receive clock source the following conditions must be met:

1. 'KILL\_CLOCK = 0' in the RESET\_CNTL register.
2. 'RCV\_EN = 1' or XMT\_EN = 1 in the ENABLE register
3. 'GPCNT\_CLKSET[1:0] = 10' in the CNTL register

The counter will begin to count at the receive clock rate as soon as these conditions are met.

To run the counter from the ETU (transmit) clock source the following conditions must be met:

1. 'KILL\_CLOCK = 0' in the RESET\_CNTL register.
2. Either one of the following:
3. "RCV\_EN = 1' in the ENABLE register and 'CWT\_EN = 1' in the CNTL register  
'XMT\_EN = 1' in the ENABLE register
4. 'GPCNT\_CLKSET[1:0] = 11' in the CNTL register

The counter will begin to count at the ETU clock rate as soon as these conditions are met.

The counter can be reset by setting GPCNT\_CLKSEL[1:0] to 00. A 16-bit comparator value is provided that allows the software to select a count value at which an interrupt flag can be set and an interrupt generated if the mask is clear.

### 11.2.3.8 SIM LRC Block

The SIM module provides an 8-bit Linear Redundancy Check (LRC) generator / checker. The block is provided for use with T=1 SIM cards that support LRC. This block can be enabled through the LRCEN bit in the CNTL register. This block performs an 8-bit exclusive-OR on all received or transmitted characters. At the end of the reception of a block of characters, the result is expected to be 00. If so, the LRCOK bit is set in the RCV\_STAT register. During transmission, the LRC block Exclusive-ORs each character that is transmitted with the current value of the LRC. If the XMT\_CRC\_LRC bit in the CNTL register is set, the LRC value will automatically be sent by the SIM transmitter as the final character when the transmit FIFO empties.

The LRC value can be reset in multiple ways. Clearing the LCREN bit in the CNTL register will reset the LRC value. At the end of a transmission (either after the LRC byte is transmitted, or after the last character in the transmit FIFO is sent when XMT\_CRC\_LRC is clear), the LRC value is automatically reset by the SIM hardware. Finally, when setting the XMT\_EN bit, the SIM hardware resets the LRC value.

### 11.2.3.9 SIM CRC Block

The SIM module provides an 16-bit Cyclic Redundancy Check (CRC) generator / checker. The block is provided for use with T=1 SIM cards that support CRC. This block can be enabled through the CRCEN bit in the CNTL register. This block performs a polynomial based check on all received or transmitted characters. The polynomial description is shown in Figure 4-17. The polynomial used is the standard CRC-CCITT

where  $g(x) = x^{16} + x^{12} + x^5 + 1$ . The CRC register is initialized to all "1" before the data is shifted in. Before transmission the resulting CRC is inverted. For example, transmitting a 0xFA results in the following:

- Data = 0x5F (bit reversal of 0xFA)
- crc = 0x4AEA
- invert the crc = 0xB515 (bit reversal of 0xADA8)
- data transmitted = 0xFA, 0xAD, 0xA8

See the figure below for an illustration of the SIM CRC block.

Figure 11-50. CRC Block Diagram

At the end of the reception of a block of characters, the residual from the CRC calculation is compared to 0x1D0F. If so, the CRCOK bit is set in the RCV\_STAT register. During transmission, the CRC block updates the current value of the CRC residual using each character. If the XMT\_CRC\_LRC bit in the CNTL register is set, the CRC value will automatically be inverted and sent by the SIM transmitter as the final two characters when the transmit FIFO empties.

The CRC value can be reset in multiple ways. Clearing the CRCEN bit in the CNTL register will reset the CRC value. At the end of a transmission (either after the CRC characters are transmitted, or after the last character in the transmit FIFO is sent when XMT\_CRC\_LRC is clear), the CRC value is automatically reset by the SIM hardware. Finally, when setting the XMT\_EN bit, the SIM hardware resets the CRC value.

### 11.2.3.10 Module Interrupts

See the table below for the list of all possible interrupt sources and their corresponding mask bits. All SIM interrupts are logically ORed to create the active low irq\_n and data\_irq\_n signals that go to the ITC module. All mask bits are such that a logic 1 implies that the corresponding interrupt is disabled (masked), whereas a 0 implies that the interrupt enabled (unmasked). All of these mask bits are logic 1 out of reset (all interrupts are masked).

**Table 11-53. SIM Module Interrupts**

Flag	Flag Register	Mask	Mask Register	Description
TC	XMT_STATUS	TCIM	INT_MASK	Transmit Complete
ETC	XMT_STATUS	ETCIM	INT_MASK	Early Transmit Complete
TFE	XMT_STATUS)	TFEIM	INT_MASK	Transmit FIFO Empty
XTE	XMT_STATUS	XTM	INT_MASK	Transmit Threshold Error
TFO	XMT_STATUS	TFOM	INT_MASK	Transmit FIFO Overfill error
TDTF	XMT_STATUS	TDTFM	INT_MASK	Transmit Data Threshold Flag
GPCNT	XMT_STATUS	GPCNTM	INT_MASK	General Purpose Counter Comparator Flag
RDRF	RCV_STATUS	RIM	INT_MASK	Receive data register full (FIFO threshold level reached)
OEF	RCV_STATUS	OIM	INT_MASK	Overrun Error Flag
CWT	RCV_STATUS	CWTM	INT_MASK	Character Wait Time Counter Comparator Flag
BWT	RCV_STATUS	BWTM	INT_MASK	Block Wait Time Counter Comparator Flag
BGT	RCV_STATUS	BGTM	INT_MASK	Block Guard Time Counter Comparator Flag
RTE	RCV_STATUS	RTM	INT_MASK	Receive NACK Threshold Error
SDI1	PORT1_DETECT	SDIM1	PORT1_DETECT	SIM Detect Interrupt for port 1
SDI0	PORT0_DETECT	SDIM0	PORT0_DETECT)	SIM Detect Interrupt for port 0

## 11.2.4 Initialization/Application Information

This section describes the intended programming model for using the SIM module. The section describes how to begin a typical mode of operation using the registers.

### 11.2.4.1 Configuring SIM for Operation

The following is a list of items that need to be performed in order to configure the SIM module for operation:

1. Port selection in the SETUP register.
  - a. Select which SIM module port is active by writing the SPS bit.
  - b. Select whether the second SIM module port is active at the same time under the control of an alternate SIM module by writing the AMODE bit.
2. Enable the selected port (for port 1, see PORT1\_CNTL register; for port 0, see PORT0\_CNTL) following the SIM power up procedure specified in ISO 7816.
  - a. Program 3VOLT0 pin of PORT0\_CNTRL register to 1.
  - b. Enable power to the SIM card using the SVEN1 or SVEN0 bit.
  - c. Enable SIM module transmit data output using the STEN1 or STEN0 bit. This is required to allow the SIM receiver to create NACK pulses.
  - d. Enable SIM card clock using the SCEN1 or SCEN0 bit.
  - e. Release the SIM card reset using the SRST1 or SRST0 bit (assert SRSTx high).
3. Select XMT port driver type (open-drain or push-pull) in the OD\_CONFIG register.
  - a. Configure the selected port to be open drain or push-pull by using the OD\_P1 or OD\_P0 bit.
4. Choose the port baud rate in the CNTL register.
  - a. Select the SIM card clock rate by using the CLK\_PRESCALER[7:0] register.
  - b. Select the SIM card baud rate by using the BAUD\_SEL[2:0] bits and SAMPLE12.

#### NOTE

Follow the ISO 7816 spec with regards to card clock frequencies to ensure the maximum frequency specification is not violated.

5. Select Data format type, or place SIM receiver in initial character mode.
  - a. Select inverse convention or direct convention by using the IC bit in the DATA\_FORMAT register, or
  - b. Enable initial character mode by using the ICM bit in the CNTL register.

### 11.2.4.1.1 Configuring SIM Receiver

The following is a list of items that need to be performed in order to configure the SIM receiver for operation:

1. Enable NACK capability in CNTL register.
  - a. Select NACK generation on parity errors, or invalid initial character by using the ANACK bit.
  - b. Select NACK generation on overrun conditions by using the ONACK bit.
2. Select the desired Receive NACK threshold and receive FIFO threshold in RCV\_THRESHOLD register.
  - a. Program the threshold at which the RDRF flag will be set by using the RDT bits.
  - b. Program the threshold at which the RTE flag will be set by writing to the RTH[3:0] bits. If an auto power down after RTE flag is set, is desired, then enable the SIM card auto power down by setting the SAPD0,1 bits in the port0,1\_cntl register.
3. Configure the Character Wait Time Counter, the Block Wait Timer Counter and the Block Guard Time Counter.
4. Enable interrupts in the INT\_MASK register.
  - a. Enable the receive data register full interrupt by using the RIM bit
  - b. Enable the receive threshold error interrupt by using the RTM bit.
  - c. Enable the overrun condition interrupt by using the OIM bit.
  - d. Enable the Character Wait Time interrupt by using the CWTM bit
5. Enable enforce reception early stop function in ENABLE register.
  - a. Enable the enforce reception early stop enable by using the ESTOP\_EN bit.
  - b. Enable the enforce reception early stop execution by using the ESTOP\_EXE bit.

### 11.2.4.1.2 Configuring SIM Transmitter

The following is a list of items that need to be performed to configure the SIM transmitter for operation:

1. Select desired re-transmission threshold for NACKed characters in XMT\_THRESHOLD register.
  - a. Program the threshold at which the XTE flag will be set by using the XTH[3:0] bits.
2. Select the guard time between transmissions in the GUARD\_CNTL register.
  - a. Program the desired guard time between characters transmitted by the SIM module by using the GETU[7:0] bits.
3. Select the desired Transmit FIFO threshold level in the XMT\_THRESHOLD register.
  - a. Program the desired threshold using the TDT[3:0] bits.
4. Enable interrupts in the INT\_MASK register.

- a. Enable the transmit complete interrupt by using the TCIM BIT.
  - b. Enable the early transmit complete interrupt by using the ETCIM bit.
  - c. Enable the transmit FIFO empty interrupt by using the TFEIM bit.
  - d. Enable the transmit threshold error interrupt by using the XTM bit.
  - e. Enable the transmit FIFO threshold interrupt by using the TDTFM bit.
  - f. Enable the transmit FIFO overflow interrupt by using the TFOM bit.
5. Enable NACK delay detection in ENABLE register.
    - a. Enable the NACK delay detection enable by using the NACK\_DD\_EN bit.

### 11.2.4.1.3 Configuring SIM General Purpose Counter

The following is a list of items that need to be performed in order to configure the SIM General Purpose Counter for operation:

1. Select desired clock source for the General Purpose Counter using the CNTL register.
  - a. Use the GPCNT\_CLKSEL[1:0] bits to select the desired clock source for the counter
2. Program counter comparator using the GPCNT register.
  - a. Use the GPCNT[15:0] bits to select the desired count value at which the GPCNT interrupt flag will be set.
3. Enable the selected clock source for the General Purpose Counter using either the RESET\_CNTL or ENABLE registers.
  - a. If the GP Counter is configured for the card clock, enable the clock by clearing the KILL\_CLOCK bit in the RESET\_CNTL register.
  - b. If the GP Counter is configured for the receive oversample clock, enable this clock by setting the RCV\_EN bit or XMT\_EN bit in the ENABLE register.
  - c. If the GP Counter is configured for the transmit oversample clock, enable this clock by setting the XMT\_EN bit in the ENABLE register.
4. Enable interrupts in the INT\_MASK register.
  - a. Enable the general purpose counter interrupt by using the GPCNTM bit.

### 11.2.4.1.4 Configuring SIM to Measure WWT (Work Wait Time) for Type=0 Smartcards

The following is a list of items that need to be performed in order to configure the SIM to measure work wait time. This is intended for type=0 SmartCards. Work wait time is a combination of BWT and CWT. The CWT timer is to measure the time between the start bits of two consecutive characters in the block received from the SmartCard. If this time is larger than the value programmed in the cwt[15:0] register, then a flag will be set and an interrupt generated. This timer can be used for both type=0 and type=1 SmartCards. The BWT and BGT timer are used to measure the delay between the leading edge of the

last character of the block received by the card and the leading edge of the first character of the next block sent by the card. If you want the SIM to enforce a WWT of 100 bits. Then, you must activate both the CWT and BWT, and program both of them for a value of 100 bits. When measuring WWT, the BGT timer will not be used so it will be masked (inactive) by the BGTM bit. Below is the sequence to program the SIM to send and receive data while checking WWT.

1. Program both the CWT and the BWT (low and high) registers to the WWT (work wait time) value that needs to be enforced. Set BGT register to 0 (this is the default value).
2. Activate both the CWT and BWT functions by setting the CWTEN and BWTEN bit in the CNTL register.
3. Enable the CWT and BWT interrupts by clearing the CWTM and BWTM bits in the INT\_MASK register.
4. Program the data to send to the SmartCard by writing data to XMT\_BUFFER
5. Activate the SIM transmit and receive by setting bits XMT\_EN and RCV\_EN in the ENABLE register.
6. If the software has more data to send, then as the FIFO starts to get near empty, it should write more data to the XMT\_BUFFER. If the software does not have any more data to send then proceed to the next step.
7. When SmartCard has completed its transmission to the SIM module, disable the BWT by clearing the bit BWTEN in the CNTL register. This will prepare SIM to measure the next block wait time.
8. Disable the SIM transmitter by clearing the XMT\_EN bit in the ENABLE register.
9. Program the next data to send by writing data to the XMT\_BUFFER.
10. Enable the BWT function by setting the BWTEN bit in the CNTL register.
11. Enable the SIM transmitter by setting the XMT\_EN bit in the ENABLE register.
12. Steps 6 to 10 can be repeated for each transmission to the SmartCard.
13. If a CWT or a BWT interrupt occurs, then the software should consider that a WWT violation. The software should clear the CWT or BWT interrupt by writing a "1" to the BWT or CWT bit in the RCV\_STATUS register.

#### 11.2.4.1.5 Configuring SIM to measure CWT, BWT, BGT for type=1 SmartCards

The following is a list of items that need to be performed in order to configure the SIM to measure CWT, BWT, BGT. This is intended for type=1 SmartCards. The CWT timer is to measure the time between start bits in the consecutive characters received from the SmartCard. If this time is larger than the value programmed in the CWT[15:0] register, then a flag will be set and an interrupt generated. This timer can be used for both type=0 and type=1 SmartCards. The BWT, BGT timer is used to measure the delay between the leading edge of the last character of the block received by the card and the leading edge

of the first character of the next block sent by the card. If this time is larger than the value in the both BWT registers (BWT and BWT\_H), then the BWT flag will be set and an interrupt generated. If the time is less than the value in the BGT register, then the BGT flag will be set and an interrupt generated.

1. Program the CWT, BWT, BWT\_H and BGT registers to the value that needs to be enforced.
2. Activate both the CWT and BWT functions by setting the CWTEN and BWTEN bit in the CNTL register.
3. Enable the CWT, BWT, BGT interrupts by clearing the CWTM, BWTM, BGTM bits in the INT\_MASK register.
4. Program the data to send to the SmartCard by writing data to XMT\_BUFFER
5. Activate the SIM transmit and receive by setting bits XMT\_EN and RCV\_EN in the ENABLE register.
6. If the software has more data to send, then as the FIFO starts to get near empty, it should write more data to the XMT\_BUFFER. If the software does not have any more data to send then proceed to the next step.
7. When SmartCard has completed its transmission to the SIM module, disable the BWT by clearing the bit BWTEN in the CNTL register. This will prepare SIM to measure the next block wait time.
8. Disable the SIM transmitter by clearing the XMT\_EN bit in the ENABLE register.
9. Program the next data to send by writing data to the XMT\_BUFFER.
10. Enable the BWT function by setting the BWTEN bit in the CNTL register.
11. Enable the SIM transmitter by setting the XMT\_EN bit in the ENABLE register.
12. Steps 6 to 10 can be repeated for each transmission to the SmartCard.
13. If a CWT or a BWT interrupt occurs, then the software should read the RCV\_STATUS register to determine if the error was caused by a CWT, BWT, or a BGT violation. The software should clear the CWT, BWT, BGT interrupt by writing a "1" to the CWT, BWT, BGT bit in the RCV\_STATUS register.

#### 11.2.4.1.6 Configuring SIM Linear Redundancy Check (LRC) Block

The following is a list of items that need to be performed in order to configure the SIM Linear Redundancy Check Block for operation:

1. Enable the LRC block by using the CNTL register.
  - a. Use the LRCEN bit to enable the LRC block.
  - b. Use the XMT\_CRC\_LRC bit to enable the transmission of the LRC Character after the last character in the Transmit FIFO is sent. Refer to the T=1 programming model for more details.

### 11.2.4.1.7 Configuring SIM Cyclic Redundancy Check (CRC) Block

The following is a list of items that must be performed to configure the SIM Cyclic Redundancy Check Block for operation:

1. Enable the CRC block by using the CNTL register.
  - a. Use the CRCEN bit to enable the CRC block.
  - b. Use the XMT\_CRC\_LRC bit to enable the transmission of the CRC Characters after the last character in the Transmit FIFO is sent. Refer to the T=1 Programming model for more details.

### 11.2.4.2 Using the SIM Receiver

Once the SIM has been properly configured (such as correct baud rate and correct data format), SIM receptions can be enabled by setting the receive enable bit, RCV\_EN, in the ENABLE register. As bytes are received, they will be placed in the 288 byte deep receive data FIFO. Unread bytes can be accessed from this FIFO at any time. There is no need to disable the receiver to access the FIFO. The FIFO should only be read when the receive FIFO data flag, RFD, in the RCV\_STATUS register is set. The RFD flag, which cannot create an interrupt, is high any time there is at least one unread byte in the receive FIFO. If the receive FIFO is read when RFD is low, it will simply produce the last byte read.

The receive data register full flag, RDRF, in the RCV\_STATUS register can be used to determine when the receive FIFO has reached a given threshold value. This flag will create an interrupt if the RIM bit in the INT\_MASK register is clear. To control at which point RDRF is set, program the receive data threshold, RDT, in the RCV\_THRESHOLD register. If the number of unread bytes in the receive FIFO is equal to or greater than the value set by RDT, RDRF will be set.

#### NOTE

A value of 0x0 in RDT implies that there must be 288 unread bytes in the receive FIFO to trigger RDRF.

The standard flow for receiving bytes from the SIM card is to set RDT to the appropriate value, wait for RDRF to cause an interrupt (RIM clear), and then read bytes out of the receive FIFO as long as RFD is high. In addition to checking RFD between every byte, it is also recommended that software check for the existence of a set OEF flag as well.

### 11.2.4.2.1 Receive Parity Errors and Parity NACK Generation

The SIM receiver checks every byte received for proper parity. The IC control bit in the DATA\_FORMAT register controls whether it checks for odd parity or even parity. When checking for odd parity, the number of logic ones contained in the 9 received bits (8 data bits and 1 parity bit) should be odd. Likewise, when checking for even parity, the number of logic ones contained in the 9 received bits (8 data bits and 1 parity bit) should be even.

If NACK generation on errors is disabled (ANACK = 0 in the CNTL register), the PORTx\_PE bit will be set when the SIM receiver detects a parity error, the received data byte and its PORTx\_PE bit are placed into FIFO. There is no need to clear the parity error flag in the FIFO. It is simply overwritten the next time a byte is received into that position of the FIFO. A parity error cannot cause an interrupt, and it is up to the software to discard data bytes with parity errors.

If NACK generation on errors is enabled (ANACK = 1), the SIM can automatically request the SIM card to re-send a byte that has a parity error by generating a NACK pulse on the SIM XMT pin. In this case, Bytes with parity errors are discarded and will not be placed into the FIFO.

To control NACK generation by the SIM receiver use the RTH[3:0], Receive NACK threshold, in the RCV\_THRESHOLD register. This set of bits specifies the number of consecutive NACK's generated by the SIM module on a received byte, before generating an RTE (receive threshold interrupt flag) in the RCV\_STATUS register. The RTE flag would also force the SIM port to power down the card if the SAPD0,1 bit is set in the PORT0,1\_CNTL register.

#### NOTE

The ANACK bit must be set in the CNTL register to enable this feature. The control bit ANACK is also used in initial character mode to enable the retransmission of initial characters in the event that an invalid initial character is received.

When a valid character has been received by the SIM, the internal counter keeping track of the number of NACK's transmitted on the current byte resets to zero. Clearing the receive threshold error (RTE) bit would also clear that counter.

When generating a NACK pulse, the SIM will generate the low pulse starting at 10.5 ETUs and lasting for 1 ETU.

### 11.2.4.2.2 Receive Frame Errors

The SIM receiver checks every byte received for a proper stop bit. A stop bit should exist during at least the first half of the 11th ETU time after the start of the character. If this is not true, a frame error is flagged. When a frame error is detected on a given byte, the

PORTx\_FE bit for that byte is set in the FIFO. The PORTx\_FE flag for each byte is read out of the FIFO when the data itself is read. There is no need to clear the frame error flag in the FIFO. It is simply overwritten the next time a byte is received into that position of the FIFO. A frame error cannot cause an interrupt, nor can it create a NACK pulse to the receiver asking for a retransmission of the corrupted data.

#### 11.2.4.2.3 Receive Overrun Errors and Overrun NACK Generation

When there already exists 288 unread bytes in the FIFO, a received character will cause the SIM receiver to flag an overrun condition. This condition will always set the overrun error flag, OEF in the RCV\_STATUS register. The received byte will be discarded leaving the 288 unread bytes in the FIFO unaltered.

It is possible for the SIM to automatically request that the SIM card re-send the byte that caused the overrun condition by generating a NACK pulse on the SIM XMT pin. The SIM will generate a NACK pulse for the byte that caused the overrun condition if the control bit ONACK in the CNTL register is set. In this case, the existence of an OEF flag does not indicate the loss of data, but rather a NACK (that is, retransmission request) due to a full receive FIFO. As opposed to transmit NACK generation, there is no limit to the number of times an overrun condition will cause a NACK other than to disable ONACK itself. When generating a NACK pulse, the SIM will generate the low pulse starting at 10.5 ETUs and lasting for 1 ETU.

If the control bit ONACK is clear, the existence of a high OEF flag indicates the loss of data. The OEF flag can create an interrupt if the OIM bit in the INT\_MASK register is clear.

To clear the OEF flag, software must simply write a "one" to the OEF bit position in the RCV\_STATUS register. A high OEF flag has no effect on the operation of the SIM receiver other than to create an interrupt if OIM is clear.

#### 11.2.4.2.4 Using Initial Character Mode and Resulting Receive Data Formats

The SIM receiver supports the detection of special characters that allow it to determine what data format is being used by the connected SIM card. When placed in initial character mode, the SIM expects to receive one of two potential values that it will use to set the data format control bit, IC, in the DATA\_FORMAT register.

The two possible data formats are inverse convention and direct convention. Essentially, inverse convention differs from direct convention in that the order of the data is flipped msb for lsb, and the data bits and parity bit are logically inverted. When receiving inverse convention data, the transformation of the data back to direct convention format is done in hardware, including the inversion of the data and parity bits.

To place the SIM into initial character mode, set the ICM bit in the CNTL register. Once a valid initial character is received, the IC bit in the DATA\_FORMAT register will be set accordingly by the hardware, and the ICM bit will be cleared. Software can read the state of the IC bit to determine which mode the SIM is currently using.

The 0x3B (as decoded by direct convention) with parity bit high will cause direct convention to be used (IC set to logic 0), whereas a 0x3F (as decoded by inverse convention) with parity bit high will cause inverse convention to be used (IC set to logic 1).

When the receiver is in initial character mode, all received bytes will continue to be placed into the receive FIFO whether they be valid initial characters or not. If a valid initial character is received that causes the data format being used to change, all subsequent bytes will be decoded with that format before being placed into the FIFO, including the initial character byte itself. That is, if the IC bit is low, and the correct initial character for setting inverse convention is received, that character and all subsequently received characters will be stored in the FIFO after having been decoded using inverse convention (for example, the initial character will be stored as 0x3F).

If the receiver is in initial character mode (ICM is high), and an invalid initial character is received, the SIM can be configured to automatically request that the initial character be retransmitted by setting the ANACK control bit in the CNTL register. When generating a NACK pulse, the SIM will generate the low pulse starting at 10.5 ETUs and lasting for 1 ETUs. The invalid initial character will be placed into the receive FIFO and marked with a parity error to signify that this is an invalid initial character.

#### **11.2.4.2.5 Initial Character Mode Programming Notes**

The usage of the initial character mode requires close attention to the programming model. There is a condition where a parity error in the initial byte for direct convention (0x3B) could be decoded as what appears to be a valid initial character for inverse convention (that is, 0x3F). The SIM module will not recognize this as a valid initial character for inverse convention and will mark the character by setting the parity error flag. The software must look for the existence of a parity error before recognizing a character as a valid initial character.

### 11.2.4.2.6 Automatic Receiver Mode

The SIM module has an automatic receive mode that inhibits the data being transmitted by the SIM module from entering the SIM receive buffer through the feedback path of the SIM data pin. The SIM module receiver should normally be enabled while the transmitter is operational. Automatic receive mode saves the software from having to actively manage the transition from transmitter to receiver. The auto receive mode is always active whenever the receiver is enabled.

### 11.2.4.2.7 Using the SIM Receiver with "T=1" SIM Cards

The SIM module provides hardware support for "T=1" type SIM cards. These type of cards present several requirements above and beyond the standard "T=0" cards. The features provided to meet the requirements that pertain to the SIM receiver are as follows:

- 11 ETU Characters
  - "T=1" cards can transmit with character lengths of 11 ETUs (that is, one STOP bit). The SIM module provides the RCVR11 bit in the GUARD\_CNTL register in order to configure the receiver state machine to accept 11 ETU characters.
- Character Wait Time Counter
  - The character waiting time (CWT) is defined as the time between the start bits of two consecutive characters received from the SmartCard. The value of CWT can range from 12 ETU to 32779 ETU. The SIM module provides a 16-bit counter with programmable comparator clocked at the ETU bit rate to identify when the CWT has been exceeded by the SIM card.
- Block Waiting Time
  - The block waiting time (BWT) is defined as the maximum time between the start bits of the last character of a transmitted block and the first character of the next received block. The block wait time must not exceed a value that is programmable. The SIM module provides a 32-bit Block Wait Timer that can be used to identify when the BWT has been violated (divided in two registers).
- Block Guard Time
  - The block guard time (BGT) is defined as the minimum delay between the start bits of the last character of a transmitted block and the first character of the next received block. The block guard must be greater than a value that is programmable. The SIM module provides a 16-bit Block Guard Timer that can be used to identify when the BGT has been violated.
- Error Detection Code
  - "T=1" cards can specify LRC or CRC error detection codes to be used. The SIM module provides hardware support for both the LRC and CRC operations.

### 11.2.4.3 Using the SIM Transmitter

Once the SIM has been properly configured (such as data XMT enabled, correct baud rate, and correct data format), the transmitter can be enabled by setting the XMT\_EN bit in the ENABLE register. If data had been previously written to the transmit FIFO, the transmitter will begin to send the first character. If no data is written to the transmit FIFO before enabling the transmitter, then the transmitter will wait until the first character is written before beginning transmission. Clearing the XMT\_EN bit while the transmitter is in operation, will halt any transmission in progress, flush the transmit FIFO, and reset the transmit state machine.

Data can be written to the transmit FIFO at any time.

The transmit data threshold flag, TDTF, in the XMT\_STATUS register can be used to determine when the transmit FIFO has reached a given threshold value. This flag will create an interrupt if the TDTFM bit in the INT\_MASK register is clear. To control at which point TDTF is set, program the transmit data threshold, TDT[3:0], in the XMT\_THRESHOLD register. If the number of bytes remaining in the transmit FIFO is equal to or less than the value set by TDT[4:0], TDTF will be set.

#### NOTE

A value of 0x0 in TDT[3:0] implies that the transmit FIFO must be empty to trigger TDTF.

The value in TDT[3:0] can be changed at any time to alter this threshold level. The comparison between the number of remaining bytes in the transmit FIFO and the value set by TDT[3:0] is continuously updated so that any change in either will be immediately reflected in the state of TDTF. Unlike the RDRF flag for the receive FIFO, TDTF is latched and remains set until the software writes a 1 to the TDTF bit location in the XMT\_STATUS register. For instance, if TDT[3:0] is set to 5, and there are 6 bytes remaining in the FIFO, changing TDT[3:0] to 6 will immediately cause TDTF to be set. However, setting TDT[3:0] back to 5 will not cause TDTF to clear.

The standard flow for transmitting bytes from the SIM card is to set TDT[3:0] to the appropriate value, write up to 16 bytes to the transmit FIFO, enable the transmitter, wait for TDTF to cause an interrupt (TDTFM clear), and then write additional bytes to the transmit FIFO.

#### NOTE

For the SIM module to transmit successfully, the transmit pin must be connected to the receive pin of the same port. This connection is necessary for the SIM to decode transmit NACKs sent to it by the SIM card. Without this connection, all transmissions will appear to have a NACK thereby causing the first byte to be transmitted continuously. When operating in

external one wire interface mode (3VOLT0 or 3VOLT1), this connection is made internal to the SoC.

#### 11.2.4.3.1 Transmit Data Formats

There are two possible data formats that the SIM module uses when transferring data to the SIM: card - inverse convention or direct convention. The format used depends on the state of inverse convention bit (IC in the DATA\_FORMAT register). Software can set the IC bit, or it can be set automatically by hardware when using the initial character mode.

#### 11.2.4.3.2 Transmit NACK

The SIM transmitter can respond to NACKs created by the SIM card. A NACK will be decoded if the SIM card creates a logic low level on the SIM receive pin during the STOP bit time at the end of a transmitted byte. To prevent a situation where the SIM interface is stalled by an infinite number of NACK pulses on a given byte, the SIM module can be configured to limit the number of times it will respond to NACKs. The XTH[3:0] control field in the XMT\_THRESHOLD register allows software to set a threshold on the number of times a given byte will be retransmitted. If the threshold is reached, a transmit threshold error, XTE in the XMT\_STATUS register, is asserted.

When XTE is set, the SIM transmitter is halted, and all pending transfers are aborted, and the TC, ETC, AND TFE flags are set. All bytes remaining in the transmit FIFO are lost. There is no way to restart the transmission on the next byte in the FIFO. The transmitter remains frozen until XTE is cleared by software. The only way to clear XTE is to write a 1 to the XTE bit in the XMT\_THRESHOLD register. The XTE flag can create an interrupt if the XTM mask in the XMT\_THRESHOLD register is clear.

It is possible to disable the detection of NACKs from the SIM card by setting XTH[3:0] to 0x0. By setting XTH[3:0] to 0x1, it is possible to disable all retransmissions while still setting XTE on the first NACK received. In general, XTE is set on the NACK that causes the threshold set by XTH[3:0] to be reached. This final NACK will not cause a retransmission, whereas all previous NACKs will cause a retransmission.

#### 11.2.4.3.3 Transmit Guard Time

The time between data bytes sent from the SIM transmitter can be altered using the transmit guard time control. By default, the minimum time between start bits of successive transmitted bytes is 12 ETUs (Elementary Time Units). An ETU is equivalent in time to 1 bit time. Therefore, the amount of time an ETU consumes is determined by the baud rate chosen. The 12 ETUs that form the default character transmission time consist of a start bit, 8 data bits, a parity bit and two stop bits. The number of stop bits (idle bits) can be extended by an integer number of ETUs. The number of additional

ETUs can be programmed directly into the GETU[7:0] bits of the GUARD\_CNTL register. Programming the GETU[7:0] bits to 0xFF will configure the SIM transmitter to use only one stop bit for each character transmission.

#### 11.2.4.3.4 Using SIM Transmit with "T=1" SIM Cards

The SIM module provides hardware support for "T=1" type SIM cards. These type of cards present several requirements above and beyond the standard "T=0" cards. The features provided to meet the requirements that pertain to the SIM transmitter are as follows:

- 11 ETU Characters
  - The SIM module transmitter has a programmable guard time register that allows the programmer to specify the number of ETUs between character transmissions. Programming a value of 255 (0xFF) in the GETU[7:0] bits in the GUARD\_CNTL register will set the number of ETUs per character transmitted to 11.
- Character Waiting Time
  - The character waiting time (CWT) is defined as the time between the start bits of two consecutive characters. The value of CWT can range from 12 ETU to 32779 ETU. The time between transmitted characters is controlled by the programmable guard time in the GUARD\_CNTL register. However, the time between the last byte in the transmit FIFO, and the next transmitted byte can be largely affected by software response time to the transmit interrupts. The SIM transmitter provides a Transmit FIFO threshold (TDTF) interrupt to signal the system when the expected number of characters have been transmitted from the transmit FIFO. The minimum CWT is achieved only if the software can respond to the TDTF interrupt and write new data to the transmit FIFO before the last character in the Transmit FIFO has been sent.
- Block Waiting Time
  - The block waiting time (BWT) is defined as the maximum time between the start bits of the last character of a transmitted block and the first character of the next received block. The value of BWT is always greater than 1800 ETU. The SIM transmitter provides a General Purpose Counter that can be used to track the BWT. The BWT is purely determined by software response time to the transmit interrupts.
- Block Guard Time
  - The block guard time (BGT) is defined as the minimum delay between the start bits of the last character of a transmitted block and the first character of the next received block. The value of BGT is 22 ETU. The SIM module supports the BGT by providing the ability to generate an interrupt when the last byte is received, and transmitting within 2 ETU after the XMT\_EN bit is set. The BGT

will be determined by the speed at which the software can react to an interrupt and enable the transmitter.

- Error Detection Code
  - "T=1" cards can specify LRC or CRC error detection codes to be used. The SIM module provides hardware support for both the LRC and CRC operation.

### 11.2.4.4 Suggested "T=1" Compliant Programming Model

This section describes the suggested programming model for supporting "T=1", "T=0", and known "special" cards using the SIM module on the device. This should be used as a rough guide for how to configure the SIM module for use with SIM cards specified by ISO 7816-3 and EMV. Some details are not addressed. Other uses for some of the SIM features are not included (for example, GP Counter uses for some ISO timing requirements).

#### 11.2.4.4.1 Answer To Reset (ATR) Detection

The first step to communicating with a SIM card is to provide power and a clock signal to the card. Once the card is detected as present (using the presence detect features, or some other method), the SIM card should be powered up according to the power up sequence specified in the ISO 7816-3 specification.

1. Apply voltage to the SIM card by setting the SVEN0 or SVEN1 bit in the PORTx\_CNTL register
2. Select the appropriate clock frequency for the SIM card by programming the CLK\_PRESCALER[7:0] register.
3. Enable the clock to the SIM card by setting the SCEN0 or SCEN1 bit in the PORTx\_CNTL register.
4. Remove the card from reset by setting the SRST0 or SRST1 bit in the PORTx\_CNTL register.

The first communication between the SIM card and the SIM module will be a block of data sent from the SIM card to the SIM module after the card is powered and the card reset is removed. This block is called the Answer To Reset (ATR). To receive the ATR, the SIM module should be configured for 12 ETU character reception. According to the ISO 7816-3 spec, both "T=0" and "T=1" cards will communicate initially using 12 ETU character durations.

#### NOTE

We are aware of some card manufacturers that communicate at 11.5 ETU character durations (Geldkarte).

This will complicate the initial card detection sequence shown below.

5. Clear RCVR11 bit in the GUARD\_CNTL register

The next item to configure for ATR reception is the NACK capability of the SIM module. The ISO 7816-3 spec allows the SIM module to NACK any communication errors that occur during the initial communication at 12 ETU.

**NOTE**

The Europay Mastercard and VISA (EMV) cards are similar to "T=1", but do not allow the SIM module to NACK during the initial communication. This will again complicate the initial card detection sequence shown below.

6. Set ANACK bit in the CNTL register to enable NACK generation

In order for the SIM module to notify when characters are received, the receive interrupt(s) can be enabled. A threshold can be set for the number of characters to receive before generating an interrupt.

7. Enable RDRF and OEF interrupts by setting RIM and OIM bits in INT\_MASK register

8. Set desired threshold for received characters by writing RDT in RCV\_THRESHOLD register.

The SIM should be setup to perform in initial character mode. This will cause the hardware to identify the first valid character sent during the ATR as an initial character. This character will automatically configure the hardware for the data convention used by the SIM card.

9. Set Initial Character Mode by setting the ICM bit in the CNTL register

The ISO 7816-3 spec requires that SIM cards meet certain timing restrictions. One of these is the time from the deassertion of the card reset to the beginning of the ATR sequence. The SIM module General Purpose Counter can be used to verify that the SIM card begins its ATR within the 400 to 40,000 clock cycle range.

1. Set General Purpose Counter Comparator to 0x9C40 using GPCNT register.

2. Enable General Purpose Counter Interrupt by clearing GPCNTM in INT\_MASK register.

3. Enable General Purpose Counter by programming the GPCNT\_CLKSEL[1:0] bits to 01 so the card clock is used for counting.

The ISO7816-3 spec states that the maximum allowed time between two characters during the ATR is 9600 ETUs (Initial Waiting Time). The Character Wait Time Counter should be setup to detect any errors for this condition.

1. Set Character Wait Time Counter Comparator to 9600 using the CHAR\_WAIT register
2. Enable the Character Wait Time Counter Interrupt by clearing CWTM in INT\_MASK register
3. Enable the Character Wait Time Counter by setting the CWTEN bit in the CNTL register

The last step in preparing for ATR reception is to enable the receiver.

4. Set RCV\_EN bit in ENABLE register

The SIM module will generate interrupts once a threshold number of characters is received. The software should react to these interrupts and read the characters from the receive FIFO (RCV\_BUF) until the complete ATR has been received. If a General Purpose Counter interrupt occurs before the final ATR character is received, then the card should be deactivated according to the ISO 7816-3 spec. Otherwise, once a valid ATR is received, the software will know from the ATR information the specific characteristics for this card (refer to the ISO 7816-3 spec for details).

#### 11.2.4.4.2 Programming Considerations for Geldkarte Cards

There is at least one manufacturer of SIM cards (Geldkarte) that we know of that does not send the ATR in 12 ETU mode or support NACKs. This creates an issue with detecting a valid ATR from a SIM card. Since any kind of card can be attached to the SIM module, the software and hardware do not know how to begin communication. Basically, if the card fails to send a valid ATR on the first try, disable NACKs, configure the SIM module for 11 ETU and try again. The software should toggle between 12 and 11 ETU modes with and without NACKs enabled until a valid ATR is received, or the number of attempts to communicate passes a predetermined error threshold. The figure below shows the flow chart for the suggested Geldkarte Compliant SIM Initialization.

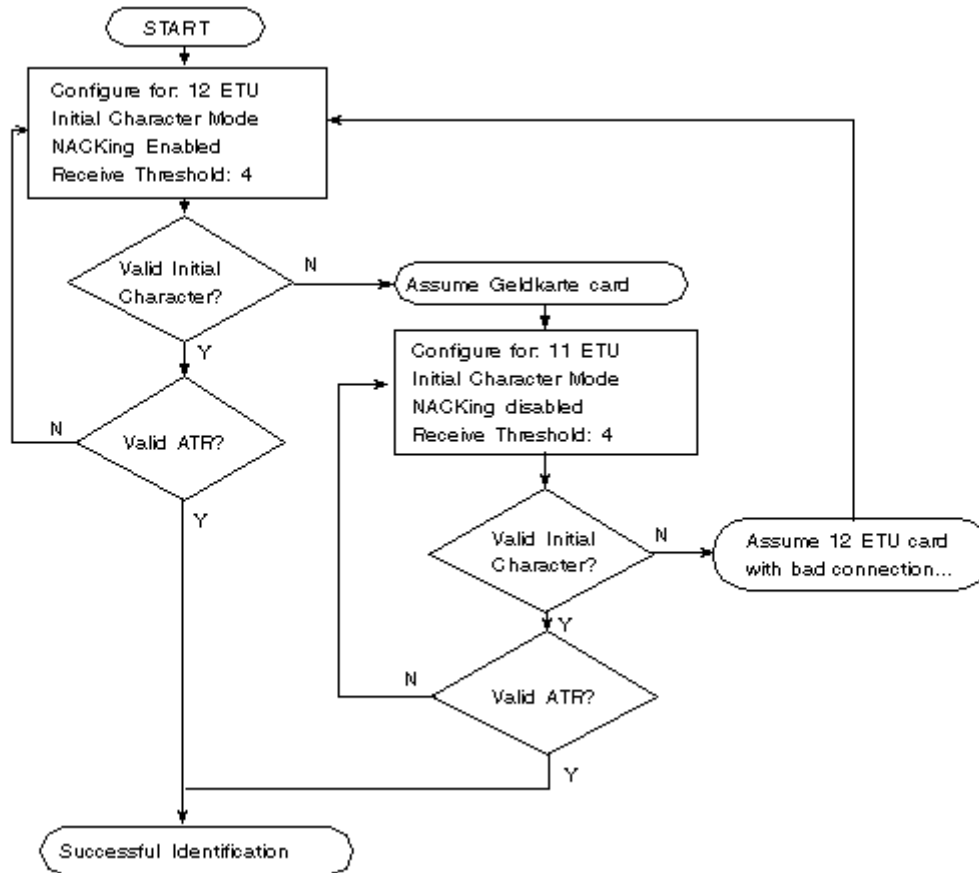

Figure 11-51. Suggested "T=1", EMV, Geldkarte Compliant SIM Initialization

### 11.2.4.4.3 Programming Considerations for T=0 SIM Cards

If the card is of type T=0, the software should adjust the following parameters according to the information in the ATR:

1. Adjust the baud rate by changing the values of BAUD\_SEL[2:0] and SAMPLE12 in the CNTL register
2. Adjust the guard time between characters by changing the value of GETU[7:0] in the GUARD\_CNTL register
3. Adjust NACK capability by modifying the values of the ONACK and ANACK bits in the CNTL register
4. Adjust the stop clock polarity by modifying the values of the SCSP0 or SCSP1 bits in the PORTx\_CNTL register
5. Adjust the level of transmit NACK re-transmissions allowed by modifying the value of the XTH[3:0] bits in the XMT\_THRESHOLD register
6. Adjust the level for the Receive NACK threshold by modifying the RTH[3:0] bits in the RCV\_THRESHOLD register.

If a negotiation with the SIM card is desired, the software sends a PPS response to the SIM card. To send the response, the following steps should be performed:

1. Set the desired transmit FIFO threshold level by writing the TDT[3:0] bits in the XMT\_THRESHOLD register
2. Write the characters to be sent as response (max 16) to the transmit FIFO using the XMT\_BUF register
3. Clear all transmit interrupt flags in the XMT\_STAT register by writing a one to them
4. Enable the transmit interrupts desired by clearing the mask bits in the INT\_MASK register. If more than 16 character are to be sent, it is suggested that the TDTF interrupt be used to signify when to write more characters to the transmit FIFO. This results in the most efficient transfer times to the SIM card.
5. Enable the transmitter by setting the XMT\_EN bit in the ENABLE register

At this point, the SIM module will transmit the characters in the transmit FIFO. If more than 16 characters are to be sent, the transmit threshold interrupt will be set when the threshold number of characters are remaining in the FIFO. The software can then write an additional number of characters to be sent without interrupting transmission to the SIM card.

Once the transmission is complete, the SIM module should be completely configured for standard operation with the T=0 SIM card. The software can continue to service RDRF interrupts for received characters, and TDTF interrupts for transmitted characters.

#### 11.2.4.4.4 Programming Considerations for T=1 SIM Cards

If the card is of type T=1, the software should adjust the following parameters according to the information in the ATR:

1. Adjust the baud rate by changing the values of BAUD\_SEL[2:0] and SAMPLE12 in the CNTL register
2. Adjust the guard time between characters by changing the value of GETU[7:0] in the GUARD\_CNTL register. Setting GETU[7:0] to 0xFF configures the SIM transmitter for 11 ETU transmissions
3. Disable NACK capability by clearing the ONACK and ANACK bits in the CNTL register. T=1 cards do not allow NACKs.
4. Adjust the stop clock polarity by modifying the values of the SCSP0 or SCSP1 bits in the PORTx\_CNTL register
5. Set Character Wait Time Counter Comparator to value specified in the ATR by using the CHAR\_WAIT register
6. Enable the Character Wait Time Counter Interrupt by clearing CWTM in INT\_MASK register

7. Enable the Character Wait Time Counter by setting the CWTEN bit in the CNTL register
8. Enable CRC or LRC error checking according to the ATR information by setting either the CRCEN or LRCEN bit in the CNTL register. These bits will never be set at the same time!

For T=1 cards, the ATR is sent using a T=0 type of structure (12 ETU, no LRC or CRC). If a negotiation with the SIM card is desired, the software will send a PPS response to the SIM card. Otherwise, the protocol is initiated with a block transfer from the SIM module. In order to send the response or the first block, the following steps should be performed:

9. Set the desired transmit FIFO threshold level by writing the TDT[3:0] bits in the XMT\_THRESHOLD register
10. Write the characters to be sent as response (max 16) to the transmit FIFO using the XMT\_BUF register
11. Clear all transmit interrupt flags in the XMT\_STAT register by writing a 1 to them
12. Enable the transmit interrupts desired by clearing the mask bits in the INT\_MASK register. If more than 16 character are to be sent, it is suggested that the TDTF interrupt be used to signify when to write more characters to the transmit FIFO. This results in the most efficient transfer times to the SIM card.
13. Enable the transmission of the error checking characters (LRC or CRC) by setting the XMT\_CRC\_LRC bit in the CNTL register.

#### **NOTE**

If the card supports PPS, the software may not be allowed to send the LRC/CRC information until the PPS exchange is completed. If so, do not set the XMT\_CRC\_LRC bit during the PPS exchange.

14. Enable the transmitter by setting the XMT\_EN bit in the ENABLE register

At this point, the SIM module will transmit the characters in the transmit FIFO. If more than 16 characters are to be sent, the transmit threshold interrupt will be set when the threshold number of characters are remaining in the FIFO. The software can then write an additional number of characters to be sent without interrupting transmission to the SIM card.

Once the transmission is complete, the SIM module should be completely configured for standard operation with the T=1 SIM card. The software can continue to service RDRF interrupts for received characters, and TDTF interrupts for transmitted characters.

### 11.2.5.1 SIM Port1 Control Register (SIMx\_PORT1\_CNTL)

See the figure below for illustration of valid bits in the SIM Port1 Control Register and the table below for description of the bit fields.

Address: Base address + 0h offset

**SIMx\_PORT1\_CNTL field descriptions**

Field	Description
31–8 -	This field is reserved. Reserved
7 SFPD1	Auto Power Down port1. Writing a "1" to this location will start the auto power down sequence for port 1. This bit will autoclear. A read of this bit will give a "0".  0 No effect 1 Start Auto Power down
6 VOLT3_1	External one wire interface for SIM Card port1. Used to configure the Port 1 transmit pin as bi-directional. This allows the Port 1 Receive pin to be re-used as General Purpose I/O. This operation is restricted to bi-directional data SIM cards only.  This bit should not be changed while the receiver or transmitter is enabled!  0 Port1 uses both rcv and xmt pins 1 Port1 XMT pin bidirectional. Port1 RCV PIN unused

Table continues on the next page...

**SIMx\_PORT1\_CNTL field descriptions (continued)**

<b>Field</b>	<b>Description</b>
5 SCSP1	SIM Card Clock Stop Polarity Port1. Used to control the polarity of the idle SIM clock when the clock is disabled by SCEN1. It will be forced low by hardware during the auto power down sequence. This forces the clock be a logic 0 when stopped by auto power down as required by ISO 7816 spec.  0 Clock is logic 0 when stopped by SCEN1 1 Clock is logic 1 when stopped by SCEN1
4 SCEN1	SIM card Clock Enable Port 1. Used to enable/disable the clock to the SIM card. It can be forced low by hardware during the auto power down sequence.  0 SIM Card Clock Disabled Port1 1 SIM Card Clock Enabled Port1
3 SRST1	SIM card Reset. Used to control state of reset line to the SIM card. It can be forced low by hardware during the auto power down sequence. SIM card reset signals are active low.  0 SIM Card reset Port1 inactive (default) 1 SIM Card reset Port1 active
2 STEN1	SIM card Transmit Enable Port 1. Used to enable/disable the XMT data to the SIM card. It can be forced low by hardware during the auto power down sequence.  0 Port1 Transmit Data is forced to zero (default) 1 Port 1 Transmit Data controlled by SIM module
1 SVEN1	SIM card Vcc Enable Port 1. Used to control the state of the SVEN1 pin on SIM card port 1. The SVEN1 pin controls the SIM card V <sub>CC</sub> enable in the power management chip. It can be forced low by hardware during the auto power down sequence.  0 SIM card Voltage Port 1 disabled (default) 1 SIM card Voltage Port 1 enabled
0 SAPD1	SIM card Auto Power Down Port 1. Used to enable/disable the auto power down function for port 1. It will be forced low at the end of the auto power down sequence.  0 Auto power down Port 1 disabled (default) 1 Auto power down Port 1 enabled

### 11.2.5.2 SIM Setup Register (SIMx\_SETUP)

See the figure below for illustration of valid bits in the SIM Setup Register and the table below for description of the bit fields.

Address: Base address + 4h offset

**SIMx\_SETUP field descriptions**

Field	Description
31–2 -	This field is reserved. Reserved
1 SPS	<b>SIM card Port Select.</b> Controls which port the SIM interface uses. <b>NOTE:</b> The AMODE bit must be zero when the SPS bit is set to 1. 0 Port 0 Enabled (default) 1 Port 1 Enabled
0 AMODE	<b>Alternate SIM Card Mode enable.</b> Enables an alternate SIM module to control SIM card Port 1. <b>NOTE:</b> The SPS bit must be 0 to give the alternate SIM module control. 0 Alternate Port Disabled (default) 1 Alternate Port Enabled

### 11.2.5.3 SIM Port 1 Detect Register (SIMx\_PORT1\_DETECT)

See the figure below for illustration of valid bits in the SIM Port1 Detect Register and the table below for description of the bit fields.

Summary:

spds1 determines which edge transition of the SIMPD1 pin is used for SIM card presence detection. Presence detection can be used to determine if the card has been inserted or removed. The occurrence of the SIMPD1 edge specified by spds1 will cause the following: sdi1 to be set; if the sdim1 mask is clear, an interrupt on SIMIRQ\_N; and if sapd1 in the PORT1\_CNTL register is set, an auto power down sequence to begin. If SIM card insertion is expected, sapd1 can be set low to avoid the auto power down sequence. There is no auto power up sequence. The bit spdp1 can be used to determine the current state of the SIMPD1 pin.

Address: Base address + 8h offset

### SIMx\_PORT1\_DETECT field descriptions

Field	Description
31–4 -	This field is reserved. Reserved
3 SPDS1	<b>SIM Presence Detect Select Port 1.</b> Controls which edge of the SIMPD1 pin is used to detect the presence of the SIM card.  0 Falling edge of SIMPD1 Input (default) 1 Rising edge of SIMPD1 Input
2 SPDP1	<b>SIMPD1 input pin status.</b> This bit reflects the state of the SIMPD1 pin. It is not a latched register bit, but instead a synchronized version of the state of the SIMPD1 pin itself.

Table continues on the next page...

**SIMx\_PORT1\_DETECT field descriptions (continued)**

Field	Description
	0 SIMPD1 pin is logic low 1 SIMPD1 pin is logic high
1 SDI1	<b>SIM Detect Interrupt Flag Port 1.</b> Status flag to indicate the insertion or removal of a SIM card has been detected on port 1. Can create an interrupt to the MCU if SDI1 is low. Write a "1" to this bit to clear.  0 No insertion or removal of SIM card detected on Port 1(default) 1 Insertion or removal of SIM card detected on Port 1
0 SDIM1	<b>SIM Detect Interrupt Mask Port 1.</b> Interrupt mask for the sdi1 interrupt flag.  0 SDI1 enabled 1 SDI1 masked (default)

**11.2.5.4 SIM Transmit Buffer Register (SIMx\_XMT\_BUF)**

See the figure below for illustration of valid bits in the SIM Transmit Buffer Register and the table below for description of the bit fields.

Address: Base address + Ch offset

**SIMx\_XMT\_BUF field descriptions**

Field	Description
31–8 -	This field is reserved. Reserved
XMT	<b>Transmit Buffer.</b> Write to the next available location in the transmit buffer.

### 11.2.5.5 SIM Receive Buffer Register (SIMx\_RCV\_BUF)

See the figure below for illustration of valid bits in the SIM Receive Buffer Register and the table below for description of the bit fields.

Address: Base address + 10h offset

Bit	31	30	29	28	27	26	25	24		23	22	21	20	19	18	17	16

#### SIMx\_RCV\_BUF field descriptions

Field	Description
31–11 -	This field is reserved. Reserved
10 CWT	<b>CWT flag.</b> The CWT indicates that this byte was late. It is not necessary to clear the byte since it is overwritten by the next byte received into that location of the FIFO.  0 Byte was on time 1 Byte was late
9 FE	<b>Frame Error flag.</b> The FE flag indicates whether a frame error was detected during the reception of the corresponding byte read in the RCV field. The FE flag cannot create an interrupt. It need not be cleared since it will be overwritten by the next byte received into that location of the FIFO.  0 Byte contains no framing error (default) 1 Byte contains a framing error
8 PE	<b>Parity Error flag.</b> The PE flag indicates whether a parity error was detected during the reception of the corresponding byte read in the RCV field. The PE flag cannot create an interrupt. It need not be cleared since it will be overwritten by the next byte received into that location of the FIFO. A parity error can create a NACK pulse.  0 Byte contains no parity error (default) 1 Byte contains a parity error
RCV	<b>Receive buffer.</b> Read from the next location in the receive buffer.

### 11.2.5.6 SIM Port0 Control Register (SIMx\_PORT0\_CNTL)

See the figure below for illustration of valid bits in the SIM Port0 Control Register and the table below for description of the bit fields.

Address: Base address + 14h offset

**SIMx\_PORT0\_CNTL field descriptions**

Field	Description
31–8 -	This field is reserved. Reserved
7 SFPD0	Auto Power Down port0. Writing a "1" to this location will start the auto power down sequence for port 0. This bit will autoclear. A read of this bit will give a "0".  0 No effect 1 Start Auto Power down
6 VOLT3_0	External one wire interface for SIM Card port0. Used to configure the Port 0 transmit pin as bi-directional. Only bi-directional data SIM cards are supported. Hence user should program this bit to 1.  This bit should not be changed while the receiver or transmitter is enabled!  Port0 uses both RCV and XMT pins 1 Port0 XMT pin bidirectional. Port0 rcv pin unused

Table continues on the next page...

**SIMx\_PORT0\_CNTL field descriptions (continued)**

<b>Field</b>	<b>Description</b>
5 SCSP0	SIM Card Clock Stop Polarity port0. Used to control the polarity of the idle SIM clock when the clock is disabled by SCEN0. It will be forced low by hardware during the auto power down sequence. This forces the clock to be a logic 0 when stopped by auto power down as required by ISO 7816 spec.  0 Clock is logic 0 when stopped by scen0 1 Clock is logic 1 when stopped by scen0
4 SCEN0	SIM card Clock Enable Port 0. Used to enable/disable the clock to the SIM card. It can be forced low by hardware during the auto power down sequence.  0 SIM Card Clock Disabled Port 0 1 SIM Card Clock Enabled Port 0
3 SRST0	SIM card Reset. Used to control state of reset line to the SIM card. It can be forced low by hardware during the auto power down sequence. SIM card reset signals are active low.  0 SIM Card reset Port0 inactive (default) 1 SIM Card reset Port0 active
2 STEN0	SIM card Transmit Enable Port 0. Used to enable/disable the XMT data to the SIM card. It can be forced low by hardware during the auto power down sequence.  0 Port0 Transmit Data is forced to zero (default) 1 Port 0 Transmit Data controlled by SIM module
1 SVEN0	SIM card V <sub>CC</sub> Enable Port 0. Used to control the state of the SVEN0 pin on SIM card port 0. The SVEN0 pin controls the SIM card V <sub>CC</sub> enable in the power management chip. It can be forced low by hardware during the auto power down sequence.  0 SIM card Voltage Port 0 disabled (default) 1 SIM card Voltage Port 0 enabled
0 SAPD0	SIM card Auto Power Down Port 0. Used to enable/disable the auto power down function for port 0. It will be forced low at the end of the auto power down sequence.  0 Auto power down Port 0 disabled (default) 1 Auto power down Port 0 enabled

### 11.2.5.7 SIM Control Register (SIMx\_CNTL)

See the figure below for illustration of valid bits in the SIM Control Register and the table below for description of the bit fields.

Address: Base address + 18h offset

**SIMx\_CNTL field descriptions**

Field	Description
31–16 -	This field is reserved. Reserved
15 BWTEN	<b>Block wait time enable.</b> Writing a "1" to this bit will enable the bwt and bgt functions. The bwt and bgt functions can then be individually selected using the interrupt mask.  0 Disable BWT, BGT 1 Enable BWT, BGT
14 xmt_crc_lrc	<b>Transmit CRC or LRC.</b> This bit specifies whether or not to transmit the redundancy checking data at the end of a transmission (that is, when the FIFO becomes empty).  0 No Redundancy check info transmitted (default) 1 Transmit LRC or CRC info when FIFO empties (whichever is enabled)
13 CRCEN	<b>CRC Enable.</b> This bit enables the calculation of the 16-bit CRC value for both receiver and transmitter. The result of the calculation is continuously compared to the expected remainder and reflected in the

*Table continues on the next page...*

## SIMx\_CNTL field descriptions (continued)

Field	Description
	<p>crcook bit in the RCV_STAT register. Clearing this bit resets the current CRC residual value in the SIM hardware.</p> <p>0 16-bit Cyclic Redundancy Checking disabled (default) 1 16-bit Cyclic Redundancy Checking enabled</p>
12 LRCEN	<p><b>LRC Enable.</b> This bit enables the calculation of the 8-bit LRC value for both receiver and transmitter. The result of the calculation is continuously compared to zero and reflected in the lrcok bit in the RCV_STAT register. Clearing this bit resets the current LRC value in the SIM hardware.</p> <p>0 8-bit Linear Redundancy Checking disabled (default) 1 8-bit Linear Redundancy Checking enabled</p>
11 CWTEN	<p><b>Character Wait Time Counter Enable.</b> Enables the character wait time counter. Clearing this bit resets the counter to zero.</p> <p>0 Character Wait time Counter off (default) 1 Character Wait time counter on</p>
10–9 gpcnt_clk_sel	<p><b>General Purpose Counter Clock Select.</b> Selects which clock source is used by SIM Module general purpose counter. The only way to reset the counter is to set these bits to zero. The counter will begin counting as soon as the clock input is selected and the clocks are enabled. These input clocks are enabled through other register bits of the SIM module (KILL_CLOCK, RCV_EN, and XMT_EN respectively).</p> <p>00 Disabled / Reset 01 Card Clock 10 Receive Clock 11 ETU Clock (transmit clock)</p>
8–6 baud_sel[2:0]	<p><b>SIM Baud Rate Select.</b> Selects the asynchronous baud rate divisor of the clock. When set to "111", the divisor is set to the value programmed in the DIVISOR register. This allows for more flexible baud rate determination.</p> <p>000 31 (512/1 Fi/Di) 001 32 (512/2 Fi/Di) 010 16 (512/4 Fi/Di) 011 8 (512/8 Fi/Di) 100 4 (512/16 Fi/Di) 101 2 (512/32 Fi/Di) 110 1 (512/64 Fi/Di) 111 DIVISOR Reg</p>
5 Sample12	<p><b>Sample12.</b> Set the third stage divider. This sets the corresponding sample rate which is the number of times a bit being received is sampled.</p> <p>0 divide by 8(default) 1 divide by 12</p>
4 -	<p>This field is reserved. Reserved</p>
3 ONACK	<p><b>Overrun NACK Enable.</b> Enables overrun NACK generation.</p> <p>0 NACK generation on overrun is disabled (default) 1 NACK generation on overrun is enabled</p>

Table continues on the next page...

**SIMx\_CNTL field descriptions (continued)**

Field	Description
2 ANACK	<b>Automatic NACK Enable.</b> Enables nack generation for parity errors or invalid initial characters when in ICM mode.  0 NACK generation on errors disabled 1 NACK generation on errors enabled (default)
1 ICM	<b>Initial Character Mode.</b> Enables initial character mode. Will be automatically cleared by hardware once a valid initial character is received.  0 Initial Character Mode disabled 1 Initial Character Mode enabled (default)
0 -	This field is reserved. Reserved

**11.2.5.8 SIM Clock Prescaler Register (SIMx\_CLK\_PRESCALER)**

See the figure below for illustration of valid bits in the SIM Clock Prescaler Register and the table below for description of the bit fields.

Address: Base address + 1Ch offset

**SIMx\_CLK\_PRESCALER field descriptions**

Field	Description
31–8 -	This field is reserved. Reserved
CLK_ PRESCALER	<b>Clock prescaler divisor register.</b> The value written to this register will determine the first stage divider setting. If the ipg_perclk is 66Mhz, a typical setting would be 0x0e. This would set the SIM card clock to 66Mhz/14 = 4.7Mhz. The duty cycle of divided clock will be between 45% and 55% according to ISO7816 requirement. For the odd divider factor (2K+1), the duty cycle will be K/(2K+1) and (K+1)/(2k+1). So for 0x03, the duty cycle is 33%-66%. For 0x05, the duty cycle is 40%-60%. For 0x07, the duty cycle is 43%-57%, and for 0x09, the duty cycle is 44%-56%. For all other values, the clock duty cycle can meet the ISO7816 requirement.  <b>NOTE:</b> Not all values are listed  0x00 ~0x02 ipg_perclk / 2 0x03 ipg_perclk / 3 0x04 ipg_perclk / 4 0x05 ipg_perclk / 5 0x06 ipg_perclk / 6 0xFD ipg_perclk / 253

Table continues on the next page...

## SIMx\_CLK\_PRESCALER field descriptions (continued)

Field	Description
0xFE	ipg_perclk / 254
0xFF	ipg_perclk / 255

## 11.2.5.9 SIM Receive Threshold Register (SIMx\_RCV\_THRESHOLD)

See the figure below for illustration of valid bits in the SIM Receive Threshold Register and the table below for description of the bit fields.

Address: Base address + 20h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved																RTH[3:0]			RDT[8:0]												
W	Reserved																RTH[3:0]			RDT[8:0]												
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

## SIMx\_RCV\_THRESHOLD field descriptions

Field	Description
31–13 -	This field is reserved. Reserved
12–9 RTH[3:0]	<b>Receive Nack Threshold.</b> Used to specify the number of consecutive NACK's transmitted by the SIM module, for a given character, before the receive threshold error (RTE) flag is triggered. A value of 0 indicates that RTE is never set. When a valid character is received by the SIM, the internal counter keeping track of the NACK count resets to zero for the subsequent byte being received. If the ANACK bit is clear in the CNTL register, RTH has no effect.
RDT[8:0]	<b>Receive Data Threshold.</b> Determines the number of unread bytes that must exist in the FIFO to trigger the receive data register full (RDRF) interrupt flag. If the number of unread bytes in the receive FIFO is greater than or equal to the value in RDT, the RDRF flag in the RCV_STATUS register will be set. A value of zero indicates that there must be 288 unread bytes in the FIFO to trigger RDRF. If a value of more than 288 is entered in this register, the register value will remain 288.

### 11.2.5.10 SIM Enable Register (SIMx\_ENABLE)

See the figure below for illustration of valid bits in the SIM Enable Register and the table below for description of the bit fields.

Address: Base address + 24h offset

#### SIMx\_ENABLE field descriptions

Field	Description
31–8 -	This field is reserved. Reserved
7 RXCL	Reception data latch disable. Used to disable/enable the cross clock domain synchronization operation of reception data in SIM receive state machine.  0 Enable the synchronization operation. 1 Disable the synchronization operation.
6 ESTOP_EXE	Enforce reception early stop execution. Used to execute the function of enforce reception early stop when ESTOP_EN bit set to 1. If this bit is 0 the early stop function can't be executed when NACK signal occur.  0 Enforce reception early stop function will be executed without NACK. 1 Enforce reception early stop function will be executed at all times.
5 ESTOP_EN	Enforce reception early stop enable. Used to early stop the SIM receive state machine. The state machine will stop earliey than 10.8 ETUs when 11 ETUs mode or earlier than 11.8 ETUs when non 11 ETUs mode, if enable this bit. This function is used for the test case transmission stop at 10.8 ETUs from the falling edge of start signal.  <b>NOTE:</b> This bit should be set to 1 when receive data, and set to 0 when transmit data.  0 Disable the enforce reception early stop function. 1 Enable the enforce reception early stop function.
4 NACK_DD_EN	NACK delay detection enable. Used to enable/disable the function of NACK delay detection. The SIM receive state machine will detect the NACK signal at the 16th phase and use the values of 12th, 14th and

Table continues on the next page...

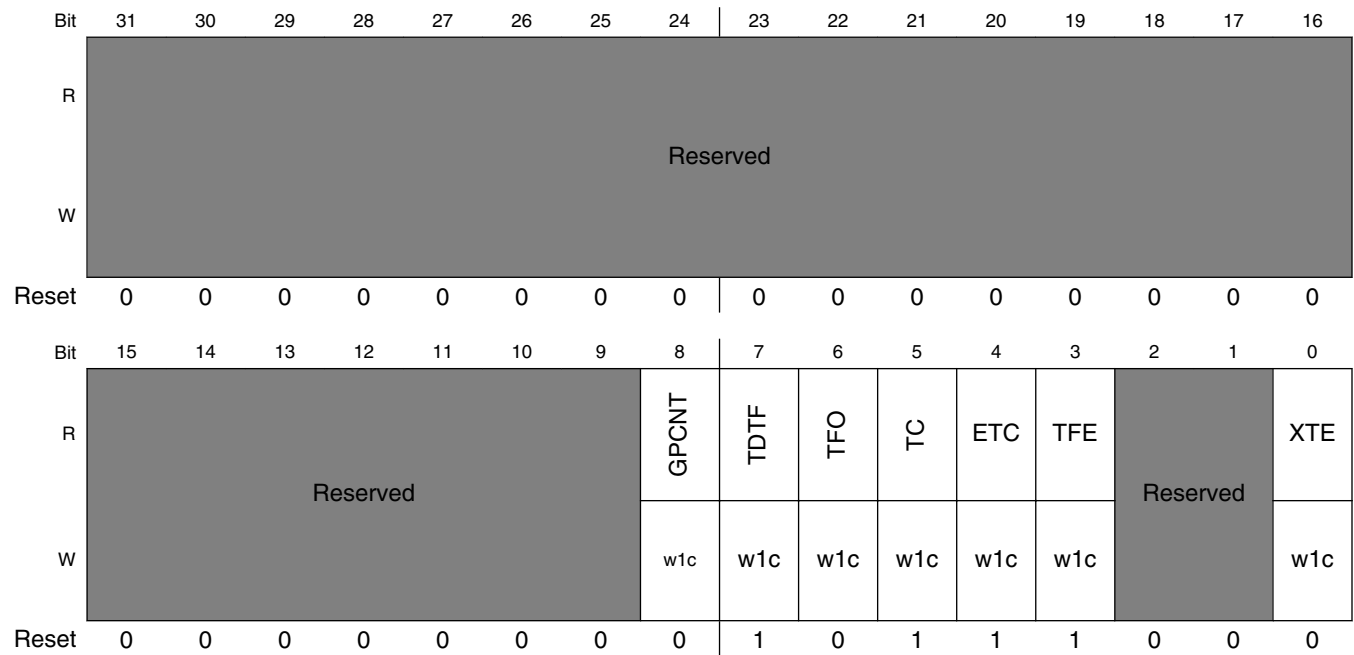

## SIMx\_ENABLE field descriptions (continued)

Field	Description
	<p>15th sample point, if enable this bit. This function is used for the test case NACK signal send at 10.7 ETUs from the falling edge of start signal.</p> <p>0 Disable the delay detection function. 1 Enable the delay detection function.</p>
3 TXDMA_EN	<p>Transmitter DMA Enable. This bit allows SIM to request for DMA transfers. When enabled, DMA requests are generated when the number of bytes in the transmit FIFO is less than or equal to the value programmed in the tdt[3:0] bits in the XMT_THRESHOLD register and XMT_EN is set.</p> <p>0 SIM Transmitter DMA requests disabled. 1 SIM Transmitter DMA requests enabled.</p>
2 RXDMA_EN	<p>Receiver DMA Enable. This bit allows SIM to request for DMA transfers. When enabled, DMA requests are generated when the number of bytes in the receive FIFO is more than or equal to the value programmed in the RDT[8:0] in the RCV_THRESHOLD register and RCV_EN is set</p> <p>0 SIM Receiver DMA request disabled. 1 SIM Receiver DMA request enabled.</p>
1 XMT_EN	<p><b>SIM Transmit Enable.</b> Used to enable/disable the SIM transmit state machine. When the SIM is being used to receive data, XMT_EN should be deasserted. This bit also enables the xmt_clk and rcv_clk inputs to the General Purpose Counter.</p> <p><b>NOTE:</b> Setting this bit (transition from 0 to 1) will reset the CRC and LRC values.</p> <p>0 SIM Transmitter disabled (default) 1 SIM Transmitter enabled</p>
0 RCV_EN	<p><b>SIM Receiver Enable.</b> Used to enable/disable the SIM receive state machine. The RCV_EN bit should be left high whenever the SIM module is in use. The SIM module has an automatic receive mode operation that disables the reception of characters when the transmitter is operational. Once the transmitter has completed sending the last character, the receiver is automatically enabled. This bit also enables the RCV_CLK input to the General Purpose Counter.</p> <p>0 SIM Receiver disabled (default) 1 SIM Receiver enabled</p>

### 11.2.5.11 SIM Transmit Status Register (SIMx\_XMT\_STATUS)

See the figure below for illustration of valid bits in the SIM Transmit Status Register and the table below for description of the bit fields.

Address: Base address + 28h offset

**SIMx\_XMT\_STATUS field descriptions**

Field	Description
31–9 -	This field is reserved. Reserved
8 GPCNT	<b>General purpose Counter Flag.</b> Used to indicate when the General purpose counter has reached the value in the GPCNT register.  0 GPCNT time not reached, or bit has been cleared. (default). 1 General Purpose counter has reached the GPCNT value.
7 TDTF	<b>Transmit Data Threshold Flag.</b> Used to indicate when the number of bytes in the transmit FIFO is less than or equal to the value programmed in the tdt[3:0] bits in the XMT_THRESHOLD register.  0 Number of bytes in FIFO is greater than tdt[3:0], or bit has been cleared. 1 Number of bytes in FIFO is less than or equal to tdt[3:0] (default)
6 TFO	<b>Transmit FIFO Overfill Error.</b> Used to indicate when the Transmit FIFO has been written with more than 16 bytes. The tfo bit can only be cleared by setting the flush_xmt or soft_reset bit in the RESET_CNTL register.  0 No transmit FIFO overfill error has occurred (default). 1 A Transmit FIFO overfill error has occurred.

Table continues on the next page...

## SIMx\_XMT\_STATUS field descriptions (continued)

Field	Description
5 TC	<p><b>Transmit Complete.</b> Used to indicate whether the SIM transmitter is ready for a new transmission. The tc flag becomes set after the guard time has expired for the last byte in the transmit FIFO. The tc flag will create an interrupt if tcim in the INT_MASK register is low. The tc bit is a write-one-to-clear bit.</p> <p>0 Transmit pending or in progress 1 Transmit complete (default)</p>
4 ETC	<p><b>Early Transmit Complete.</b> Used to indicate that the SIM transmitter has finished sending the current byte and the transmit FIFO is empty. This bit differs from the tc bit in that it is set before the guard time of the last byte has elapsed. The ETC flag will create an interrupt if ETCIM in the INT_MASK register is low. The ETC bit is a write-one-to-clear bit.</p> <p>0 Transmit pending or in progress 1 Transmit complete (default)</p>
3 TFE	<p><b>Transmit FIFO Empty.</b> Used to indicate that the SIM transmit FIFO has emptied. This bit will be set when the last byte in the transmit FIFO has been transferred to the SIM transmitter shift register. The TFE flag will create an interrupt if TFEIM in the INT_MASK register is low. The TFE bit is a write-one-to-clear bit.</p> <p>0 Transmit FIFO is not empty 1 Transmit FIFO is empty (default)</p>
2-1 -	<p>This field is reserved. Reserved</p>
0 XTE	<p><b>Transmit NACK Threshold Error.</b> Used to indicate the transmit NACK threshold has been reached. When XTE is high, no further transmissions will be done until the XTE flag is cleared. Any data transmissions still pending in the transmit FIFO will be aborted, and the TC, ETC, and TFE flags will be set. The XTE flag will create an interrupt if XTM in the INT_MASK register is low. The XTE bit is a write-one-to-clear bit.</p> <p>0 Transmit NACK threshold has not been reached (default) 1 Transmit NACK threshold reached; transmitter frozen</p>

### 11.2.5.12 SIM Receive Status Register (SIMx\_RCV\_STATUS)

See the figure below for illustration of valid bits in the SIM Receive Status Register and the table below for description of the bit fields.

Address: Base address + 2Ch offset

**SIMx\_RCV\_STATUS field descriptions**

Field	Description
31–12 -	This field is reserved. Reserved
11 BGT	<b>Block guard time error flag.</b> Used to indicate if the block guard time was too small. The threshold is set by the block guard time register.  0 Block guard time was sufficient. 1 Block guard time was too small.
10 BWT	<b>Block wait time error flag.</b> Used to indicate if the block wait time has been exceeded. The threshold is set by the block wait time registers.  0 Block wait time not exceeded. 1 Block wait time was exceeded.
9 RTE	<b>Receive NACK threshold error flag.</b> Used to indicate whether the number of consecutive NACKs generated by the SIM module in response to receive parity errors, for the byte being received, equals the

Table continues on the next page...

## SIMx\_RCV\_STATUS field descriptions (continued)

Field	Description
	<p>value programmed in the RTH[3:0] in the RCV_THRESHOLD register. This bit would never be set unless the ANACK bit is set in the CNTL register. The SAPDx bit in the PORTx_CNTL register must be set to enable the threshold error to trigger the auto power down sequence. RTE is a write-one-to-clear bit. Clearing this bit also resets the internal counter for consecutive NACKs being transmitted for a given byte.</p> <p>0 Number of NACKs generated by the receiver is less than the value programmed in RTH[3:0]  1 Number of NACKs generated by the receiver is equal to the value programmed in RTH[3:0]</p>
8 CWT	<p><b>Character Wait Time Counter Flag.</b> Used to indicate when the time between received characters is equal to or greater than the value programmed in the CHAR_WAIT register.</p> <p>0 No CWT violation has occurred (default).  1 Time between two consecutive characters exceeded the value in CHAR_WAIT.</p>
7 CRCOK	<p><b>Cyclic Redundancy Check Okay flag.</b> Used to indicate when the calculated 16-bit CRC value matches the expected value for the current input data stream. The value is calculated across all received characters from the point the CRCEN bit is set in the CNTL register. The current CRC residual can be reset by three mechanisms:</p> <p>Clear CRCEN bit in CNTL register  Set XMT_EN bit in ENABLE register  Automatically by hardware when ETC flag is set at the end of a transmission.</p> <p>0 Current CRC value does not match remainder.  1 Current calculated CRC value matches the expected result.</p>
6 LRCOK	<p>Linear Redundancy Check Okay flag. Used to indicate when the calculated 8-bit LRC value is zero value for the current input data stream. The value is calculated across all received characters from the point the LRCEN bit is set in the CNTL register. The current LRC residual can be reset by three mechanisms:</p> <p>Clear LRCEN bit in CNTL register  Set XMT_EN bit in ENABLE register  Automatically by hardware when ETC flag is set at the end of a transmission.</p> <p>0 Current LRC value does not match remainder.  1 Current calculated LRC value matches the expected result (that is, zero).</p>
5 RDRF	<p>Receive Data Register Full. Used to indicate when the number of bytes in the receive FIFO is more than or equal to the value programmed in the RDT[8:0] in the RCV_THRESHOLD register.</p> <p>0 Number of unread bytes in receive buffer &lt; value set by RDT[8:0] (default), or bit has been cleared.  1 Number of unread bytes in receive buffer &gt;= value set by RDT[8:0].</p>
4 RFD	<p><b>Receive FIFO has unread Data.</b> Used to indicate that there is at least one unread byte in the receive data FIFO. Can only be cleared by reading all bytes out of the receive FIFO. The RFD bit cannot be used to create an interrupt. Normally, the SIM triggers the interrupt with RDRF and software uses rfd to read all of the bytes out of the receive FIFO.</p> <p>0 There are no unread bytes in the receive FIFO (default).  1 There is at least one unread byte in the receiver FIFO.</p>
3–2 -	<p>This field is reserved.  Reserved</p>
1 RFE	<p><b>Receive FIFO Empty.</b> Used to indicate that the SIM receive FIFO has emptied. This bit will be set when the last byte in the receive FIFO has been transferred to the IPS bus. The RFE flag will create an interrupt if RFEIM in the INT_MASK register is low. The RFE bit is a write-one-to-clear bit.</p>

Table continues on the next page...

**SIMx\_RCV\_STATUS field descriptions (continued)**

Field	Description
	0 Receive FIFO is not empty 1 Receive FIFO is empty (default)
0 OEF	<b>Overflow Error Flag.</b> Used to indicate that the SIM was unable to store received data due to already having 288 unread bytes in the FIFO. It does not necessarily indicate that data has been lost. If the ONACK control bit in the CNTL register is set, there will be a NACK pulse generated on bytes that would otherwise cause a loss of data due to a full FIFO. These bytes should be retransmitted by the SIM card which implies that no data has actually been lost. In this case, the OEF flag is just an indicator that this situation has occurred which may be helpful in system debug. For the case where ONACK is not set, a set OEF flag does indicate a loss of data since all bytes received with the OEF flag set will indeed be lost (including the byte that caused the bit to be set). The OEF flag will cause an interrupt if the oim bit in the INT_MASK register. The OEF flag is a write-one-to-clear bit.  0 No overrun error has occurred (default). 1 A byte was received when the received FIFO was already full.

**11.2.5.13 SIM Interrupt Mask Register (SIMx\_INT\_MASK)**

See the figure below for illustration of valid bits in the SIM Interrupt Mask Register and the table below for description of the bit fields.

Address: Base address + 30h offset

**SIMx\_INT\_MASK field descriptions**

Field	Description
31–14 -	This field is reserved. Reserved
13 RFEM	<b>Receive fifo empty interrupt mask.</b> Used to enable/disable the ability of the RFE flag in the RCV_STATUS register to generate SIM interrupts.

*Table continues on the next page...*

## SIMx\_INT\_MASK field descriptions (continued)

Field	Description
	0 RFE interrupt enabled 1 RFE interrupt masked (default)
12 BGTM	<b>Block guard time interrupt mask.</b> Used to enable/disable the ability of the bgt flag in the RCV_STATUS register to generate SIM interrupts.  0 BGT interrupt enabled 1 BGT interrupt masked (default)
11 BWTM	<b>Block wait time interrupt mask.</b> Used to enable/disable the ability of the bwt flag in the RCV_STATUS register to generate SIM interrupts.  0 BWT interrupt enabled 1 BWT interrupt masked (default)
10 RTM	<b>Receive Nack threshold interrupt mask.</b> Used to enable/disable the ability of the RTE flag in the RCV_STATUS register to generate SIM interrupts.  0 RTE interrupt enabled 1 RTE interrupt masked (default)
9 CWTM	<b>Character Wait Time Interrupt Mask.</b> Used to enable/disable the ability of the CWT flag in the RCV_STATUS register to generate SIM interrupts.  0 CWT interrupt enabled 1 CWT interrupt masked (default)
8 GPCNTM	<b>General Purpose Counter Interrupt Mask.</b> Used to enable/disable the ability of the GPCNT flag in the XMT_STATUS register to generate SIM interrupts.  0 GPCNT interrupt enabled 1 GPCNT interrupt masked (default)
7 TDTFM	<b>Transmit Data Threshold Interrupt Mask.</b> Used to enable/disable the ability of the TDTF flag in the XMT_STATUS register to generate SIM interrupts.  0 TDTF interrupt enabled 1 TDTF interrupt masked (default)
6 TFOM	<b>Transmit FIFO Overfill Error Interrupt Mask.</b> Used to enable/disable the ability of the TFO flag in the XMT_STATUS register to generate SIM interrupts.  0 TFO interrupt enabled 1 TFO interrupt masked (default)
5 XTM	<b>Transmit Threshold Interrupt Mask.</b> Used to enable/disable the ability of the XTE flag in the XMT_STATUS register to generate SIM interrupts  0 XTE interrupt enabled 1 XTE interrupt masked (default)
4 TFEIM	<b>Transmit FIFO Empty Interrupt Mask.</b> Used to enable/disable the ability of the TFE flag in the XMT_STATUS register to generate SIM interrupts.  0 TFE interrupt enabled 1 TFE interrupt masked (default)
3 ETCIM	<b>Early Transmit Complete Interrupt Mask.</b> Used to enable/disable the ability of the ETC flag in the XMT_STATUS register to generate SIM interrupts.

*Table continues on the next page...*

**SIMx\_INT\_MASK field descriptions (continued)**

Field	Description
	0 ETC interrupt enabled 1 ETC interrupt masked (default)
2 OIM	<b>Overrun Interrupt Mask.</b> Used to enable/disable the ability of the OEF flag in the RCV_STATUS register to generate SIM interrupts.  0 OEF interrupt enabled 1 OEF interrupt masked (default)
1 TCIM	<b>Transmit Complete Interrupt Mask.</b> Used to enable/disable the ability of the TC flag in the XMT_STATUS register to generate SIM interrupts.  0 TC interrupt enabled 1 TC interrupt masked (default)
0 RIM	<b>Receive Interrupt Mask.</b> Used to enable/disable the ability of the RDRF flag in the RCV_STATUS register to generate SIM interrupts.  0 RDRF interrupt enabled 1 RDRF interrupt masked (default)

**11.2.5.14 SIM Port0 Detect Register (SIMx\_PORT0\_DETECT)**

See the figure below for illustration of valid bits in the SIM Port0 Detect Register and the table below for description of the bit fields.

SPDS0 determines which edge transition of the SIMPD0 pin is used for SIM card presence detection. Presence detection can be used to determine if the card has been inserted or removed. The occurrence of the SIMPD0 edge, specified by SPDS0, will cause the following:

- SDI0 to be set
- If the SDIM0 mask is clear, an interrupt to occur on SIMIRQ\_N
- If SAPD0 in the PORT0\_CNTL register is set, auto power down sequence will begin

If a SIM card insertion is expected, SAPD0 can be set low to avoid the auto power down sequence. There is no auto power up sequence. SPDP0 can be used to determine the current state of the SIMPD0 pin.

Address: Base address + 3Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	Reserved												SPDS0	SPDP0	SDI0	SDIM0
W															w1c	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

**SIMx\_PORT0\_DETECT field descriptions**

Field	Description
31–4 -	This field is reserved. Reserved
3 SPDS0	<b>SIM Presence Detect Select Port 0.</b> Controls which edge of the SIMPD0 pin is used to detect the presence of the SIM card.  0 Falling edge of SIMPD0 Input (default) 1 Rising edge of SIMPD0 Input
2 SPDP0	<b>SIMPDP0 input pin status.</b> This bit reflects the state of the SIMPD0 pin. It is not a latched register bit, but instead a synchronized version of the state of the SIMPD0 pin itself.  0 SIMPD0 pin is logic low 1 SIMPD0 pin is logic high
1 SDI0	<b>SIM Detect Interrupt flag Port 0.</b> Status flag to indicate the insertion or removal of a SIM card has been detected on port 0. Can create an interrupt to the MCU if SDIM0 is low. Write a "1" to this bit to clear.  0 No insertion or removal of SIM card detected on Port 0 (default) 1 Insertion or removal of SIM card detected on Port 0
0 SDIM0	<b>SIM Detect Interrupt Mask Port 0.</b> Interrupt mask for the SDI0 interrupt flag.  0 sdi0 enabled 1 sdi0 masked (default)

### 11.2.5.15 SIM Data Format Register (SIMx\_DATA\_FORMAT)

See the figure below for illustration of valid bits in the SIM Data Format Register and the table below for description of the bit fields.

Address: Base address + 40h offset

**SIMx\_DATA\_FORMAT field descriptions**

Field	Description
31–1 -	This field is reserved. Reserved
0 IC	<b>Inverse Convention.</b> Used to configure the SIM to use either inverse convention or direct convention for its data format. The IC bit can be controlled by software, but it is normally set by hardware as a result of the interpretation of the initial character when in ICM mode.  0 Direction convention transfers enabled (default). 1 Inverse convention transfers enabled.

### 11.2.5.16 SIM Transmit Threshold Register (SIMx\_XMT\_THRESHOLD)

See the figure below for illustration of valid bits in the SIM Transmit Threshold Register and the table below for description of the bit fields.

Address: Base address + 44h offset

**SIMx\_XMT\_THRESHOLD field descriptions**

Field	Description
31–8 -	This field is reserved. Reserved

*Table continues on the next page...*

**SIMx\_XMT\_THRESHOLD field descriptions (continued)**

Field	Description
7-4 XTH	<p><b>XTH[3:0] Transmit NACK Threshold.</b> Used to set the NACK threshold for the transmitter. Once the threshold number set by XTH has been reached for the current byte being transmitted, the error flag XTE in the XMT_STATUS register will be set. Setting of XTE causes the remaining transmissions queued in the transmit FIFO to be aborted and no more transmissions to occur until software clears XTE. To trigger XTE, a given byte being transmitted must reach the XTH threshold itself. Transmit NACKs accumulated on one byte are not carried over to the next.</p> <p>0x0 XTE will never be set; retransmission after NACK reception is disabled.  0x1 XTE will be set after 1 nack is received; 0 retransmissions occurs.  0x2 XTE will be set after 2 nacks are received; at most 1 retransmission occurs.  0x3 XTE will be set after 3 nacks are received; at most 2 retransmissions occurs.  0xX XTE will be set after X nacks are received; at most (X - 1) retransmissions occurs.  0xF XTE will be set after 15 nacks are received; at most 14 retransmissions occurs.</p>
TDT	<p><b>Transmit Data Threshold.</b> Used to set the threshold value for the Transmit FIFO at which the TDTF bit in the XMT_STATUS register will be set. When the number of bytes in the Transmit FIFO is less than or equal to TDT[3:0], TDTF will be set.</p>

**11.2.5.17 SIM Transmit Guard Control Register (SIMx\_GUARD\_CNTL)**

See the figure below for illustration of valid bits in the SIM Transmit Guard Control Register and the table below for description of the bit fields.

Address: Base address + 48h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**SIMx\_GUARD\_CNTL field descriptions**

Field	Description
31-9 -	This field is reserved. Reserved

Table continues on the next page...

**SIMx\_GUARD\_CNTL field descriptions (continued)**

Field	Description
8 RCVR11	<p><b>Receiver use 11 ETUs.</b> Used to configure the SIM module receiver for 11 ETU operation (that is, 1 Stop bit). This bit is provided for support of T=1 cards.</p> <p>0 Receiver configured for 12 ETU operation (default)                      1 Receiver configured for 11 ETU operation</p>
GETU	<p><b>Transmit Guard ETUs.</b> Used to control the number of additional Elementary Time Units (ETUs) inserted between bytes transmitted by the SIM transmitter. An ETU is equivalent to one bit time at the given baud rate (for example, the length of a START bit). The guard time has no effect on the SIM receiver. A value of 0x00 inserts no additional ETUs, while a value of 0xFE inserts 254 additional ETUs. A value of 0xFF subtracts one ETU by reducing the number of STOP bits from two to one.</p>

**11.2.5.18 SIM Open Drain Configuration Control Register (SIMx\_OD\_CONFIG)**

See the figure below for illustration of valid bits in the SIM Open Drain Configuration Control Register and the table below for description of the bit fields.

Address: Base address + 4Ch offset

**SIMx\_OD\_CONFIG field descriptions**

Field	Description
31–2 -	This field is reserved. Reserved
1 OD_P1	<p><b>Open Drain control for Port 1.</b> Used to control whether the XMT data line on port 1 is open-drain. If AMODE bit in SETUP register is set, this bit will have no effect.</p> <p>0 XMT pin on port 1 is push-pull (default).                      1 XMT pin on port 1 is open-drain.</p>

Table continues on the next page...

## SIMx\_OD\_CONFIG field descriptions (continued)

Field	Description
0 OD_P0	<b>Open Drain control for Port 0.</b> Used to control whether the XMT data line on port 0 is open-drain. 0 XMT pin on port 0 is push-pull (default). 1 XMT pin on port 0 is open-drain.

## 11.2.5.19 SIM Reset Control Register (SIMx\_RESET\_CNTL)

See the figure below for illustration of valid bits in the SIM Reset Control Register and the table below for description of the bit fields.

Address: Base address + 50h offset

## SIMx\_RESET\_CNTL field descriptions

Field	Description
31–6 -	This field is reserved. Reserved

Table continues on the next page...

## SIMx\_RESET\_CNTL field descriptions (continued)

Field	Description
5 STOP	<p><b>STOP.</b> Used to configure the operation of the SIM module when a processor STOP instruction is executed. This bit is added to provide support for SIM cards that do not allow the SIM Card clock to be stopped while power is applied.</p> <p>0 STOP instruction shuts down all SIM clocks (default). 1 STOP instruction shuts down all clocks except for the BAUD_CLK (clock provided to SIM Card).</p>
4 DOZE	<p><b>DOZE.</b> Used to configure the operation of the SIM module when a processor DOZE instruction is executed.</p> <p>0 DOZE instruction has no effect on SIM module (default). 1 DOZE instruction will cause SIM module to gate SIM clocks when the transmit FIFO is empty.</p>
3 KILL_CLOCK	<p><b>Kill SIM Clock.</b> Used to enable/disable the SIM clock input to the SIM module. This bit will gate all SIM clocks including the SIM card clock regardless of the state of the STOP bit described above.</p> <p>0 SIM input clock enabled (default). 1 SIM input clock disabled.</p>
2 SOFT_RST	<p><b>Software Reset.</b> Used to reset the entire SIM module. This acts the same as a hardware reset for the SIM module. This bit is self-clearing.</p> <p><b>NOTE:</b> Software should allow a minimum of 4 reference clock cycles (CKIH) before attempting to access the SIM module after a software reset.</p> <p>0 SIM Normal operation (default). 1 SIM held in Reset.</p>
1 FLUSH_XMT	<p><b>Flush Transmitter.</b> This bit operates as a SIM transmitter reset. The receive portion of the SIM module is not affected. The software must clear this bit before the SIM transmitter can operate.</p> <p>0 SIM Transmitter normal operation (default). 1 SIM Transmitter held in Reset.</p>
0 FLUSH_RCV	<p><b>Flush Receiver.</b> This bit operates as a SIM receiver reset. The transmit portion of the SIM module is not affected. The software must clear this bit before the SIM receiver can operate.</p> <p>0 SIM Receiver normal operation (default). 1 SIM Receiver held in Reset.</p>

## 11.2.5.20 SIM Character Wait Time Register (SIMx\_CHAR\_WAIT)

See the figure below for illustration of valid bits in the SIM Character Wait Time Register and the table below for description of the bit fields.

Address: Base address + 54h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																																
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	

## SIMx\_CHAR\_WAIT field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
CWT	<b>Character Wait Time.</b> The value written to this register will specify the number of ETU times allowed between characters.  Default is 0xFFFF

## 11.2.5.21 SIM General Purpose Counter Register (SIMx\_GPCNT)

See the figure below for illustration of valid bits in the SIM General Purpose Counter Register and the table below for description of the bit fields.

Address: Base address + 58h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved																GPCNT															
W	Reserved																GPCNT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

## SIMx\_GPCNT field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
GPCNT	<b>General Purpose Counter.</b> The value written to this register will be used to compare to the general purpose counter in the SIM module. Once the General purpose counter reaches this value, the GPCNT flag in the XMT_STATUS register will be set.  This counter is intended to be used for any events that must be monitored for duration based on the card clock, receiver sample rate, or ETU rate (transmit clock). Example: ATR arrival time and ATR duration.  Default is 0xFFFF

## 11.2.5.22 SIM Divisor Register (SIMx\_DIVISOR)

See the figure below for illustration of valid bits in the SIM Divisor Register and the table below for description of the bit fields.

Address: Base address + 5Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved																DIVISOR															
W	Reserved																DIVISOR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1

### SIMx\_DIVISOR field descriptions

Field	Description
31–8 -	This field is reserved. Reserved
DIVISOR	<b>DIVISOR Register.</b> The value written to this register will be used to generate the SIM Receive clock. The BAUD_SEL[2:0] bits in the CNTL register must be set to '111' in order to control the divisor value using the DIVISOR register.  Default is 0xFF

### 11.2.5.23 SIM Block Wait Time Register (SIMx\_BWT)

See the figure below for illustration of valid bits in the SIM Block Wait Time Register and the table below for description of the bit fields.

Address: Base address + 60h offset

### SIMx\_BWT field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
BWT	<b>BWT Register 16 LSB.</b> The value in this register is the block wait time 16 LSB. The time from START bit of last byte sent from the SIM module to the START bit of the first byte sent from the SmartCard must be less than the value formed by the 32-bit register composed by BWT_H and BWT registers. If it is not, then the BWT flag will be set.  Default is 0xFFFF

### 11.2.5.24 SIM Block Guard Time Register (SIMx\_BGT)

See the figure below for illustration of valid bits in the SIM Block Guard Time Register and the table below for description of the bit fields.

Address: Base address + 64h offset

## SIMx\_BGT field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
BGT	<b>BGT Register.</b> The value in this register is the block guard time. Time from START bit of last byte sent from the SIM module to the START bit of the first byte sent from the SmartCard must be greater than this value. If it is not, then the BGT flag will be set.  Default is 0x0000

## 11.2.5.25 SIM Block Wait Time Register HIGH (SIMx\_BWT\_H)

See the figure below for illustration of valid bits in the SIM Block Wait Time Register HIGH and the table below for description of the bit fields.

Address: Base address + 68h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved																BWT_H															
W	Reserved																BWT_H															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

## SIMx\_BWT\_H field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
BWT_H	<b>BWT Register 16 MSB.</b> The value in this register is the block wait time 16 MSB. The time from START bit of last byte sent from the SIM module to the START bit of the first byte sent from the SmartCard must be less than the value formed by the 32-bit register composed by BWT_H and BWT registers. If it is not, then the BWT flag is set.  Default is 0xFFFF

## 11.2.5.26 SIM Transmit FIFO Status Register (SIMx\_XMT\_FIFO\_STAT)

See the figure below for illustration of valid bits in the SIM Transmit FIFO Status Register and the table below for description of the bit fields.

Address: Base address + 6Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved																XMT_CNT				XMT_WPTR				XMT_RPTR							
W	Reserved																XMT_CNT				XMT_WPTR				XMT_RPTR							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**SIMx\_XMT\_FIFO\_STAT field descriptions**

Field	Description
31-12 -	This field is reserved. Reserved
11-8 XMT_CNT	These bits indicate the number of Bytes in the transmit FIFO. '0' value means FIFO is empty or full.
7-4 XMT_WPTR	These bits indicate the transmit FIFO Write Pointer.
XMT_RPTR	These bits indicate the transmit FIFO Read Pointer.

**11.2.5.27 SIM Receive FIFO Counter Register (SIMx\_RCV\_FIFO\_CNT)**

See the figure below for illustration of valid bits in the SIM Receiver FIFO Counter Register and the table below for description of the bit fields.

Address: Base address + 70h offset

**SIMx\_RCV\_FIFO\_CNT field descriptions**

Field	Description
31-9 -	This field is reserved. Reserved
RCV_CNT	These bits indicate the number of Byte can be written into the receive FIFO. 0 value means FIFO is empty or full.

### 11.2.5.28 SIM Receive FIFO Write Pointer Register (SIMx\_RCV\_FIFO\_WPTR)

See the figure below for illustration of valid bits in the SIM Receive FIFO Write Pointer Register and the table below for description of the bit fields.

Address: Base address + 74h offset

**SIMx\_RCV\_FIFO\_WPTR field descriptions**

Field	Description
31–9 -	This field is reserved. Reserved
RCV_WPTR	These bits indicate the receive FIFO Write pointer.

### 11.2.5.29 SIM Receive FIFO Read Pointer Register (SIMx\_RCV\_FIFO\_RPTR)

See the figure below for illustration of valid bits in the SIM Receive FIFO Read Pointer Register and the table below for description of the bit fields.

Address: Base address + 78h offset

**SIMx\_RCV\_FIFO\_RPTR field descriptions**

Field	Description
31–9 -	This field is reserved. Reserved
RCV_RPTR	These bits indicate the receiver FIFO read pointer.

## 11.3 PCI Express PHY (PCle\_PHY)

### 11.3.1 Overview

This block provides information regarding PCIe PHY and its features. PCIe PHY supports 6.0 Gbps data rate and complies to PCI Express base specification 2.1. The functions that are performed by the transceiver include serializing the 8B/10B encoded data for transmission, de-serializing received code groups, and word alignment.

When transmitting, the transceiver accepts two or four 10-bit 8B/10B encoded transmit characters, latches them and serializes the data onto the PCIE\_TX\_P/PCIE\_TX\_N differential outputs at 1.5 / 2.5 / 3.0 / 5.0 / 6.0 Gbps. It also performs 8B/10B encoding for 8-bit data from the PIPE interface.

When receiving, the transceiver also samples received serial data on the PCIE\_RX\_P / PCIE\_RX\_N differential inputs, deserializes it into two or four 10-bit received characters and detects the K28.5 character (0011111010 or 1100000101) for word alignment. It also applies 8B/10B decoding for 8-bit data to the PIPE interface. PCIe PHY core contains on-chip PLL circuitry for synthesis of the baud-rate transmitting clocks, and extraction of the retimed clocks from the received serial stream.

#### 11.3.1.1 Block Diagram

Figure 11-52. Block Diagram

### 11.3.1.2 Features

The following list the key features of the PCIe PHY:

- 1.5 / 2.5 / 3.0 / 5.0 / 6.0 Gbps Serializer / Deserializer
- Compliant with PCI Express Base Specification 2.1
- Compliant with PIPE Specification 2.0
- 8 / 16 / 20 / 40-bit CMOS Interface for Transmitter and Receiver
- 25 / 100 MHz Reference Clock
- K28.5 Detection for Word Alignment
- 8B/10B Encoding / Decoding
- Receiver Detection
- 28 nm CMOS Process (LN28LPP)
- Supports Spread Spectrum Clocking in Transmitter and Receiver

### 11.3.2 PCIe PHY Signals

#### 11.3.2.1 External Signal

The following table describes the external signals and power supplies to PCIe PHY.

**Table 11-54. External I/O and Power**

Signal	Description	Pad	Mode	Direction
PCIE_TX_P	Positive-side transmitted differential output from the PHY. Terminal transmit NRZ data rate of 1.5 - 6.0 Gbps.	PCIE_TX_P	Not multiplexed	O
PCIE_TX_N	Negative-side transmitted differential output from the PHY. Terminal transmit NRZ data rate of 1.5 - 6.0 Gbps.	PCIE_TX_N	Not multiplexed	O
PCIE_RX_P	Positive-side received differential input from the PHY. Terminal receive NRZ data rate of 1.5 - 6.0 Gbps.	PCIE_RX_P	Not multiplexed	I

*Table continues on the next page...*

**Table 11-54. External I/O and Power (continued)**

Signal	Description	Pad	Mode	Direction
PCIE_RX_N	Negative-side received differential input from the PHY. Terminal receive NRZ data rate of 1.5 - 6.0 Gbps.	PCIE_RX_N	Not multiplexed	I
PCIE_REXT	External reference resistor input.	PCIE_REXT	Not multiplexed	IO
PCIE_REFCLKOUT_P	100 MHz Positive-side Reference Clock Differential Output for PCIE.	PCIE_REFCLKOUT_P	Not multiplexed	O
PCIE_REFCLKOUT_N	100 MHz Negative-side Reference Clock Differential Output for PCIE.	PCIE_REFCLKOUT_N	Not multiplexed	O
PCIE_REFCLKIN_P	100 MHz Positive-side Reference Clock Differential Input for PCIE.	PCIE_REFCLKIN_P	Not multiplexed	I
PCIE_REFCLKIN_N	100 MHz Negative-side Reference Clock Differential Input for PCIE.	PCIE_REFCLKIN_N	Not multiplexed	I
PCIE_VP	1.0 V (or 1.1 V) Power for Common block of the PHY	PCIE_VP	Not multiplexed	Supply
PCIE_VPH	1.8 V Voltage Regulator / Bias Power for Common block of the PHY	PCIE_VPH	Not multiplexed	Supply
PCIE_VP_TX	1.0 V (or 1.1 V) Power for Transmitter block of the PHY	PCIE_VP_TX	Not multiplexed	Supply
PCIE_VPH_TX	1.8 V Voltage Regulator for Transmitter block of the PHY	PCIE_VPH_TX	Not multiplexed	Supply
PCIE_VP_RX	1.0 V (or 1.1 V) Power for Receiver block of the PHY	PCIE_VP_RX	Not multiplexed	Supply
PCIE_VPH_RX	1.8 V Voltage Regulator for Receiver block of the PHY	PCIE_VPH_RX	Not multiplexed	Supply
PCIE_GND	Ground for the PHY	PCIE_GND	Not multiplexed	Ground

### 11.3.2.2 Interface Signals

This section describes the interface signals to PCIe PHY.

**Table 11-55. Interface Signals Description**

Signal	Description
REF_CKO	Buffered Reference Clock Output. REF_CKO is 25 or 100 MHz according to the reference clock input frequency.
REFCLK_SEL	Internal Reference Clock Enable. When driven high, REFCLK_EXT is the reference clock of PHY.
REFCLK_EXT	Internal Reference Clock Input. REFCLK_EXT is the reference clock from logic. The nominal frequency is 25 / 100 MHz.
HIGH_SPEED	Maximum Speed Selection. When driven high, the maximum data rate is Gen2 PCIe. When driven low, the maximum data rate Gen1 PCIe.
TXD	<i>Transmit Data</i>
RXD	<i>Receive Data</i>
TBC	<i>PIPE Interface Input Data Clock</i> TBC is the transmit byte clock used to latch all input data on the PIPE interface. Transitions of TXD and other inputs occur at rising edge of TBC. TBC is 250 MHz both 2.5 Gbps and 5.0 Gbps, when HIGH_SPEED is high. TBC is required to be frequency locked to reference clock from PCIE_REFCLKIN_P/N or REFCLK_EXT. The exact timing relationship between TBC and reference clock is not tightly specified, however the TBC should be derived from the PC_CLK (PCLK) clock.
RBC	<i>Receive Byte Clock.</i> RBC is locked to the received data. RBC is 75 MHz at 1.5 Gbps, 150 MHz at 3.0 Gbps, and 300 MHz at 6.0 Gbps. The parallel output data are valid on the rising edge of RBC.
PC_CLK	<i>PIPE Interface Output Data Clock.</i> All output data movement across the parallel interface is synchronized to this clock. This clock operates at 250 MHz regardless of the Rate control input. The rising edge of the clock is the reference for all output signals. Spread spectrum modulation on this clock is allowed.

### 11.3.2.3 Reference Clock

Reference Clock input jitter should be tightly controlled to ensure very high-speed clock operation and its jitter characteristics. Jitter performance of the PCIe PHY is dependent on a low-jitter reference clock source. It can use Crystal Oscillator input, PCIE\_REFCLKIN\_P/N, or internal clock input, REFCLK\_EXT as a Reference Clock

input. For more detail, please refer to the datasheet. When the REFCLK\_EXT is used, the external IO pin of PCIE\_REFCLKIN\_P/N cannot be floating and proper powerdown control should be considered.

For the reference clock differential output for the PCIe PHY (PCIE\_REFCLKOUT\_P and PCIE\_REFCLKOUT\_N), the external resistors should be connected to ground in the PCB board. It is open drain structure.

### 11.3.3 Functional Description

#### 11.3.3.1 Common Block

Figure 11-53. Common Block Diagram

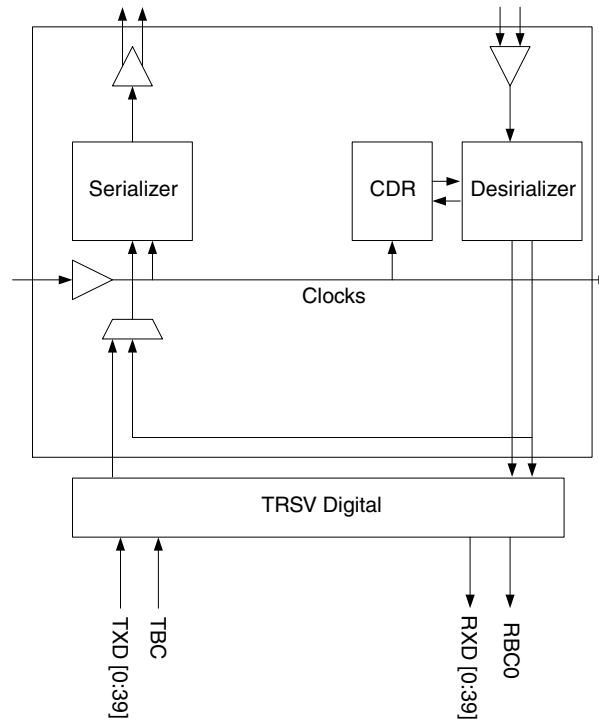

### 11.3.3.1.1 Phase Locked Loop (PLL)

In the PCIe PHY core, the PLL is locked at the multiple frequency of reference clock (PCIE\_REFCLKIN\_P/N) and generates all internal multi-phase clocks for transceiver. These clocks are based on the supplied PCIE\_REFCLKIN\_P/N.

### 11.3.3.2 Transceiver block

Figure 11-54. Transceiver Block Diagram

#### 11.3.3.2.1 Serializer

The PCIe PHY core accepts two or four 10-bit parallel characters from the link layer on the TXD[0:19] or TXD[0:39] bus which are latched into the input latch. This data will be serialized and transmitted on the PCIE\_TX\_P / PCIE\_TX\_N differential outputs at 1.5 / 3.0 / 6.0 Gbps, with bit TXD [0] transmitted first.

#### 11.3.3.2.2 Clock and Data Recovery (CDR)

The PCIe PHY core accepts high-speed differential serial inputs on the PCIE\_RX\_P / PCIE\_RX\_N pins, extracts the retimed clocks and recovers the data. The serial bit stream should be encoded so as to provide DC balance and limited run length using 8B/10B

encoding. The PCIe PHY core clock recovery circuitry is completely monolithic and requires no external components. For proper operation, the baud rate of the data stream to be recovered should meet the PCIe specification.

The retimed serial bit stream is converted into two or four 10-bit parallel output characters on the RXD[0:19] or RXD[0:39] of which the RXD[0] is received first. The PCIe PHY core provides retimed clock, RBC. The RBC is generated from one of the high-speed clocks which is phase locked to the reference clock. The serial data is retimed by the internal high-speed clocks, and deserialized.

Even if serial input data is not present, or does not meet the required baud rate, the PCIe PHY core will continue to produce retimed clock, RBC, which locks to the REF\_CK, reference clock.

### 11.3.3.2.3 Word Alignment

The PCIe PHY core provides K28.5 character recognition and data word alignment. When synchronization is enabled, the PCIe PHY core constantly examines the serial data for the presence of the K28.5 character (0011111010 / 1100000101).

**Figure 11-55. Detection of a K28.5 Character**

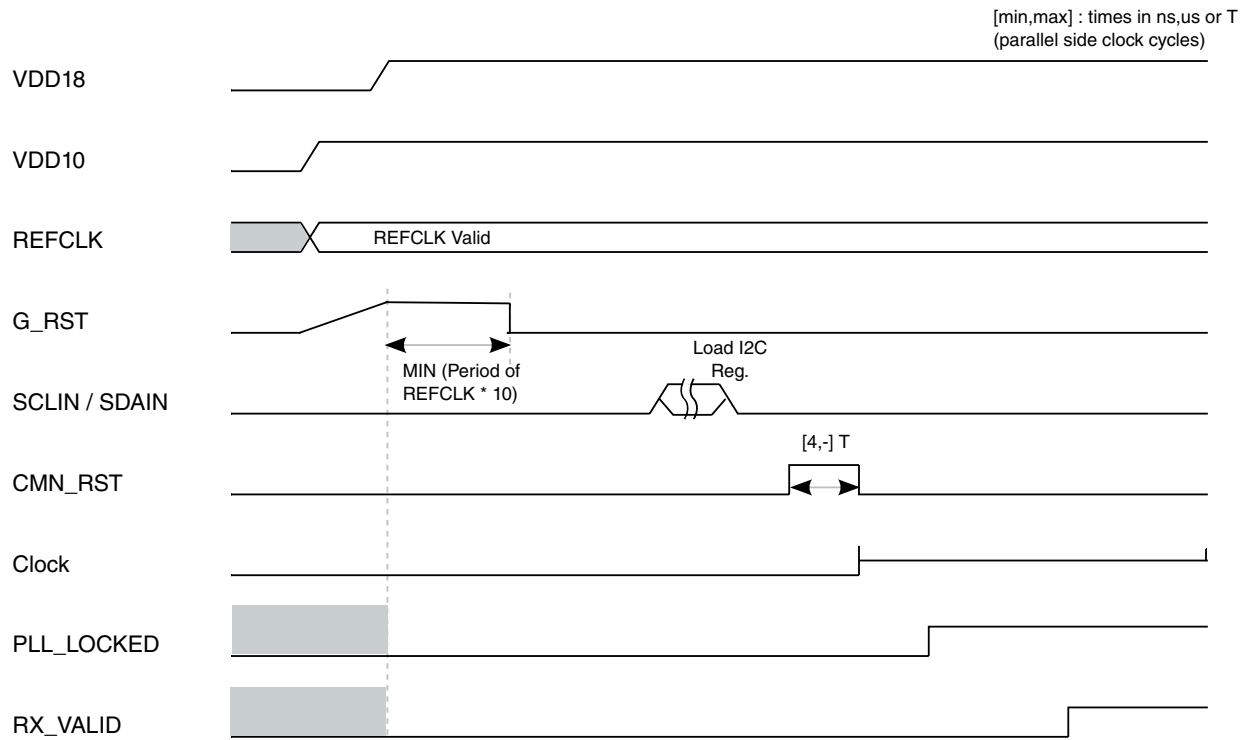

#### 11.3.3.2.4 Driver

Driver amplifies the level of received signal from Serializer to the level that is enough to drive the transmission line. The launch amplitude can be controlled by DRV\_LVL [2:0]. Driver features the pre-emphasis that is effective to reduce ISI jitter caused by the loss of transmission line. The pre-emphasis level can be controlled by EMP\_LVL [3:0].

#### 11.3.3.3 Start-up sequence

To start PCIe PHY operation, RESET (G\_RST) should be invoked at the power up. G\_RST should be pulsed after the power-up following by REFCLK input and setting the asynchronous control inputs. The PHY powerdown and up sequences could be added

after G\_RST sequence for the initialization. The timing restrictions for RESET signal and the typical timing information for the related output signals are shown in the following figure.

Note: All times (widths and delays) are approximate. The order of events is accurate.

**Figure 11-56. Start-up Sequence**

**NOTE**

Before the PHY initialization sequences, all the input signals including REFCLK and power / ground for the PHY should be active and stable. After the PHY initialization sequences (for example, after RX\_VALID = 1), the Link controller initialization including reset could be started (for example, PHY signals to the LINK controller must be neglected before the PHY initialization sequences is fully completed).

**11.3.3.4 Interface power states**

The interface power states are defined as described in the following table. For the power states such as Partial or Slumber, greater power savings can be achieved at a cost of increased exit latency.

**Table 11-56. Interface Power States**

State	Description
PHYRDY (or L0)	The Phy logic and main PLL are both on and active. The interface is synchronized and capable of receiving and sending data.
Partial (or L1)	The Phy logic is powered, but is in a reduced power state. This state allows an additional power savings over normal mode at the cost of additional resume latency.  The exit latency from this state shall be no longer than 10 $\mu$ s (Usually less than 2 $\mu$ s in Samsung PCIe PHY). However, when Automatic Partial to Slumber Transitions are enabled the exit latency from this state shall be no longer than the maximum Slumber exit latency.
Slumber (or L2)	The Phy logic is powered but is in a reduced power state. Power can be aggressively conserved in this mode. Most of the Transmitter and Receiver may be shut off. Main power and clocks are not guaranteed, but REF_CLK is available. The exit latency from this state shall be no longer than 10 ms (Usually less than 500 $\mu$ s in PCIe PHY).

### NOTE

For the PCIe interface, recommended L0s Exit Latency and L1 Exit Latency is less than 64 ns and between 1  $\mu$ s and 2  $\mu$ s respectively. L0s state in the PCIe application is intended as a power savings state between L0 and L1.

#### 11.3.3.5 Multi-channel support

- When the PCIe PHY is implemented to support four channels. Register map demonstrates how this 4-channel PCIe PHY is configured. One CMU block includes the main PLL, bias generator, termination calibration, and the reference clock I/O buffer. 4-channel TRSV block contains the full TX and RX parts including serializer, deserializer, clock and data recovery and high-speed I/Os. This SoC only support one channel phy.
- For the logic sides, interface signal ports are provided for each channel and named with channel number such as "\*\_CH[n]" (For example, \*\_CH0, \*\_CH1, \*\_CH2, and \*\_CH3).
- VDD10 power has to turn on first and then VDD18 power turns on. It is needed to protect damage of thin transistor from unknown situation when 1.8 V power supply only applied to the PHY.
- VDD18 turn on time has to wait at least 0.1  $\mu$ s after VDD10 turns on. But if ramp up time of VDD10 is much slower than 0.1  $\mu$ s, waiting time also has to be increased to meet following figure.

Figure 11-57. Power Up Sequence

### 11.3.4 PCIe PHY Register

The PCIe PHY has programmable test features that are controlled by registers. These internal registers can be accessible through the APB or I2C interface. The PHY comprises CMU part and TRSV part. Only one CMU block exists for the PHY, and one or more TRSV blocks can be implemented according to the system requirements.

This phy only has channel 0 (CH0). Address is word address, SOC Address = Base Address + 4 \* (word address). For each word only byte0 is useful, byte3 ~ 1 are all read zero.

#### 11.3.4.1 PHY Register for CMN Block

The PCIe PHY share a common (CMN) block for the clock and bias generation. The following tables list the capabilities implemented by the PHY design team for internal use.

PCIE\_PHY\_CMN memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page

CMNRST[7:0]	<p>CMN Reset Control</p> <p><b>NOTE:</b> In the PHY, RESET pins for CMN block can be controlled by register for the debug purpose.</p> <p>0xxxxxxx Normal operation (Default)                      10000000 Fine control option for RESET                      ~ Fine control option for RESET                      11111111 Fine control option for RESET</p>

### 11.3.4.2 PHY Register for Transceiver Block

The PCIe PHY has a common (CMN) block and multi-lanes of transceiver (TRSV) can be supported for the application for the high-speed serial data transmission and clock-data recovery. The following descriptions list the capabilities implemented by the PHY design team for internal use. The addresses of register in this chapter are for the transceiver ch0 and addition offset is required for another channel such as ch1 ~ 3.

#### NOTE

- TX and RX parallel data also can have bit and / or byte order change to be flexible with connection errors between the PHY and the LINK controller.
- This BIST mode would be used for ATE test and addition features such as loopback mode can be controlled with the proper register settings. Make sure the powerdown mode control pins are not enabled. (i.e. these powerdown mode pins should be controllable by register in the SoC). These loopback mode are not Compliance mode which is usually implemented in the LINK controller side. When LB\_EN is "high", Loopback mode works. This LB\_EN is used with LB\_MODE[1:0]. If you would like to use TX to RX serial loopback, you should set LB\_EN = "1" and LB\_MODE = "00'.

## 11.4 Universal Serial Bus Controller (USB)

### 11.4.1 Overview

The USB controller block provides high performance USB functionality that conforms to the *Universal Serial Bus Specification*, Rev. 2.0 (Compaq, Hewlett-Packard, Intel, Lucent, Microsoft, NEC, Philips; 2000), and the *On-The-Go and Embedded Host Supplement to the USB Revision 2.0 Specification* (Hewlett-Packard Company, Intel Corporation, LSI Corporation, Microsoft Corporation, Renesas Electronics Corporation, ST-Ericsson; 2012).

The USB controller consists of three independent USB controller cores: two On-The-Go (OTG) controller cores, and one Host-only controller core. Each controller core connects to its dedicated on-chip USB PHY instance using a UTMI interface. See [Features](#) for more details. All three controller cores are single-port cores.

The following figure is a block diagram of USB.

Figure 11-58. USB block diagram

### 11.4.1.1 Features

There are three USB 2.0 controller cores in this chip:

- Controller Core 0 is also named 'OTG1 Core'; its connected port is named 'OTG1 port'.
- Controller Core 1 is also named 'OTG2 Core'; its connected port is named 'OTG2 port'.
- Controller Core 2 is also named 'HSIC'.

The following list provides features of each of the controller cores.

- USB 2.0 Controller Core 0
  - High-Speed/Full-Speed/Low-Speed OTG core
  - HS/FS/LS UTMI compliant interface connected to on-chip UTMI PHY
  - High Speed, Full Speed and Low Speed operation in Host mode (with UTMI transceiver)
  - High Speed, and Full Speed operation in Peripheral mode (with UTMI transceiver)
  - Hardware support for OTG signaling, Session Request Protocol (SRP), Host Negotiation Protocol (HNP), and Attach Detection Protocol (ADP). ADP support includes dedicated timer hardware and register interface.
  - Up to 8 bidirectional endpoints
  - Supports charger detection with USB\_OTG1\_CHD\_B pin and register interface
- USB 2.0 Controller Core 1
  - High-Speed/Full-Speed/Low-Speed OTG core
  - HS/FS/LS UTMI compliant interface connected to on-chip UTMI PHY
  - High Speed, Full Speed and Low Speed operation in Host mode (with UTMI transceiver)
  - High Speed, and Full Speed operation in Peripheral mode (with UTMI transceiver)
  - Hardware support for OTG signaling, Session Request Protocol (SRP), Host Negotiation Protocol (HNP), and Attach Detection Protocol (ADP). ADP support includes basic register interface only.
  - Up to 8 bidirectional endpoints
  - Supports charger detection with register interface only
- USB 2.0 Controller Core 2
  - High-Speed Host-Only core
  - HS UTMI interface connects to on-chip HSIC PHY
- Low-power mode with local and remote wake-up capability
- Embedded DMA controller in each core

### 11.4.1.2 Modes of Operation

The USB has two main modes of operation: normal mode and low power mode.

Each USB OTG controller core can operate in High Speed operation (480 Mbps), Full Speed operation (12 Mbps) and Low Speed operation (1.5 Mbps, Host mode only).

The HSIC controller core supports High Speed operation (other USB speeds are not defined for HSIC).

This chapter explains the operation modes.

#### 11.4.1.2.1 Normal Mode

The OTG controller core can operate in Host mode and Device (Peripheral) mode. The Host-only HSIC controller core can operate in Host mode only.

Each USB controller core has its corresponding port, which can work in one or more interface modes.

#### NOTE

Each controller supports only the interface type listed below. Selecting a different interface type in the PORTSC.PTS field results in unpredictable behavior and may cause the system to hang.

- OTG1 port
  - This port supports on-chip UTMI transceiver only.
- OTG2 port
  - This port supports on-chip UTMI transceiver only.
- Host1 Port
  - This port supports on-chip HSIC transceiver only.

Interface for on-board HSIC compatible USB peripherals.

#### 11.4.1.2.2 Low-Power Mode

Each USB controller core has a low-power mode (Suspend mode) to save power consumption.

As described in the USB 2.0 specification, the device can go into the Suspend state after it sees a constant Idle state on the upstream facing port. The OTG controller core enters Suspend mode after 3 ms of inactivity on the port when it is in Device Operation mode. Host controllers, including the OTG controller in Host mode, do not suspend automatically but can be placed in Suspend mode by software.

Either the local ARM platform or the remote USB Host/Peripheral can initiate a wake-up sequence to resume USB communication. For details about Suspend/Resume, see [USB Power Control](#).

## 11.4.2 External Signals

The table found here describes the external signals of USB.

**Table 11-57. USB External Signals**

Signal	Description	Pad	Mode	Direction
USB_OTG1_ID	OTG1 ID Signal	GPIO1_IO02	ALT7	I
		GPIO1_IO12	ALT7	
		I2C4_SCL	ALT4	
		SD2_WP	ALT4	
USB_OTG1_OC	External Input for VBUS overcurrent detectoin	GPIO1_IO04	ALT1	I
		UART3_RXD	ALT1	
USB_OTG1_PWR	To control PMIC to supply VBUS voltage	GPIO1_IO05	ALT1	O
		UART3_TXD	ALT1

USB_OTG1_DP	OTG1 DP Signal	USB_OTG1_DP	No muxing	IO
USB_OTG1_ID	OTG1 ID Signal	USB_OTG1_ID	No muxing	I
USB_OTG1_REXT	External reference resistor input.	USB_OTG1_REXT	No muxing	IO
USB_OTG2_DN	OTG2 DN Signal	USB_OTG2_DN	No muxing	IO
USB_OTG2_DP	OTG2 DP Signal	USB_OTG2_DP	No muxing	IO
USB_OTG2_ID	OTG2 ID Signal	USB_OTG2_ID	No muxing	I
USB_OTG2_REXT	External reference resistor input.	USB_OTG2_REXT	No muxing	IO

### 11.4.3 Functional Description

These sections describe the functionality of the various building blocks of the USB.

#### 11.4.3.1 USB 2.0 Controller Core 1

The USB 2.0 Controller 1 is an instantiation of an EHCI-compatible core which supports high-, full-, and low-speed operation.

In Host mode, this controller core supports high-, full-, and low-speed operation. In Device mode, it supports high- and full-speed operation.

##### 11.4.3.1.1 Host Mode

The controller supports direct connection of a HS/FS/LS device with on-chip UTMI transceiver.

Although there is no separate Transaction Translator block in the system, the transaction translator function normally associated with a USB 2.0 high speed hub has been implemented within the DMA and protocol engine blocks to support connection to full and low speed devices.

##### 11.4.3.1.2 Peripheral (Device) Mode

- Up to eight bidirectional endpoints
- High/full-speed operation
- Support of HNP, ADP, and SRP
- Remote wake-up capability

#### 11.4.3.2 USB 2.0 Controller Core 1

USB 2.0 Controller Core 1 is an instantiation of EHCI-compatible core which supports High Speed / Full Speed / Low Speed operation.

#### 11.4.3.3 USB Power Control

The USB controller supports suspend and wake-up functionality.

The power control block allows for placing the transceiver in USB low power mode when USB bus is IDLE, and supports local and remote wake-up to bring the transceiver out of USB low power mode when needed. Additionally, the power control block can wake-up the ARM platform from core sleep mode by generating an interrupt.

#### 11.4.3.3.1 Entering Low Power Suspend Mode

In Host operation mode, low power suspend mode is entered as follows:

1. Clear the ASE and PSE bits in USB\_USBCMD, and wait until the AS and PS bits in USB\_USBSTS become "0".
2. Set the "SUSPEND" bit in USB\_PORTSC1.
3. Set the "PHCD" bit in USB\_PORTSC1.

For device operation mode, low power suspend mode is entered as follows:

1. After Host drive is IDLE for 3ms, an SLI interrupt is issued (the "DCSUSPEND" or "SLI" bit in USB\_USBSTS).
2. Set the "PHCD" bit on USB\_PORTSC1

#### 11.4.3.3.2 Wake-Up Events

The power control block monitors the USB bus when the USB core is in the USB suspend state.

Depending on whether the core is on Host or Device mode, a number of wake-up conditions are monitored. Upon detection of a wake-up condition, an interrupt (asynchronous) will be generated to ARM platform if the related wake-up interrupt enable bit is set.

USB wake-up interrupt also re-activates the ARM platform clocks if they were stopped during the suspend.

##### 11.4.3.3.2.1 Host Mode Events

The host controller wakes up on the following events:

- Remote Wake-up Request

A peripheral can request the host to reactivate the bus by driving wake-up signaling on the DM/DP lines. The power control block sends a wake-up request to the USB core when a J-K transition on DM/DP line is detected.

- Wake-Up On Overcurrent

If Wake-Up On Overcurrent is enabled (WKOC bit in the USB core register PORTSC1 is set '1'), the power control block sends a wake-up request to the USB core when an overcurrent event is detected.

- Wake-Up On Disconnect

If Wake-Up On Disconnect is enabled (WKDC bit in the USB core register PORTSC1 is set '1'), the power control block sends a wake-up request to the USB core when a disconnection event is detected (J-SE0/K-SE0 transition on DM/DP line).

- Wake-Up On Connect

If a Wake-Up On Connect is enabled (WKCN bit in the USB core register PORTSC1 is set '1'), the power control sub-block sends a wake-up request to the USB core when the connection event is detected (SE0-J/SE0-K transition on DM/DP line).

For a detailed description of register bits WKOC, WKDC, WKCN, please see [Port Status & Control \(USB\\_PORTSC1\)](#).

## 11.4.3.3.2.2 USB OTG Power Domains

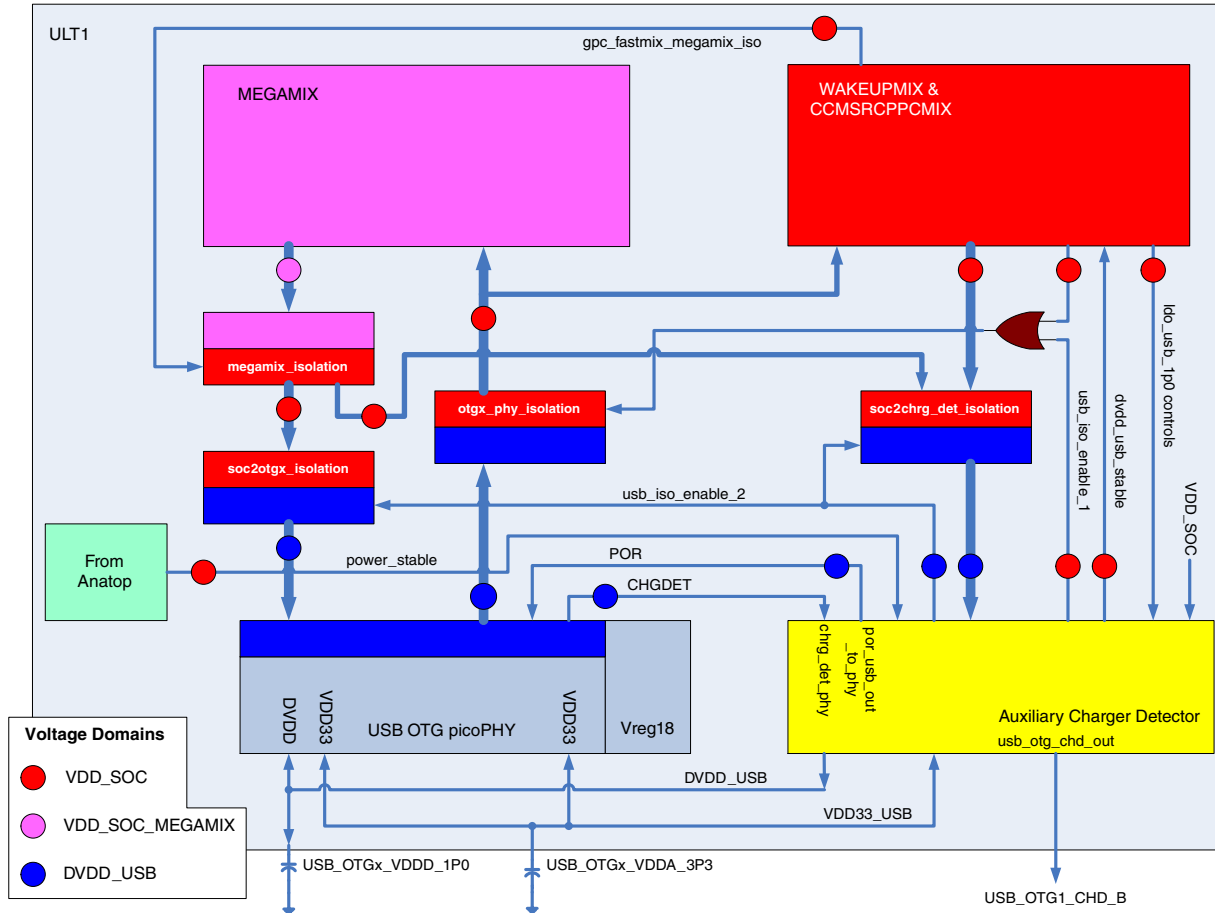

Figure 11-59. USB OTG Power Domains

## 11.4.3.3.2.2.1 Power Overview

USB controller and USB OTG PHY are in different power domains. USB controller locates in megamix power domain. USB OTG PHY has three powers: VDD33, VDD18, and DVDD (1.0 V).

- VDD33 comes from external of the chip, which may be from VBUS or 3.3 V power supply depend on the board design.
- VDD18 is generated by on-chip regulator vreg18 from VDD33.
- DVDD is generated by on-chip regulator inside the Auxiliary Charger Detector from VDD33.

All three OTG PHY power supplies turn on/off at same time.

Auxiliary Charger Detector can detect each power to control related power isolations and generate reset signal for the PHY.

#### 11.4.3.3.2.2.2 Wake-up in Power Down Mode

### NOTE

USB controller or OTG PHY can only power down during USB disconnect mode, power down any part when device/host is connected will cause unknown result.

##### 11.4.3.3.2.2.2.1 Power Down USB Controller

When USB controller is power down, it can be wake-up by changes on PHY port. This is completed by the wake-up logic in the wakeupmix (it is always on power domain).

### NOTE

This wake-up does not generate any interrupts, the wake-up event is only used to power up the system (includes USB controller), software re-initials the USB controller like a system power up event.

The wake-up source in the USB controller power down mode includes following:

- ID
- VBUS/SESS\_VLD
- DP/DM

The related enable signals come from USB\_x\_CTRL1, software set related enable signals before USB controller is power down. The latch based isolation cells keep these enable values.

## 11.4.3.4 Interrupts

### 11.4.3.4.1 USB Core Interrupts

Each USB core uses one dedicated vector in the Interrupt Table. The vector numbers associated with each of the cores can be found in the Interrupt section.

With the exception of the wake-up interrupts, all of the interrupt sources are controlled in the USB Cores. Refer to the [Interrupt Enable Register \(USB\\_USBINTR\)](#) for details.

### 11.4.3.4.2 USB Wake-Up Interrupts

Each USB Core has an associated wake-up interrupt. The wake-up interrupts are generated outside of the USB controller cores, but using the same vector as the corresponding USB controller cores interrupt.

These interrupts are generated by the Power Control blocks which run on the 32 KHz standby clock. The wake-up interrupt is designed to work even when the USB and ARM platform clocks are disabled, such that a wake-up condition on the USB bus can re-activate the ARM platform clocks.

Because the wake-up interrupt is generated and cleared on a 32 KHz clock, this interrupt request responds very slowly to clear actions. For this reason, the software must disable the wake-up interrupt to clear the request flag. Disabling the interrupt masks the request instantaneously as this is clocked by the ARM platform clock. The software should wait for at least three 32 KHz clock cycles before re-enabling this interrupt to allow sufficient time for the request flag to clear. Because this interrupt is only used during low power modes of the USB, it is sufficient to enable the wake-up interrupt just prior to entering the USB suspend mode.

## 11.4.4 USB Operation Model

### 11.4.4.1 Register Interface

Configuration, control and status registers are divided into three categories, identification, capability and operational registers.

#### NOTE

USB controller registers support only DWORD (32-bit) access.

- Identification registers are used to declare the slave interface presence along with the complete set of the hardware configuration parameters.
- Static, read only capability registers define the software limits, restrictions, and capabilities of the host/device controller.
- Operational registers are dynamic control or status registers that may be read only, read/write, or read/write-to-clear. The following sections define the use of these registers.

EHCI registers are listed alongside device registers to show the complementary nature of host and device control.

The following table describes the Interface register sets.

**Table 11-58. Interface Register Sets**

Offset	Register Set	Explanation
000h-07Ch	Identification Registers	Identification registers are used to declare the slave interface presence and include a table of the hardware configuration parameters.

*Table continues on the next page...*

**Table 11-58. Interface Register Sets (continued)**

100h-124h	Capability Registers	Capability registers specify the limits, restrictions, and capabilities of a host/device controller implementation.  These values are used as parameters to the host/device controller driver.
080h-0FCh 140h-1FCh	Operational Registers	Operational registers are used by the system software to control and monitor the operational state of the host/device controller.

### 11.4.4.1.1 Configuration, Control and Status Register Set

The following table describes the Device/Host capability registers.

**Table 11-59. Device/Host Capability Registers**

Offset	Size (Bytes)	Mnemonic	Register Name	Device Mode	Host Mode
000h	4	USB_x_ID	Identification Register	O	O
004h	4	USB_x_HWGENERAL	General Hardware Parameters	O	O

1C4		USB_x_ENDPTCTRL1			
...		....			
1DCh		USB_x_ENDPTCTRL7			

**NOTE**

"O" means the register is available in host/device operation mode;

"X" means the register is reserved in host/device operation mode

### 11.4.4.1.2 Identification Registers

Identification registers are used to declare the slave interface presence and include a table of the hardware configuration parameters.

### 11.4.4.1.3 OTG Operations

#### 11.4.4.1.3.1 Register Bits

In the previous section, the Register interface has behaviors described for device mode and behaviors described for host mode. However, for OTG operations it is necessary to perform tasks independent of the controller mode.

The following figure shows the controller mode.

**Figure 11-60. Controller Mode**

To this end, listed below are the register bits that are used for OTG operations, which are independent of the controller mode and are also not affected by a write to the reset bit in the USBCMD register:

All Identification Registers

All Device/Host Capability Registers

OTGSC: All bits

PORTSC1:

Physical Interface Select

Physical Interface Serial Select

Physical Interface Data Width

Physical Interface Low Power

Physical Interface Wake Signals

Port Indicators

Port Power

### 11.4.4.2 Host Data Structures

This section defines the interface data structures used to communicate control, status, and data between HCD (software) and the Enhanced Host Controller (hardware).

The data structure definitions in this chapter support a 32-bit memory buffer address space. The interface consists of a Periodic Schedule, Periodic Frame List, Asynchronous Schedule, Isochronous Transaction Descriptors, Split-transaction Isochronous Transfer Descriptors, Queue Heads, and Queue Element Transfer Descriptors.

The periodic frame list is the root of all periodic (isochronous and interrupt transfer type) transfers for the host controller. The asynchronous list is the root for all the bulk and control transfers. Isochronous data streams are managed using Isochronous Transaction Descriptors. Isochronous split-transaction data streams are managed with Split-transaction Isochronous Transfer Descriptors. All Interrupt, Control, and Bulk data streams are managed via queue heads and Queue Element Transfer Descriptors. These data structures are optimized to reduce the total memory footprint of the schedule and to reduce (on average) the number of memory accesses needed to execute a USB transaction.

Note that software must ensure that no interface data structure reachable by the EHCI host controller spans a 4 K-page boundary.

The data structures defined in this section are (from the host controller's perspective) a mix of read-only and read/writeable fields. The host controller must preserve the read-only fields on all data structure writes.

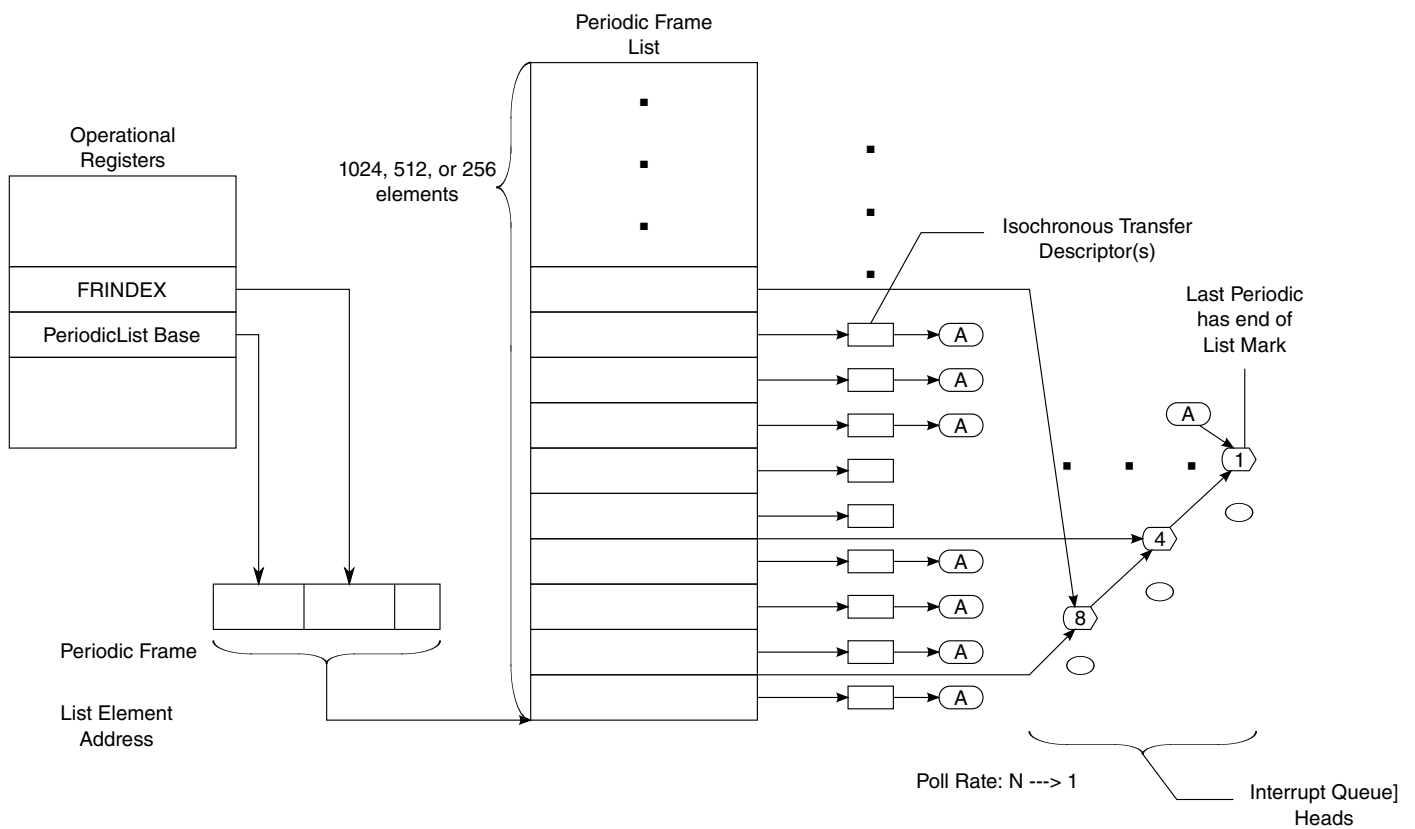

### 11.4.4.2.1 Periodic Frame List

This schedule is for all periodic transfers (isochronous and interrupt). The periodic schedule is referenced from the operational registers space using the USB\_PERIODICLISTBASE address register and the USB\_FRINDEX register.

The periodic schedule is based on an array of pointers called the Periodic Frame List.

The USB\_PERIODICLISTBASE address register is combined with the USB\_FRINDEX register to produce a memory pointer into the frame list. The Periodic Frame List implements a sliding window of work over time.

The following figure shows the organization of periodic schedule.

**Figure 11-61. Periodic Schedule Organization**

Split transaction Interrupt, Bulk and Control are also managed using queue heads and queue element transfer descriptors.

The periodic frame list is a 4 K-page aligned array of Frame List Link pointers. The length of the frame list may be programmable. The programmability of the periodic frame list is exported to system software via the USB\_HCCPARAMS register. If non-programmable, the length is 1024 elements. If programmable, the length can be selected by system software as one of 256, 512, or 1024 elements. An implementation must

support all three sizes. Programming the size (that is, the number of elements) is accomplished by system software writing the appropriate value into Frame List Size field in the USB\_USBCMD register.

Frame List Link pointers direct the host controller to the first work item in the frame's periodic schedule for the current micro-frame. The link pointers are aligned on DWord boundaries within the Frame List.

The table below illustrates the format of the Frame list element pointer.

**Table 11-60. Format of Frame List Element Pointer**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Frame List Link Pointer																											0	Typ	03-00H			

Frame List Link pointers always reference memory objects that are 32-byte aligned. The referenced object may be an isochronous transfer descriptor for high-speed devices, a split-transaction isochronous transfer descriptor (for full-speed isochronous endpoints), or a queue head (used to support high-, full- and low-speed interrupt). System software should not place non-periodic schedule items into the periodic schedule. The least significant bits in a frame list pointer are used to key the host controller as to the type of object the pointer is referencing.

The least significant bit is the T-Bit (bit 0). When this bit is set to a one, the host controller never uses the value of the frame list pointer as a physical memory pointer. The Typ field is used to indicate the exact type of data structure being referenced by this pointer. The value encodings are.

**Table 11-61. Typ Field Value Definitions**

Value	Meaning
00b	Isochronous Transfer Descriptor
01b	Queue Head
10b	Split Transaction Isochronous Transfer Descriptor.
11b	Frame Span Traversal Node.

#### 11.4.4.2 Asynchronous List Queue Head Pointer

The Asynchronous Transfer List (based at the USB\_ASYNC\_LIST\_ADDR register) is where all of the control and bulk transfers are managed.

Host controllers use this list only when it reaches the end of the periodic list, the periodic list is disabled, or the periodic list is empty.

**Figure 11-62. Asynchronous Schedule Organization**

The Asynchronous list is a simple circular list of queue heads. The USB\_ASYNC\_LIST\_ADDR register is simply a pointer to the next queue head. This implements a pure round-robin service for all queue heads linked into the asynchronous list.

### 11.4.4.2.3 Isochronous (High-Speed) Transfer Descriptor (iTID)

The format of an isochronous transfer descriptor is shown in the table below.

This structure is used only for high-speed isochronous endpoints. All other transfer types should use queue structures. Isochronous TDs must be aligned on a 32-byte boundary.

**Table 11-62. Isochronous Transaction Descriptor (iTID)**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Host Controller Read/Write

Host Controller Read Only

These fields may be modified by the host controller if the I/O field indicates an OUT.

#### 11.4.4.2.3.1 Next Link Pointer

The first DWord of an iTD is a pointer to the next schedule data structure.

The following table describes the Next Schedule Element pointer field.

**Table 11-63. Next Schedule Element Pointer**

Bit	Description
31-5 Link Pointer (LP)	These bits correspond to memory address signals [31:5], respectively. This field points to another Isochronous Transaction Descriptor (iT D/siT D) or Queue Head (QH).

*Table continues on the next page...*

**Table 11-63. Next Schedule Element Pointer (continued)**

4-3 Reserved	These bits are reserved and their value has no effect on operation. Software should initialize this field to zero.
2-1 QH/(s)iTD Select (Typ)	This field indicates to the Host Controller whether the item referenced is an iTD, siTD or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are:  Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor) 11b FSTN (frame span traversal node)
0 Terminate (T)	1= Link Pointer field is not valid. 0= Link Pointer field is valid.

**11.4.4.2.3.2 iTD Transaction Status and Control List**

DWords 1 through 8 are eight slots of transaction control and status.

Each transaction description includes:

- Status results field
- Transaction length (bytes to send for OUT transactions and bytes received for IN transactions).
- Buffer offset. The PG and Transaction X Offset fields are used with the buffer pointer list to construct the starting buffer address for the transaction.

The host controller uses the information in each transaction description plus the endpoint information contained in the first three DWords of the Buffer Page Pointer list, to execute a transaction on the USB.

The following table describes iTD Transaction Status and Control fields.

**Table 11-64. iTD Transaction Status and Control**

Bit	Description								
31-28 Status	This field records the status of the transaction executed by the host controller for this slot. This field is a bit vector with the following encoding:								
	<table border="1"> <thead> <tr> <th>Bit</th> <th>Definition</th> </tr> </thead> <tbody> <tr> <td>31</td> <td>Active. Set to one by software to enable the execution of an isochronous transaction by the Host Controller. When the transaction associated with this descriptor is completed, the Host Controller sets this bit to zero indicating that a transaction for this element should not be executed when it is next encountered in the schedule.</td> </tr> <tr> <td>30</td> <td>Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). If an overrun condition occurs, no action is necessary.</td> </tr> <tr> <td>29</td> <td>Babble Detected. Set to one by the Host Controller during status update when "babble" is detected during the transaction generated by this descriptor.</td> </tr> </tbody> </table>	Bit	Definition	31	Active. Set to one by software to enable the execution of an isochronous transaction by the Host Controller. When the transaction associated with this descriptor is completed, the Host Controller sets this bit to zero indicating that a transaction for this element should not be executed when it is next encountered in the schedule.	30	Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). If an overrun condition occurs, no action is necessary.	29	Babble Detected. Set to one by the Host Controller during status update when "babble" is detected during the transaction generated by this descriptor.
Bit	Definition								
31	Active. Set to one by software to enable the execution of an isochronous transaction by the Host Controller. When the transaction associated with this descriptor is completed, the Host Controller sets this bit to zero indicating that a transaction for this element should not be executed when it is next encountered in the schedule.								
30	Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). If an overrun condition occurs, no action is necessary.								
29	Babble Detected. Set to one by the Host Controller during status update when "babble" is detected during the transaction generated by this descriptor.								

*Table continues on the next page...*

**Table 11-64. iTD Transaction Status and Control (continued)**

Bit	Description
28	Transaction Error (XactErr). Set to one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). This bit may only be set for isochronous IN transactions.
27-16 Transaction X Length	For an OUT, this field is the number of data bytes the host controller sends during the transaction. The host controller is not required to update this field to reflect the actual number of bytes transferred during the transfer. For an IN, the initial value of the endpoint to deliver. During the status update, the host controller writes back the field is the number of bytes the host expects the number of bytes successfully received. The value in this register is the actual byte count (0±zero length data, 1±one byte, 2±two bytes, etc.). The maximum value this field may contain is 0xC00 (3072).
15 Interrupt On Complete (IOC)	If this bit is set to one, it specifies that when this transaction completes, the Host Controller should issue an interrupt at the next interrupt threshold.
14-12 Page Select (PG)	These bits are set by software to indicate which of the buffer page pointers the offset field in this slot should be concatenated to produce the starting memory address for this transaction. The valid range of values for this field is 0 to 6.
11-0 Transaction X Offset	This field is a value that is an offset, expressed in bytes, from the beginning of a buffer. This field is concatenated onto the buffer page pointer indicated in the adjacent PG field to produce the starting buffer address for this transaction.

#### 11.4.4.2.3.3 iTD Buffer Page Pointer List (Plus)

DWords 9-15 of an isochronous transaction descriptor are nominally page pointers (4 K aligned) to the data buffer for this transfer descriptor. This data structure requires the associated data buffer to be contiguous (relative to virtual memory), but allows the physical memory pages to be non-contiguous.

Seven page pointers are provided to support the expression of eight isochronous transfers. The seven pointers allow for 3 (transactions) \* 1024 (maximum packet size) \* 8 (transaction records) (24576 bytes) to be moved with this data structure, regardless of the alignment offset of the first page.

Because each pointer is a 4 K aligned page pointer, the least significant 12 bits in several of the page pointers are used for other purposes.

The tables below illustrate the field descriptions.

**Table 11-65. iTD Buffer Pointer Page 0 (Plus)**

Bit	Description
31-12 Buffer Pointer (Page 0)	This is a 4 K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11-8	This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.

*Table continues on the next page...*

**Table 11-65. iTD Buffer Pointer Page 0 (Plus) (continued)**

Bit	Description
Endpoint Number (Endpt)	
7 Reserved	Bit reserved for future use and should be initialized by software to zero.
6-0 Device Address	This field selects the specific device serving as the data source or sink.

**Table 11-66. iTD Buffer Pointer Page 1 (Plus)**

Bit	Description
31-12 Buffer Pointer (Page 1)	This is a 4K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11 Direction (I/O)	0 = OUT; 1 = IN. This field encodes whether the high-speed transaction should use an IN or OUT PID.
10-0 Maximum Packet Size	This directly corresponds to the maximum packet size of the associated endpoint ( <i>wMaxPacketSize</i> ). This field is used for high-bandwidth endpoints where more than one transaction is issued per transaction description (per micro-frame). This field is used with the <i>Multi</i> field to support high-bandwidth pipes. This field is also used for all IN transfers to detect packet babble. Software should not set a value larger than 1024 (400h). Any value larger yields undefined results.

**Table 11-67. iTD Buffer Pointer Page 2 (Plus)**

Bit	Description
31-12 Buffer Pointer	This is a 4K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11-2 Reserved	This bit reserved for future use and should be set to zero.
1-0 Multi	This field is used to indicate to the host controller the number of transactions that should be executed per transaction description (per micro-frame). The valid values are:  Value Meaning 00b Reserved. A zero in this field yields undefined results. 01b One transaction to be issued for this endpoint per micro- frame. 10b Two transactions to be issued for this endpoint per micro- frame. 11b Three transactions to be issued for this endpoint per micro- frame.

**Table 11-68. iTD Buffer Pointer Page 3-6**

Bit	Description
31-12 Buffer Pointer	This is a 4 K aligned pointer to physical memory. Corresponds to memory address bits [31:12].

*Table continues on the next page...*

**Table 11-68. iTD Buffer Pointer Page 3-6 (continued)**

Bit	Description
11-0 Reserved	These bits reserved for future use and should be set to zero.

#### 11.4.4.2.4 Split Transaction Isochronous Transfer Descriptor (siTD)

All Full-speed isochronous transfers through the internal transaction translator are managed using the siTD data structure. This data structure satisfies the operational requirements for managing the split transaction protocol.

The following table shows the Split Transaction Isochronous Transfer Descriptor (siTD).

**Table 11-69. Split Transaction Isochronous Transfer Descriptor**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Addr

Host Controller Read/Write

Host Controller Read Only

##### 11.4.4.2.4.1 Next Link Pointer

DWord0 of a siTD is a pointer to the next schedule data structure.

The following table describes the Next Link Pointer fields.

**Table 11-70. Next Link Pointer**

Bit	Description
31-5	Next Link Pointer (LP). This field contains the address of the next data object to be processed in the periodic list and corresponds to memory address signals [31:5], respectively.
4-3	Reserved. These bits must be written as zeros.
2-1	QH/(s)iTD Select (Typ). This field indicates to the Host Controller whether the item referenced is an iTD/siTD or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are:  Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor) 11b FSTN (frame span traversal node)
0	Terminate (T).  1 = Link Pointer field is not valid. 0 = Link Pointer is valid.

**11.4.4.2.4.2 siTD Endpoint Capabilities/Characteristics**

DWords 1 and 2 specify static information about the full-speed endpoint, the addressing of the parent Companion Controller, and micro-frame scheduling control.

The tables below describe the Endpoint and transaction translator characteristics and micro-frame schedule control fields.

**Table 11-71. Endpoint and Transaction Translator Characteristics**

Bit	Description
31	Direction (I/O). 0 = OUT; 1 = IN. This field encodes whether the full-speed transaction should be an IN or OUT.
30-24	Port Number. This field is the port number of the recipient Transaction Translator.
23	Reserved. Bit reserved and should be set to zero.
22-16	Hub Address. This field holds the device address of the Companion Controllers' hub.
15-12	Reserved. Field reserved and should be set to zero.
11-8	Endpoint Number (Endpt). This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.
7	Reserved. Bit is reserved for future use. It should be set to zero.
6-0	Device Address. This field selects the specific device serving as the data source or sink.

**Table 11-72. Micro-frame Schedule Control**

Bit	Description
31-16	Reserved. This field reserved for future use. It should be set to zero.

*Table continues on the next page...*

**Table 11-72. Micro-frame Schedule Control (continued)**

Bit	Description
15-8	Split Completion Mask (mFrame C-Mask). This field (along with the <i>Active</i> and <i>SplitX-state</i> fields in the <i>Status</i> byte) is used to determine during which micro-frames the host controller should execute complete-split transactions. When the criteria for using this field is met, an all zeros value has undefined behavior. The host controller uses the value of the three low-order bits of the FRINDEX register to index into this bit field. If the FRINDEX register value indexes to a position where the <i>mFrame C-Mask</i> field is a one, then this siTD is a candidate for transaction execution. There may be more than one bit in this mask set.
7-0	Split Start Mask (mFrame S-mask). This field (along with the <i>Active</i> and <i>SplitX-state</i> fields in the <i>Status</i> byte) is used to determine during which micro-frames the host controller should execute start-split transactions. The host controller uses the value of the three low-order bits of the FRINDEX register to index into this bit field. If the FRINDEX register value indexes to a position where the <i>mFrame S-mask</i> field is a one, then this siTD is a candidate for transaction execution. An all zeros value in this field, in combination with existing periodic frame list has undefined results.

#### 11.4.4.2.4.3 siTD Transfer State

DWords 3-6 are used to manage the state of the transfer.

The following table describes siTD transfer state fields.

**Table 11-73. siTD Transfer Status and Control**

Bit	Description
31	Interrupt On Complete (ioc). 0 = Do not interrupt when transaction is complete. 1 = Do interrupt when transaction is complete. When the host controller determines that the split transaction has completed it asserts a hardware interrupt at the next interrupt threshold.
30	Page Select (P). Used to indicate which data page pointer should be concatenated with the <i>CurrentOffset</i> field to construct a data buffer pointer (0 selects <i>Page 0</i> pointer and 1 selects <i>Page 1</i> ). The host controller is not required to write this field back when the siTD is retired ( <i>Active</i> bit transitioned from a one to a zero).
29-26	Reserved. This field reserved for future use and should be set to zero.
25-16	Total Bytes To Transfer. This field is initialized by software to the total number of bytes expected in this transfer. Maximum value is 1023 (3FFh)
15-8	$\mu$ Frame Complete-split Progress Mask (C-prog-Mask). This field is used by the host controller to record which split-completes has been executed.
<b>7-0: Status—This field records the status of the transaction executed by the host controller for this slot. It is a bit vector with the encoding shown in the following rows.</b>	
7	Active. Set to one by software to enable the execution of an isochronous split transaction by the Host Controller.
6	ERR. Set to a one by the Host Controller when an ERR response is received from the Companion Controller.
5	Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). In the case of an under run, the Host Controller transmits an incorrect CRC (thus invalidating the data at the endpoint). If an overrun condition occurs, no action is necessary.
4	Babble Detected. Set to a one by the Host Controller during status update when "babble" is detected during the transaction generated by this descriptor.

*Table continues on the next page...*

**Table 11-73. siTD Transfer Status and Control (continued)**

Bit	Description
3	Transaction Error (XactErr). Set to a one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). This bit is set only for IN transactions.
2	Missed Micro-Frame. The host controller detected that a host-induced hold-off caused the host controller to miss a required complete-split transaction.
1	Split Transaction State (SplitXstate). The bit encodings are:  Value Meaning  00b Do Start Split.  This value directs the host controller to issue a Start split transaction to the endpoint when a match is encountered in the S-mask.  01b Do Complete Split.  This value directs the host controller to issue a Complete split transaction to the endpoint when a match is encountered in the C-mask.
0	Reserved. Bit reserved for future use and should be set to zero.

**11.4.4.2.4.4 siTD Buffer Pointer List (plus)**

DWords 4 and 5 are the data buffer page pointers for the transfer. This structure supports one physical page cross. The most significant 20 bits of each DWord in this section are the 4 K (page) aligned buffer pointers.

The least significant 12 bits of each DWord are used as additional transfer state. The following table describes the siTD buffer pointer fields.

**Table 11-74. Buffer Page Pointer List (plus)**

Bit	Description
31-12	Buffer Pointer List. Bits [31:12] of DWords 4 and 5 are 4 K page aligned physical memory addresses. These bits correspond to physical address bits [31:12] respectively. The lower 12 bits in each pointer are defined and used as specified below. The field <i>P</i> (see <a href="#">siTD Transfer State</a> ) specifies the <i>current</i> active pointer.
Bits 11-0 (Page 0)	Current Offset—The 12 least significant bits of the Page 0 pointer are the current byte offset for the current page pointer (as selected with the page indicator bit ( <i>P</i> field)). The host controller is not required to write this field back when the siTD is retired ( <i>Active</i> bit transitioned from a one to a zero).
<b>Bits 11-0 (Page 1)—The least significant bits of the Page 1 pointer are split into three subfields as shown in the following rows.</b>	
11-5 (Page 1)	Reserved
4-3 (Page 1)	Transaction position (TP). This field is used with T-count to determine whether to send <i>all</i> , <i>first</i> , <i>middle</i> , or <i>last</i> with each outbound transaction payload. System software must initialize this field with the appropriate starting value. The host controller must correctly manage this state during the lifetime of the transfer. The bit encodings are:  Value Meaning

*Table continues on the next page...*

**Table 11-74. Buffer Page Pointer List (plus) (continued)**

Bit	Description
	00b All. The entire full-speed transaction data payload is in this transaction (that is, less than or equal to 188 bytes). 01b Begin. This is the first data payload for a full-speed that is greater than 188 bytes. 10b Mid. This is the <i>middle</i> payload for a full-speed OUT transaction that is larger than 188 bytes. 11b End. This is the <i>last</i> payload for a full-speed OUT transaction that was larger than 188 bytes.
2-0 (Page 1)	Transaction count (T-Count). Software initializes this field with the number of OUT start-splits this transfer requires. Any value larger than 6 is undefined.

#### 11.4.4.2.4.5 siTD Back Link Pointer

DWord 6 of a siTD is simply another schedule link pointer. This pointer is always zero, or references a siTD, and it cannot reference any other schedule data structure.

The following table describes the siTD back link pointer fields.

**Table 11-75. siTD Back Link Pointer**

Bit	Description
31-5	siTD Back Pointer. This field is a physical memory pointer to a siTD.
4-1	Reserved. This field is reserved for future use. It should be set to zero.
0	Terminate (T). 1 = siTD Back Pointer field is not valid. 0 = siTD Back Pointer field is valid.

#### 11.4.4.2.5 Queue element transfer descriptor (qTD)

This data structure is only used with a queue head. It describes one or more USB transactions to transfer up to 20480 (5\*4096) bytes.

The structure contains two structure pointers used for queue advancement, a DWord of transfer state, and a five-element array of data buffer pointers.

It is 32 bytes and must be physically contiguous.

The buffer associated with this transfer must be virtually contiguous. The buffer may start on any byte boundary; however, for optimal utilization of on-chip busses it is recommended to align the buffers on a 32-byte boundary. A separate buffer pointer list element must be used for each physical page in the buffer, regardless of whether the buffer is physically contiguous.

Host controller updates (host controller writes) to stand-alone qTDs only occur during transfer retirement. References in the following bit field definitions of updates to the qTD are to the qTD portion of a queue head.

The following table shows the queue element transfer descriptor data structure.

**Table 11-76. Queue element transfer descriptor data structure**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Addr

Buffer Pointer (page 4)																	Reserved										1F-1C					

1. 08-0F: Transfer Results

Host Controller Read/Write

Host Controller Read Only

Queue Element Transfer Descriptors must be aligned on 32-byte boundaries.

### 11.4.4.2.5.1 Next qTD Pointer

The first DWord of an element transfer descriptor is a pointer to another transfer element descriptor.

The following table describes Next qTD pointer fields.

**Table 11-77. qTD Next Element Transfer Pointer (DWord 0)**

Bit	Description
31-5	Next Transfer Element Pointer. This field contains the physical memory address of the next qTD to be processed. The field corresponds to memory address signals[31:5], respectively.
4-1	Reserved
0	Terminate (T). 1= pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Host Controller that there are no more valid entries in the queue.

#### 11.4.4.2.5.2 Alternate Next qTD Pointer

The second DWord of a queue element transfer descriptor is used to support hardware-only advance of the data stream to the next transfer descriptor on short packet. To be more explicit the host controller always uses this pointer when the current qTD is retired due to short packet.

The following table describes the TD Alternate Next Element Transfer Pointer field descriptions.

**Table 11-78. TD Alternate Next Element Transfer Pointer (DWord 1)**

Bit	Description
31-5	Alternate Next Transfer Element Pointer. This field contains the physical memory address of the next qTD to be processed in the event that the current qTD execution encounters a short packet (for an IN transaction). The field corresponds to memory address signals [31:5], respectively.
4-1	Reserved
0	Terminate (T). 1= pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Host Controller that there are no more valid entries in the queue.

#### 11.4.4.2.5.3 qTD Token

The third DWord of a queue element transfer descriptor contains most of the information the host controller requires to execute a USB transaction (the remaining endpoint-addressing information is specified in the queue head).

#### NOTE

The field descriptions forward reference fields defined in the queue head. Where necessary, these forward references are preceded with a QH notation.

The following table describes the TD Token fields.

**Table 11-79. TD Token (DWord 2)**

Bit	Description						
31 Data Toggle	This is the data toggle sequence bit. The use of this bit depends on the setting of the <i>Data Toggle Control</i> bit in the queue head.						
30-16 Total Bytes to Transfer	This field specifies the total number of bytes to be moved with this transfer descriptor. This field is decremented by the number of bytes actually moved during the transaction, only on the successful completion of the transaction. The maximum value software may store in this field is 5 * 4K (5000H). This is the maximum number of bytes 5 page pointers can access. If the value of this field is zero when the host controller fetches this transfer descriptor (and the active bit is set), the host controller executes a zero-length transaction and retires the transfer descriptor. It is not a requirement for OUT transfers that <i>Total Bytes To Transfer</i> be an even multiple of QHD.Maximum Packet Length. If software builds such a transfer descriptor for an OUT transfer, the last transaction is always less than QHD.Maximum Packet Length.  Although it is possible to create a transfer up to 20K this assumes the 1 <sup>st</sup> offset into the first page is 0. When the offset cannot be predetermined, crossing past the 5th page can be guaranteed by limiting the total bytes to 16K**. Therefore, the maximum recommended transfer is 16 K(4000H).						
15 Interrupt On Complete (IOC)	If this bit is set to a one, it specifies that when this qTD is completed, the Host Controller should issue an interrupt at the next interrupt threshold.						
14-12 Current Page (C_Page)	This field is used as an index into the qTD buffer pointer list. Valid values are in the range 0H to 4H. The host controller is not required to write this field back when the qTD is retired.						
11-10 Error Counter (CERR)	This field is a 2-bit down counter that keeps track of the number of consecutive Errors detected while executing this qTD. If this field is programmed with a non-zero value during set-up, the Host Controller decrements the count and writes it back to the qTD if the transaction fails. If the counter counts from one to zero, the Host Controller marks the qTD inactive, sets the <i>Halted</i> bit to a one, and error status bit for the error that caused <i>CERR</i> to decrement to zero. An interrupt is generated if the <i>USB Error Interrupt Enable</i> bit in the <i>USBINTR</i> register is set to a one. If HCD programs this field to zero during set-up, the Host Controller does not count errors for this qTD and there is no limit on the retries of this qTD. Note that write-backs of intermediate execution state are to the queue head overlay area, not the qTD.  Transaction Error - Decrement Data Buffer Error - No Decrement <sup>3</sup> Stalled - No Decrement <sup>1</sup> Babble Detected - No Decrement <sup>1</sup> No Error - No Decrement <sup>2</sup>						
	<table border="1"> <thead> <tr> <th>Error</th> <th>Decrement Counter</th> </tr> </thead> <tbody> <tr> <td>1</td> <td>Detection of Babble or Stall automatically halts the queue head. Thus, count is not decremented</td> </tr> <tr> <td>2</td> <td>If the <i>EPS</i> field indicates a HS device or the queue head is in the Asynchronous Schedule (and <i>PIDCode</i> indicates an IN or OUT) and a bus transaction completes and the host controller does not detect a transaction error, then the host controller should reset <i>CERR</i> to extend the total number of errors for this transaction. For example, <i>CERR</i> should be reset with maximum value (3) on each successful completion of a transaction. The host controller must never reset this field if the value at the start of the transaction is 00b.</td> </tr> </tbody> </table>	Error	Decrement Counter	1	Detection of Babble or Stall automatically halts the queue head. Thus, count is not decremented	2	If the <i>EPS</i> field indicates a HS device or the queue head is in the Asynchronous Schedule (and <i>PIDCode</i> indicates an IN or OUT) and a bus transaction completes and the host controller does not detect a transaction error, then the host controller should reset <i>CERR</i> to extend the total number of errors for this transaction. For example, <i>CERR</i> should be reset with maximum value (3) on each successful completion of a transaction. The host controller must never reset this field if the value at the start of the transaction is 00b.
Error	Decrement Counter						
1	Detection of Babble or Stall automatically halts the queue head. Thus, count is not decremented						
2	If the <i>EPS</i> field indicates a HS device or the queue head is in the Asynchronous Schedule (and <i>PIDCode</i> indicates an IN or OUT) and a bus transaction completes and the host controller does not detect a transaction error, then the host controller should reset <i>CERR</i> to extend the total number of errors for this transaction. For example, <i>CERR</i> should be reset with maximum value (3) on each successful completion of a transaction. The host controller must never reset this field if the value at the start of the transaction is 00b.						

Table continues on the next page...

Table 11-79. TD Token (DWord 2) (continued)

Bit	Description
	See <a href="#">Split Transaction Interrupt</a> for CERR adjustment rules when the EPS field indicates a FS or LS device and the queue head is in the Periodic Schedule. See <a href="#">Asynchronous - Do Complete Split</a> for CERR adjustment rules when the EPS field indicates a FS or LS device, the queue head is in the Asynchronous schedule and the <i>PIDCode</i> indicates a SETUP.
3	Data buffer errors are host problems. They don't count against the device's retries.
	<b>NOTE:</b> Software must not program CERR to a value of zero when the EPS field is programmed with a value indicating a Full- or Low-speed device. This combination could result in undefined behavior.
9-8 PID Code	This field is an encoding of the token, which should be used for transactions associated with this transfer descriptor. Encodings are:
00b	OUT Token generates token (E1H)
01b	IN Token generates token (69H)
10b	SETUP Token generates token (2DH) (undefined if endpoint is an interrupt, the queue head is non-zero) transfer type, for example, <i>μFrame S-mask</i> field in.
11b	Reserved
7-0 Status	This field is used by the Host Controller to communicate individual command execution states back to HCD. This field contains the status of the last transaction performed on this qTD. The bit encodings are:
Bit	Status Field Description
7	Active. Set to one by software to enable the execution of transactions by the Host Controller.
6	Halted. Set to one by the Host Controller during status updates to indicate that a serious error has occurred at the device/endpoint addressed by this qTD. This can be caused by babble, the error counter counting down to zero, or reception of the STALL handshake from the device during a transaction. Any time that a transaction results in the Halted bit being set to a one, the Active bit is also set to zero.
5	Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overflow) or is unable to supply data fast enough during transmission (under run). If an overflow condition occurs, the Host Controller forces a timeout condition on the USB, invalidating the transaction at the source. If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.
4	Babble Detected. Set to a one by the Host Controller during status update when "babble" is detected during the transaction. In addition to setting this bit, the Host Controller also sets the <i>Halted</i> bit to a one. Because "babble" is considered a fatal error for the transfer, setting the Halted bit to a one insures that no more transactions occur because of this descriptor.
3	Transaction Error (XactErr). Set to a one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.

Table continues on the next page...

**Table 11-79. TD Token (DWord 2) (continued)**

Bit	Description	
	2	Missed Micro-Frame. This bit is ignored unless the <i>QH.EPS</i> field indicates a full- or low-speed endpoint and the queue head is in the periodic list. This bit is set when the host controller detected that a host-induced hold-off caused the host controller to miss a required complete-split transaction. If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.
	1	<p>Split Transaction State (SplitXstate). This bit is ignored by the host controller unless the <i>QH.EPS</i> field indicates a full- or low-speed endpoint. When a Full- or Low-speed device, the host controller uses this bit to track the state of the split-transaction. The functional requirements of the host controller for managing this state bit and the split transaction protocol depends on whether the endpoint is in the periodic or asynchronous schedule. The bit encodings are:</p> <p>Value Meaning</p> <p>0b Do Start Split. This value directs the host controller to issue a Start split transaction to the endpoint.</p> <p>1b Do Complete Split. This value directs the host controller to issue a Complete split transaction to the endpoint.</p>
	0	<p>Ping State (P)/ERR. If the <i>QH.EPS</i> field indicates a High-speed device and the <i>PID_Code</i> indicates an OUT endpoint, then this is the state bit for the Ping protocol. The bit encodings are:</p> <p>Value Meaning</p> <p>0b Do OUT. This value directs the host controller to issue an OUT PID to the endpoint.</p> <p>1b Do Ping. This value directs the host controller to issue a PING PID to the endpoint.</p> <p>If the <i>QH.EPS</i> field does not indicate a High-speed device, then this field is used as an error indicator bit. It is set to a one by the host controller whenever a periodic split-transaction receives an ERR handshake.</p>

**11.4.4.2.5.4 qTD Buffer Page Pointer List**

The last five DWords of a queue element transfer descriptor is an array of physical memory address pointers. These pointers reference the individual pages of a data buffer.

System software initializes Current Offset field to the starting offset into the current page, where current page is selected through the value in the *C\_Page* field.

The following table describes the qTD Buffer Pointer(s) (DWords 3-7) fields.

**Table 11-80. qTD Buffer Pointer(s) (DWords 3-7)**

Bit	Description
31-12	Buffer Pointer List. Each element in the list is a 4 K page aligned physical memory address. The lower 12 bits in each pointer are reserved (except for the first one), as each memory pointer must reference the start of a 4 K page. The field <i>C_Page</i> specifies the current active pointer. When the transfer element descriptor is fetched, the starting buffer address is selected using <i>C_Page</i> (similar to an array index to

*Table continues on the next page...*

**Table 11-80. qTD Buffer Pointer(s) (DWords 3-7) (continued)**

	select an array element). If a transaction spans a 4K buffer boundary, the host controller must detect the page-span boundary in the data stream, increment C_Page and advance to the next buffer pointer in the list, and conclude the transaction through the new buffer pointer.
11-0	Current Offset (Reserved). This field is reserved in all pointers except the first one (for example Page 0). The host controller should ignore all reserved bits. For the page 0 current offset interpretation, this field is the byte offset into the current page (as selected by C_Page). The host controller is not required to write this field back when the qTD is retired. Software should ensure the Reserved fields are initialized to zero.

### 11.4.4.2.6 Queue Head

The following table shows the queue head structure layout.

**Table 11-81. Queue Head Structure Layout**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Addr

1. 04-0B: Static endpoint state.
2. These fields are used exclusively to support split transactions to USB 2.0 hubs
3. 10-2F: Transfer overlay.
4. 14-27: Transfer results.

Host Controller Read/Write

Host Controller Read Only

### 11.4.4.2.6.1 Queue Head Horizontal Link Pointer

The first DWord of a Queue Head contains a link pointer to the next data object to be processed after any required processing in this queue has been completed, as well as the control bits defined below.

This pointer may reference a queue head or one of the isochronous transfer descriptors. It must not reference a queue element transfer descriptor.

The following table describes the Queue head DWord 0 fields.

**Table 11-82. Queue Head DWord 0**

Bit	Description
31-5	Queue Head Horizontal Link Pointer (QHLP). This field contains the address of the next data object to be processed in the horizontal list and corresponds to memory address signals [31:5], respectively.
4-3	Reserved
2-1	QH/(s)iTD Select (Typ). This field indicates to the hardware whether the item referenced by the link pointer is an iTD, siTD or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are:  Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor) 11b FSTN (frame span traversal node)
0	Terminate (T). 1=Last QH (pointer is invalid). 0=Pointer is valid. If the queue head is in the context of the periodic list, a one bit in this field indicates to the host controller that this is the end of the periodic list. This bit is ignored by the host controller when the queue head is in the Asynchronous schedule. Software must ensure that queue heads reachable by the host controller always have valid horizontal link pointers.

### 11.4.4.2.6.2 Queue Head Endpoint Capabilities/Characteristics

The second and third DWords of a Queue Head specifies static information about the endpoint. This information does not change over the lifetime of the endpoint.

There are three types of information in this region:

- Endpoint Characteristics. These are the USB endpoint characteristics including addressing, maximum packet size, and endpoint speed.

- **Endpoint Capabilities.** These are adjustable parameters of the endpoint. They effect how the endpoint data stream is managed by the host controller.
- **Split Transaction Characteristics.** This data structure is used to manage full- and low-speed data streams for bulk, control, and interrupt via split transactions to USB2.0 Hub Transaction Translator. There are additional fields used for addressing the hub and scheduling the protocol transactions (for periodic).

The host controller must not modify the bits in this region.

The following table describes the Endpoint characteristics: Queue head DWord 1 fields.

**Table 11-83. Endpoint Characteristics: Queue Head DWord 1**

Bit	Description										
31-28	Nak Count Reload (RL). This field contains a value, which is used by the host controller to reload the Nak Counter field.										
27	Control Endpoint Flag (C). If the <i>QH.EPS</i> field indicates the endpoint is not a high-speed device, and the endpoint is a control endpoint, then software must set this bit to a one. Otherwise, it should always set this bit to zero.										
26-16	Maximum Packet Length. This directly corresponds to the maximum packet size of the associated endpoint ( <i>wMaxPacketSize</i> ). The maximum value this field may contain is 0x400 (1024).										
15	Head of Reclamation List Flag (H). This bit is set by System Software to mark a queue head as being the head of the reclamation list.										
14	Data Toggle Control (DTC). This bit specifies where the host controller should get the initial data toggle on an overlay transition.  0b Ignore DT bit from incoming qTD. Host controller preserves DT bit in the queue head.  1b Initial data toggle comes from incoming qTD DT bit. Host controller replaces DT bit in the queue head from the DT bit in the qTD.										
13-12	Endpoint Speed (EPS). This is the speed of the associated endpoint. Bit combinations are: <table border="1" data-bbox="310 1189 1472 1396"> <thead> <tr> <th>Value</th> <th>Meaning</th> </tr> </thead> <tbody> <tr> <td>00b</td> <td>Full-Speed (12 Mbits/sec)</td> </tr> <tr> <td>01b</td> <td>Low-Speed (1.5 Mbits/sec)</td> </tr> <tr> <td>10b</td> <td>High-Speed (480 Mbits/sec)</td> </tr> <tr> <td>11b</td> <td>Reserved</td> </tr> </tbody> </table> <p>This field must not be modified by the host controller.</p>	Value	Meaning	00b	Full-Speed (12 Mbits/sec)	01b	Low-Speed (1.5 Mbits/sec)	10b	High-Speed (480 Mbits/sec)	11b	Reserved
Value	Meaning										
00b	Full-Speed (12 Mbits/sec)										
01b	Low-Speed (1.5 Mbits/sec)										
10b	High-Speed (480 Mbits/sec)										
11b	Reserved										
11-8	Endpoint Number (Endpt). This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.										
7	Inactivate on Next Transaction (I). This bit is used by system software to request that the host controller set the Active bit to zero. See <a href="#">Rebalancing the periodic schedule</a> , for full operational details. This field is only valid when the queue head is in the Periodic Schedule and the <i>EPS</i> field indicates a Full or Low-speed endpoint. Setting this bit to one when the queue head is in the Asynchronous Schedule or the <i>EPS</i> field indicates a high-speed device yields undefined results.										
6-0	Device Address. This field selects the specific device serving as the data source or sink.										

The table below describes the Endpoint capabilities: Queue head DWord 2 field descriptions.

**Table 11-84. Endpoint Capabilities: Queue Head DWord 2**

Bit	Description
31-30	<p>High-Bandwidth Pipe Multiplier (Mult). This field is a multiplier used to key the host controller as the number of successive packets the host controller may submit to the endpoint in the current execution. The host controller makes the simplifying assumption that software properly initializes this field (regardless of location of queue head in the schedules or other run time parameters). The valid values are:</p> <p>Value Meaning</p> <p>00b Reserved. A zero in this field yields undefined results.</p> <p>01b One transaction to be issued for this endpoint per micro-frame.</p> <p>10b Two transactions to be issued for this endpoint per micro-frame.</p> <p>11b Three transactions to be issued for this endpoint per micro-frame.</p>
29-23	<p>Port Number. This field is ignored by the host controller unless the <i>EPS</i> field indicates a full- or low-speed device. The value is the port number identifier on the USB 2.0 Hub (for hub at device address <i>Hub Addr</i> below), below which the full- or low-speed device associated with this endpoint is attached. This information is used in the split-transaction protocol.</p>
22-16	<p>Hub Addr. This field is ignored by the host controller unless the <i>EPS</i> field indicates a full- or low-speed device. The value is the USB device address of the USB 2.0 Hub below which the full- or low-speed device associated with this endpoint is attached. This field is used in the split-transaction protocol.</p>
15-8	<p>Split Completion Mask (<math>\mu</math>Frame C-Mask). This field is ignored by the host controller unless the <i>EPS</i> field indicates this device is a low- or full-speed device and this queue head is in the periodic list. This field (along with the <i>Active</i> and <i>SplitX-state</i> fields) is used to determine during which micro-frames the host controller should execute a complete-split transaction. When the criteria for using this field are met, a zero value in this field has undefined behavior. This field is used by the host controller to match against the three low-order bits of the FRINDEX register. If the FRINDEX register bits decode to a position where the <math>\mu</math>Frame C- Mask field is a one, then this queue head is a candidate for transaction execution. There may be more than one bit in this mask set.</p>
7-0	<p>Interrupt Schedule Mask (<math>\mu</math>Frame S-mask). This field is used for all endpoint speeds. Software should set this field to a zero when the queue head is on the asynchronous schedule. A non-zero value in this field indicates an interrupt endpoint. The host controller uses the value of the three low-order bits of the FRINDEX register as an index into a bit position in this bit vector. If the <math>\mu</math>Frame S-mask field has a one at the indexed bit position then this queue head is a candidate for transaction execution. If the <i>EPS</i> field indicates the endpoint is a high-speed endpoint, then the transaction executed is determined by the <i>PID_Code</i> field contained in the execution area. This field is also used to support split transaction types: Interrupt (IN/OUT). This condition is true when this field is non-zero and the <i>EPS</i> field indicates this is either a full- or low-speed device. A zero value in this field, in combination with existing in the periodic frame list has undefined results.</p>

### 11.4.4.2.6.3 Transfer Overlay-Queue Head

The nine DWords in this area represent a transaction working space for the host controller. The general operational model is that the host controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, then it follows the Queue Head Horizontal Link Pointer to the next queue head. The host controller will never follow the Next Transfer Queue Element or Alternate Queue Element pointers unless it is actively attempting to advance the queue. For the duration of the transfer, the host controller keeps the incremental status of the transfer in the overlay area. When the transfer is complete, the results are written back to the original queue element.

The DWord3 of a Queue Head contains a pointer to the source qTD currently associated with the overlay. The host controller uses this pointer to write back the overlay area into the source qTD after the transfer is complete.

The following table describes the current qTD link pointer field descriptions.

**Table 11-85. Current qTD Link Pointer**

Bit	Description
31-5	Current Element Transaction Descriptor Link Pointer. This field contains the address Of the current transaction being processed in this queue and corresponds to memory address signals [31:5], respectively.
4-0	Reserved (R). These bits are ignored by the host controller when using the value as an address to write data. The actual value may vary depending on the usage.

The DWords 4-11 of a queue head are the transaction overlay area. This area has the same base structure as a Queue Element Transfer Descriptor. The queue head utilizes the reserved fields of the page pointers to implement tracking the state of split transactions.

This area is characterized as an overlay because when the queue is advanced to the next queue element, the source queue element is merged onto this area. This area serves as execution cache for the transfer.

The table below describes the Host-controller rules for bits in overlay.

**Table 11-86. Host-Controller Rules for Bits in Overlay (DWords 5, 6, 8 and 9)**

DWord	Bit	Description
5	4-1	Nak Counter (NakCnt) $\mu$ RW. This field is a counter the host controller decrements whenever a transaction for the endpoint associated with this queue head results in a Nak or Nyet response. This counter is reloaded from <i>RL</i> before a transaction is executed during the first pass of the reclamation list (relative to an Asynchronous List Restart condition). It is also loaded from <i>RL</i> during an overlay.
6	31	Data Toggle. The <i>Data Toggle Control</i> controls whether the host controller preserves this bit when an overlay operation is performed.
6	15	Interrupt On Complete (IOC). The IOC control bit is always inherited from the source qTD when the overlay operation is performed.
6	11-10	Error Counter (C_ERR). This two-bit field is copied from the qTD during the overlay and written back during queue advancement.
6	0	Ping State (P)/ERR. If the <i>EPS</i> field indicates a high-speed endpoint, then this field should be preserved during the overlay operation.
8	7-0	Split-transaction Complete-split Progress (C-prog-mask). This field is initialized to zero during any overlay. This field is used to track the progress of an interrupt split-transaction.
9	4-0	Split-transaction Frame Tag (Frame Tag). This field is initialized to zero during any overlay. This field is used to track the progress of an interrupt split-transaction.
9	11-5	S-bytes. Software must ensure that the <i>S-bytes</i> field in a <i>qTD</i> is zero before activating the <i>qTD</i> . This field is used to keep track of the number of bytes sent or received during an IN or OUT split transaction.

### 11.4.4.2.7 Periodic Frame Span Traversal Node (FSTN)

This data structure is to be used only for managing Full- and Low-speed transactions that span a Host-frame boundary.

See [Host Controller Operational Model for FSTNs](#) for full operational details. Software must not use an FSTN in the Asynchronous Schedule. An FSTN in the Asynchronous schedule results in undefined behavior. Software must not use the FSTN feature with a host controller whose USB\_HCIVERSION register indicates a revision implementation below 0096h. FSTNs are not defined for implementations before 0.96 and their use yields undefined results.

**Table 11-87. Frame Span Traversal Node Structure Layout**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Addr

Host Controller Read/Write

Host Controller Read Only

#### 11.4.4.2.7.1 FSTN Normal Path Pointer

The first DWord of an FSTN contains a link pointer to the next schedule object. This object can be of any valid periodic schedule data type.

The following table describes the FSTN normal path pointer fields.

**Table 11-88. FSTN Normal Path Pointer Field Descriptions**

Bit	Description
31-5	Normal Path Link Pointer (NPLP). This field contains the address of the next data object to be processed in the periodic list and corresponds to memory address signals [31:5], respectively.
4-3	Reserved
2-1	QH/(s)iTD/FSTN Select (Typ). This field indicates to the Host Controller whether the item referenced is a iTD/ siTD, a QH or an FSTN. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are:  Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor)

*Table continues on the next page...*

**Table 11-88. FSTN Normal Path Pointer Field Descriptions (continued)**

	11b FSTN (Frame Span Traversal Node)
0	Terminate (T). 1 = Link Pointer field is not valid. 0 = Link Pointer is valid.

#### 11.4.4.2.7.2 FSTN Back Path Link Pointer

The second DWord of an FTSN node contains a link pointer to a queue head.

If the T-bit in this pointer is zero, then this FSTN is a Save-Place indicator. Its Typ field must be set by software to indicate the target data structure is a queue head. If the T-bit in this pointer is set to one, then this FSTN is the Restore indicator. When the T-bit is one, the host controller ignores the Typ field.

The following table describes the FSTN back path link pointer fields.

**Table 11-89. FSTN Back Path Link Pointer Field Descriptions**

Bit	Description
31-5	Back Path Link Pointer (BPLP). This field contains the address of a Queue Head. This field corresponds to memory address signals [31:5], respectively.
4-3	Reserved
2-1	Typ. Software must ensure this field is set to indicate the target data structure is a Queue Head. Any other value in this field yields undefined results.
0	Terminate (T). 1=Link Pointer field is not valid (that is the host controller must not use bits [31:5] as a valid memory address). This value also indicates that this FSTN is a Restore indicator.  0=Link Pointer is valid (that is the host controller may use bits [31:5] (in combination with the CTRLDSSEGMENT register if applicable) as a valid memory address). This value also indicates that this FSTN is a Save-Place indicator.

#### 11.4.4.3 Host Operational Model

The general operational model is for the enhanced interface host controller hardware and enhanced interface host controller driver (generally referred to as system software).

Each significant operational feature of the EHCI host controller is discussed in a separate section. Each section presents the operational model requirements for the host controller hardware. Where appropriate, recommended system software operational models for features are also presented.

### 11.4.4.3.1 Host Controller Initialization

After initial power-on or HCRreset (hardware or through HCRreset bit in the USB\_USBCMD register), all of the operational registers are at their default values. After a hardware reset, only the operational registers not contained in the Auxiliary power well are at their default values.

The following table describes the default values of operational registers.

**Table 11-90. Default Values of Operational Register Space**

Operational Register	Default Value (after Reset)
USB_USBCMD	00080000h (00080B00h, if <i>Asynchronous Schedule Park Capability is one</i> )
USB_USBSTS	00001000h
USB_USBINTR	00000000h
USB_FRINDEX	00000000h
USB_CTRLDSSEGMENT	00000000h
USB_PERIODICLISTBASE	Undefined
USB_ASYNCLISTADDR	Undefined
USB_CONFIGFLAG	00000000h
USB_PORTSC1	00002000h (w/PPC set to one); 00003000h (w/PPC set to zero)

To initialize the host controller, software should perform the following steps:

- Write the appropriate value to the USB\_USBINTR register to enable the appropriate interrupts.
- Write the base address of the Periodic Frame List to the USB\_PERIODICLIST BASE register. If no work items are in the periodic schedule, all elements of the Periodic Frame List should have their T-Bits set to one.
- Write the USB\_USBCMD register to set the desired interrupt threshold, frame list size (if applicable) and turn the host controller ON through setting the Run/Stop bit.

At this point, the host controller is up and running and the port registers begin reporting device connects, and so on. System software can enumerate a port through the reset process (where the port is in the enabled state). At this point, the port is active with SOFs occurring down the enabled ports, but the schedules have not enabled. To communicate with devices through the asynchronous schedule, system software must write the USB\_ASYNCLISTADDR register with the address of a control or bulk queue head. Software must then enable the asynchronous schedule by writing one to the Asynchronous Schedule Enable bit in the USB\_USBCMD register. To communicate with devices through the periodic schedule, system software must enable the periodic schedule by writing one to the Periodic Schedule Enable bit in the USB\_USBCMD register.

**NOTE**

The schedules can be turned on before the first port is reset (and enabled).

When the USB\_USBCMD register is written, system software must ensure the appropriate bits are preserved, depending on the intended operation.

**11.4.4.3.2 Port Routing and Control**

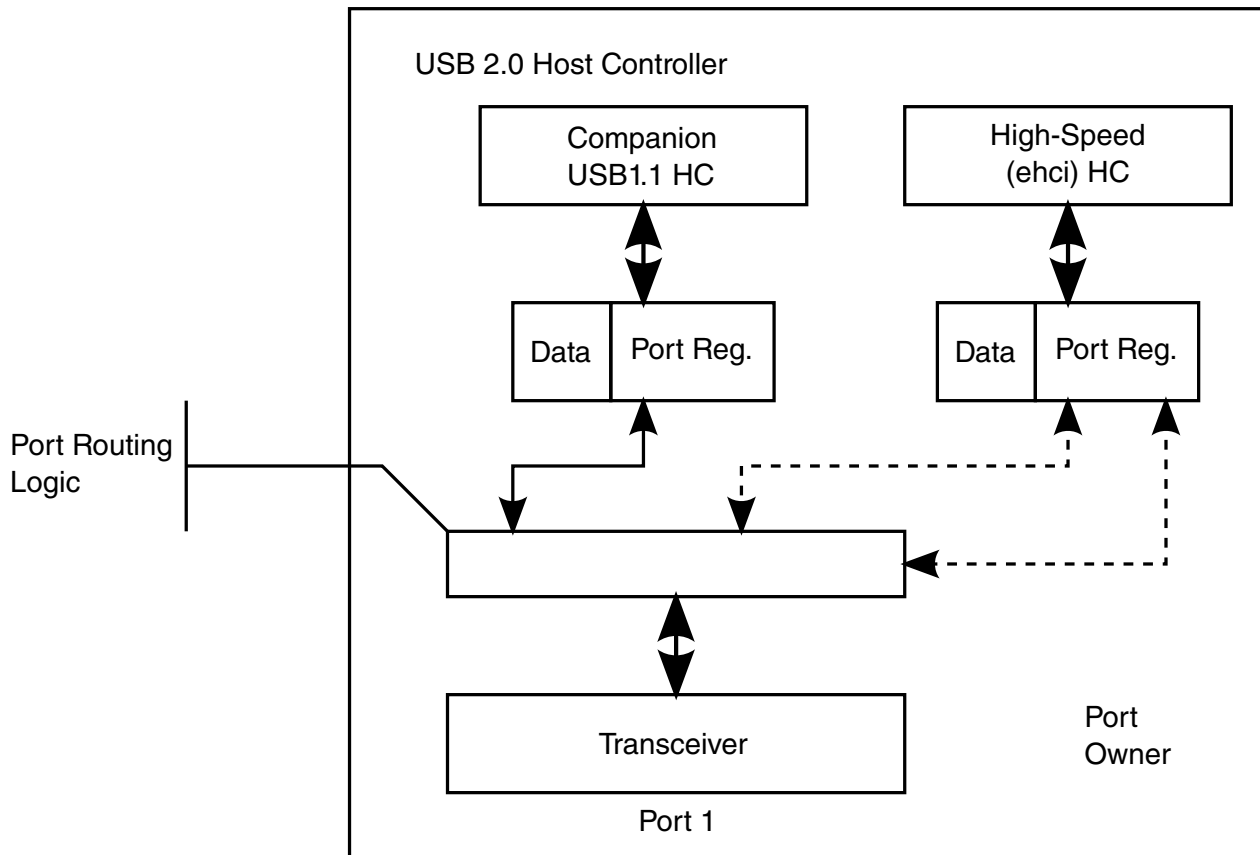

The EHCI specification defines that a USB 2.0 Host controller is comprised of one high-speed host controller, which implements the EHCI programming interface and 0 to N USB 1.1 companion host controllers.

Companion host controllers (cHCs) may be implementations of either Universal or Open host controller specifications. This configuration is used to deliver the required full USB 2.0-defined port capability; for example, Low-, Full-, and High-speed capability for every port.

**NOTE**

The USB controllers on i.MX parts do not require nor support companion controllers to support Full and Low Speed device. Full and Low Speed devices are supported within the USB controller by emulating the functionality of a high-speed HUB. Therefore, no port routing is present in the controller. Please refer to [Embedded Transaction Translator Function](#) for detail!

The following figure illustrates a simple block diagram of the port routing logic and its relationship to the high-speed and companion host controllers within a USB 2.0 host controller.

**Figure 11-63. Example USB 2.0 Host Controller Port Routing Block Diagram**

There exists one transceiver per physical port and each host controller block has its own port status and control registers. The EHCI controller has port status and control registers for every port. Each companion host controller has only the port control and status registers it is required to operate. Either the EHCI host controller or one companion host controller controls each transceiver. Routing logic lies between the transceiver, the port status and control registers.<sup>1</sup>

The port routing logic is controlled from signals originating in the EHCI host controller. The EHCI host controller has a global routing policy control field and per-port ownership control fields. The Configured Flag (CF) bit is the global routing policy control. At power-on or reset, the default routing policy is to the companion controllers (if they exist). If the system does not include a driver for the EHCI host controller and the host controller includes Companion Controllers, then the ports still work in Full- and Low-speed mode (assuming the system includes a driver for the companion controllers). In general, when the EHCI owns the ports, the companion host controllers' port registers do not see a connect indication from the transceiver. Similarly, when a companion host controller owns a port, the EHCI controller's port registers do not see a connect indication

1. The routing logic should not be implemented in the 480 MHz clock domain of the transceiver.

from the transceiver. The details on the rules for the port routing logic are described in the following sections. The USB 2.0 host controller must be implemented as a multi-function PCI device if the implementation includes companion controllers. The companion host controllers' function numbers must be less than the EHCI host controller function number. The EHCI host controller must be a larger function number with respect to the companion host controllers associated with this EHCI host controller. If a PCI device implementation contains only an EHCI controller (that is no companion controllers or other PCI functions), then the EHCI host controller must be function zero, in accordance with the PCI Specification. The N\_CC field in the Structural Parameter register (HCSPARAMS) indicates whether the controller implementation includes companion host controllers. When N\_CC has a non-zero value there exists companion host controllers. If N\_CC has a value of zero, then the host controller implementation does not include companion host controllers. If the host controller root ports are exposed to attachment of full- or low-speed devices, the ports always fails the high-speed chirp during reset and the ports are not enabled. System software can notify the user of the illegal condition. This type of implementation requires a USB 2.0 hub be connected to a root port to provide full and low-speed device connectivity.

System software uses information in the host controller capability registers to determine how the ports are routed to the companion host controllers. See .

#### **11.4.4.3.2.1 Port Routing Control through EHCI Configured (CF) Bit**

Each port in the USB 2.0 host controller are routed either to a single companion host controller or to the EHCI host controller.

The port routing logic is controlled by two mechanisms in the EHCI HC: a host controller global flag and per-port control. The Configured Flag (CF) bit, is used to globally set the policy of the routing logic. Each port register has a Port Owner control bit which allows the EHCI Driver to explicitly control the routing of individual ports. Whenever the CF bit transitions from zero to one (this transition is only available under program control) the port routing unconditionally routes all of the port registers to the EHCI HC (all Port Owner bits go to zero). While the CF-bit is one, the EHCI Driver controls individual ports' routing through the Port Owner control bit. Likewise, whenever the CF bit transitions from one to zero (as a result of Aux power application, HCRESET, or software writing zero to CF-bit), the port routing unconditionally routes all of the port registers to the appropriate companion HC. The default value for the EHCI HC's CF bit (after Aux power application or HCRESET) is zero.

The *view* of the port depends on the current owner. A Universal or Open companion host controller will see port register bits consistent with the appropriate specification. Port bit definitions that are required for EHCI host controllers are not visible to companion host controllers.

The following table summarizes the default routing for all the ports, based on the value of the EHCI HC's CF bit.

**Table 11-91. Default Port Routing Depending on EHCI HC CF Bit**

HS CF Bit	Default Port Ownership	Explanation
0B	Companion HCs	The companion host controllers own the ports and only Full- and Low-speed devices are supported in the system. The exact port assignments are implementation dependent. The ports behave only as Full- and Low-speed ports in this configuration
1B	EHCI HC	The EHCI host controller has default ownership over all of the ports. The routing logic inhibits device connect events from reaching the companion HCs' port status and control registers when the port owner is the EHCI HC. The EHCI HC has access to the additional port status and control bits defined in this specification (see ). The EHCI HC can temporarily release control of the port to a companion HC by setting the <i>PortOwner</i> bit in the PORTSC1 register to one.

#### 11.4.4.3.2 Port Routing Control through PortOwner and Disconnect Event

Manipulating the port routing through the CF-bit is an extreme process and not intended to be used during normal operation.

The normal mode of port ownership transferal is on the granularity of individual ports using the Port Owner bit in the EHCI HC's USB\_PORTSC1 register (for hand-offs from EHCI to companion host controllers). Individual port ownership is returned to the EHCI controller when the port registers a device disconnect. When the disconnect is detected, the port routing logic immediately returns the port ownership to the EHCI controller. The companion host controller port register detects the device disconnect and operates normally.

Under normal operating conditions (assuming all HC drivers loaded and operational and the EHCI *CF-bit* is set to one), the typical port enumeration sequence proceeds as illustrated below:

- Initial condition is that EHCI is port owner. A device is connected causing the port to detect a connect, set the port connect change bit and issue a port-change interrupt (if enabled).
- EHCI Driver identifies the port with the new connect change bit asserted and sends a change report to the hub driver. Hub driver issues a GetPortStatus() request and

identifies the connect change. It then issues a request to clear the connect change, followed by a request to reset and enable the port.

- When the EHCI Driver receives the request to reset and enable the port, it first checks the value reported by the LineStatus bits in the USB\_PORTSC1 register. If they indicate the attached device is a full-speed device (for example, D+ is asserted), then the EHCI Driver sets the PortReset control bit to one (and sets the PortEnable bit to zero) which begins the reset-process. Software times the duration of the reset, then terminates reset signaling by writing zero to the port reset bit. The reset process is actually complete when software reads zero in the PortReset bit. The EHCI Driver checks the PortOwner bit in the USB\_PORTSC1 register. If set to one, the connected device is a high-speed device and EHCI Driver (root hub emulator) issues a change report to the hub driver and the hub driver continues to enumerate the attached device.
- At the time the EHCI Driver receives the port reset and enable request the LineStatus bits might indicate a low-speed device. Additionally, when the port reset process is complete, the PortEnable field may indicate that a full-speed device is attached. In either case the EHCI driver sets the PortOwner bit in the USB\_PORTSC1 register to one to release port ownership to a companion host controller.
- When the EHCI Driver sets PortOwner bit to one, the port routing logic makes the connection state of the transceiver available to the companion host controller port register and removes the connection state from the EHCI HC port. The EHCI USB\_PORTSC1 register observes and reports a disconnect event through the disconnect change bit. The EHCI Driver detects the connection status change (either by polling or by port change interrupt) and then sends a change report to the hub driver. When the hub driver requests that port-state, the EHCI Driver responds with a reset complete change set to one, a connect change set to one and a connect status set to zero. This information is derived directly from the EHCI port register. This allows the hub driver to assume the device was disconnected during reset. It acknowledges the change bits and wait for the next change event. While the EHCI controller does not own the port, it simply remains in a state where the port reports no device connected. The device-connect evaluation circuitry of the companion HC activates and detects the device, the companion Driver detects the connection and enumerates the port.

When a port is routed to a companion HC, it remains under the control of the companion HC until the device is disconnected from the root port (ignoring for now the scenario where EHCI's CF-bit transitions from 1b to 0b). When a disconnect occurs, the disconnect event is detected by both the companion HC port control and the EHCI port ownership control. On the event, the port ownership is returned immediately to the EHCI controller. The companion HC stack detects the disconnect and acknowledges as it would in an ordinary standalone implementation. Subsequent connects is detected by the EHCI port register and the process repeats.

### 11.4.4.3.2.3 Example Port Routing State Machine

The following figure illustrates an example of how the port ownership should be managed. The following sections describe the entry conditions to each state.

**Figure 11-64. Port Owner Handoff State Machine**

#### 11.4.4.3.2.3.1 EHCI HC Owner

Entry to this state occurs when one of the following events occur:

- When the EHCI HC's Configure Flag (CF) bit in the USB\_CONFIGFLAG register transitions from zero to one. This signals the fact that the system has a host controller driver for the EHCI HC and that all ports in the USB 2.0 host controller must default route to the EHCI controller.
- When the port is owned by a companion HC and the device is disconnected from the port. The EHCI port routing control logic is notified of the disconnect, and returns port routing to the EHCI controller. The connection state of the companion HC goes immediately to the disconnected state (with appropriate side effect to connect change, enable and enable change). The companion HC driver acknowledges the disconnect by setting the connect status change bit to zero. This allows the companion HC's driver to interact with the port completely through the disconnect process.
- When system software writes zero to the PortOwner bit in the USB\_PORTSC1 register. This allows software to take ownership of a port from a companion host controller. When this occurs, the routing logic to the companion HC effectively signals a disconnect to the companion HC's port status and control register.

#### 11.4.4.3.2.3.2 Companion HC Owner

Entry to this state occurs whenever one of the following events occur:

- When the PortOwner field transitions from zero to one.
- When the HS-mode HC's Configure Flag (CF) is equal to zero.

On entry to this state, the routing logic allows the companion HC port register to detect a device connect. Normal port enumeration proceeds.

#### 11.4.4.3.2.4 Port Power

The Port Power Control (PPC) bit in the USB\_HCSPARAMS register indicates whether the USB 2.0 host controller has port power control (see ).

When this bit is zero, then the host controller does not support software control of port power switches. When in this configuration, the port power is always available and the companion host controllers must implement functionality consistent with port power always on. When the *PPC* bit is one, then the host controller implementation includes port power switches. Each available switch has an output enable, which is referred to in this discussion as PortPowerOutputEnable (PPE). PPE is controlled based on the state of the combination bits PPC bit, EHCI Configured (CF)-bit and individual Port Power (PP) bits.

The following table describes the summary behavioral model.

**Table 11-92. Port Power Enable Control Rules**

CF	CHC <sup>1</sup> (PP)	EHC <sup>2</sup> (PP)	Owner	PPE <sup>3</sup>	Description
0	0	X	CHC	0	When the EHCI controller is not configured, the port is owned by the companion host controller. When the companion HC's port power select is off, then the port power is off.
0	1	X	CHC	1	Similar to previous entry. When the companion HC's port power select is on, then the port power is on.
1	0	0	CHC	0	Port owner has port power turned off, the power to port is off.
1	0	0	EHC	0	Port owner has port power turned off, the power to port is off.
1	0	1	EHC	1	Port owner has port power on, so power to port is on.
1	0	1	CHC	1	If either HC has port power turned on, the power to the port is on.

*Table continues on the next page...*

**Table 11-92. Port Power Enable Control Rules (continued)**

1	1	0	EHC	1	If either HC has port power turned on, the power to the port is on.
1	1	0	CHC	1	Port owner has port power on, so power to port is on.
1	1	1	CHC	1	Port owner has port power on, so power to port is on.
1	1	1	EHC	1	Port owner has port power on, so power to port is on.

1. CHC (Companion Host Controller).
2. EHC (EHCI Host Controller).
3. PPE (Port Power Enable). This bit actually turns on the port power switch (if one exists).

### 11.4.4.3.2.5 Port Reporting Over-Current

Host controllers are by definition power providers on USB. Whether the ports are considered high- or low-powered is a platform implementation issue. Each EHCI USB\_PORTSC1 register has an over-current status and over-current change bit.

The functionality of these bits are specified in the USB Specification Revision 2.0.

The over current detection and limiting logic usually resides outside the host controller logic. This logic may be associated with one or more ports. When this logic detects an over-current condition it is made available to both the companion and EHCI ports. The effect of an over-current status on a companion host controller port is beyond the scope of this document.

The over-current condition effects the following bits in the USB\_PORTSC1 register on the EHCI port:

- Over-current Active bits are set to one. When the over-current condition goes away, the Over-current Active bit transitions from one to zero.
- Over-current Change bits are set to one. On every transition of the Over-current Active bit the host controller sets the Over-current Change bit to one. Software sets the Over-current Change bit to zero by writing one to this bit.
- Port Enabled/Disabled bit is set to zero. When this change bit gets set to one, then the Port Change Detect bit in the USB\_USBSTS register is set to one.
- Port Power (PP) bits may optionally be set to zero. There is no requirement in USB that a power provider shut off power in an over current condition. It is sufficient to limit the current and leave power applied. When the Over-current Change bit transitions from zero to one, the host controller also sets the Port Change Detect bit in the USB\_USBSTS register to one. In addition, if the Port Change Interrupt Enable bit in the USB\_USBINTR register is one, then the host controller issues an interrupt to the system. Refer to [Table 11-93](#) for summary behavior for over-current detection

when the host controller is halted (suspended from a device component point of view).

### 11.4.4.3.3 Suspend/Resume-Host Operational Model

The EHCI host controller provides an equivalent suspend and resume model as that defined for individual ports in a USB 2.0 Hub.

Control mechanisms are provided to allow system software to suspend and resume individual ports. The mechanisms allow the individual ports to be resumed completely through software initiation. Other control mechanisms are provided to parameterize the host controller's response (or sensitivity) to external resume events. In this discussion, host-initiated, or software initiated resumes are called Resume Events/Actions. Bus-initiated resume events are called wake-up events. The classes of wake-up events are:

- Remote-wake-up enabled device asserts resume signaling. In similar kind to USB 2.0 Hubs, EHCI controllers must always respond to explicit device resume signaling and wake-up the system (if necessary).
- Port connect and disconnect and over-current events. Sensitivity to these events can be turned on or off by using the per-port control bits in the USB\_PORTSC1 registers.

Selective suspend is a feature supported by every USB\_PORTSC1 register. It is used to place specific ports into a suspend mode. This feature is used as a functional component for implementing the appropriate power management policy implemented in a particular operating system. When system software intends to suspend the entire bus, it should selectively suspend all enabled ports, then shut off the host controller by setting the Run/Stop bit in the USB\_USBCMD register to zero. The EHCI sub-block can then be placed into a lower device state through the PCI power management interface (see Appendix A, Enhanced Host Controller Interface Specification for Universal Serial Bus, Revision 0.95, November 2000, Intel Corporation. <http://www.intel.com>).

When a wake event occurs, the system resumes operation and system software eventually set the Run/Stop bit to one and resume the suspended ports. Software must not set the Run/Stop bit to one until it is confirmed that the clock to the host controller is stable. This is usually confirmed in a system implementation in that all of the clocks in the system are stable before the ARM platform is restarted. So, by definition, if software is running, clocks in the system are stable and the Run/Stop bit in the USB\_USBCMD register can be set to one. Minimum system software delays are also defined in the PCI Power Management Specification. Refer to PCI Power Management Specification for more information.

### 11.4.4.3.3.1 Port Suspend/Resume

System software places individual ports into suspend mode by writing one into the appropriate USB\_PORTSC1 Suspend bit. Software must only set the Suspend bit when the port is in the enabled state (Port Enabled bit is one) and the EHCI is the port owner (PortOwner bit is zero).

The host controller may evaluate the Suspend bit immediately or wait until a micro-frame or frame boundary occurs. If evaluated immediately, the port is not suspended until the current transaction (if one is executing) completes. Therefore, there may be several micro-frames of activity on the port until the host controller evaluates the Suspend bit. The host controller must evaluate the Suspend bit at least every frame boundary.

System software can initiate a resume on a selectively suspended port by writing one to the Force Port Resume bit. Software should not attempt to resume a port unless the port reports that it is in the suspended state (see ). If system software sets Force Port Resume bit to one when the port is not in the suspended state, the resulting behavior is undefined. In order to assure proper USB device operation, software must wait for at least 10 ms after a port indicates that it is suspended (Suspend bit is one) before initiating a port resume through the Force Port Resume bit. When Force Port Resume bit is one, the host controller sends resume signaling down the port. System software times the duration of the resume (nominally 20 ms) then sets the Force Port Resume bit to zero. When the host controller receives the write to transition Force Port Resume to zero, it completes the resume sequence as defined in the USB specification, and sets both the Force Port Resume and Suspend bits to zero. Software-initiated port resumes do not affect the Port Change Detect bit in the USB\_USBSTS register nor do they cause an interrupt if the Port Change Interrupt Enable bit in the USB\_USBINTR register is one. An external USB event may also initiate a resume. The wake events are defined above. When a wake event occurs on a suspended port, the resume signaling is detected by the port and the resume is reflected downstream within 100  $\mu$ sec. The port's Force Port Resume bit is set to one and the Port Change Detect bit in the USB\_USBSTS register is set to one. If the Port Change Interrupt Enable bit in the USB\_USBINTR register is one the host controller issues a hardware interrupt.

System software observes the resume event on the port, delays a port resume time (nominally 20 ms), then terminates the resume sequence by writing zero to the Force Port Resume bit in the port. The host controller receives the write of zero to Force Port Resume, terminates the resume sequence and sets Force Port Resume and Suspend port bits to zero. Software can determine that the port is enabled (not suspended) by sampling the USB\_PORTSC1 register and observing that the Suspend and Force Port Resume bits are zero. Software must ensure that the host controller is running (that is HCHalted bit in the USB\_USBSTS register is zero), before terminating a resume by writing zero to a

port's Force Port Resume bit. If HCHalted is one when Force Port Resume is set to zero, then SOFs do not occur down the enabled port and the device returns to suspend mode in a maximum of 10 msec.

The table below summarizes the wake-up events. Whenever a resume event is detected, the Port Change Detect bit in the USB\_USBSTS register is set to one. If the Port Change Interrupt Enable bit is one in the USB\_USBINTR register, the host controller generates an interrupt on the resume event. Software acknowledges the resume event interrupt by clearing the Port Change Detect status bit in the USB\_USBSTS register.

**Table 11-93. Behavior During Wake-up Events**

Port Status and Signaling Type	Signaled Port Response	Device State	
		D0	Not D0
Port disabled, resume K-State received	No Effect	N/A	N/A
Port suspended, resume K-State received	Resume reflected downstream on signaled port. Force Port Resume status bit in USB_PORTSC1 register is set to one. Port Change Detect bit in USB_USBSTS register set to one.	[1], [2]	[2]
Port is enabled, disabled or suspended, and the port's WKDSCNNT_E bit is one. A disconnect is detected.	Depending in the initial port state, the USB_PORTSC1 Connected Enable status bits are set to zero, and the Connect Change status bit is set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [2]	[2]
Port is enabled, disabled or suspended, and the port's WKDSCNNT_E bit is zero. A disconnect is detected.	Depending on the initial port state, the USB_PORTSC1 Connect and Enable status bits are set to zero, and the Connect Change status bit is set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [3]	[3]
Port is not connected and the port's WKCNTNT_E bit is one. A connect is detected.	USB_PORTSC1 Connect Status and Connect Status Change bits are set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [2]	[2]
Port is not connected and the port's WKCNTNT_E bit is zero. A connect is detected.	USB_PORTSC1 Connect Status and Connect Status Change bits are set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [3]	[3]
Port is connected and the port's WKOC_E bit is one. An over-current condition occurs.	USB_PORTSC1 Over-current Active, Over-current Change bits are set to one. If Port Enable/Disable bit is one, it is set to zero. Port Change Detect bit in the USB_USBSTS register is set to one	[1], [2]	[2]
Port is connected and the port's WKOC_E bit is zero. An over-current condition occurs.	USB_PORTSC1 Over-current Active, Over-current Change bits are set to one. If Port Enable/Disable bit is one, it is set to zero. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [3]	[3]

[1] Hardware interrupt issued if Port Change Interrupt Enable bit in the USB\_USBINTR register is one.

[2] PME# asserted if enabled (Note: PME Status must always be set to one).

[3] PME# not asserted.

#### 11.4.4.3.4 Schedule Traversal Rules

The host controller executes transactions for devices using a simple, shared-memory schedule.

The schedule is comprised of a few data structures, organized into two distinct lists. The data structures are designed to provide the maximum flexibility required by USB, minimize memory traffic and hardware / software complexity.

System software maintains two schedules for the host controller: a periodic schedule and an asynchronous schedule. The root of the periodic schedule is the `USB_PERIODICLISTBASE` register (see [/](#)). The `USB_PERIODICLISTBASE` register is the physical memory base address of the periodic frame list. The periodic frame list is an array of physical memory pointers. The objects referenced from the frame list must be valid schedule data structures as defined in [Host Data Structures](#). In each micro-frame, if the periodic schedule is enabled (see [Periodic scheduling threshold](#)) then the host controller must execute from the periodic schedule before executing from the asynchronous schedule. It only executes from the asynchronous schedule after it encounters the end of the periodic schedule. The host controller traverses the periodic schedule by constructing an array offset reference from the `USB_PERIODICLISTBASE` and the `USB_FRINDEX` registers (see the following figure). It fetches the element and begins traversing the graph of linked schedule data structures.

The end of the periodic schedule is identified by a next link pointer of a schedule data structure having its T-bit set to one. When the host controller encounters a T-Bit set to one during a horizontal traversal of the periodic list, it interprets this as an End-Of-Periodic-List mark. This causes the host controller to cease working on the periodic schedule and transitions immediately to traversing the asynchronous schedule. After the transition, the host controller executes from the asynchronous schedule until the end of the micro-frame.

The following figure illustrates the derivation of pointer into frame list array.

**Figure 11-65. Derivation of Pointer into Frame List Array**

When the host controller determines that it is the time to execute from the asynchronous list, it uses the operational register USB\_ASYNC\_LIST\_ADDR to access the asynchronous schedule, see the figure below.

**Figure 11-66. General Format of Asynchronous Schedule List**

The USB\_ASYNC\_LIST\_ADDR register contains a physical memory pointer to the next queue head. When the host controller makes a transition to executing the asynchronous schedule, it begins by reading the queue head referenced by the USB\_ASYNC\_LIST\_ADDR register. Software must set queue head horizontal pointer T-bits to zero for queue heads in the asynchronous schedule. See [Asynchronous Schedule](#) for complete operational details.

#### 11.4.4.3.4.1 Example - Preserving Micro-Frame Integrity

One of the requirements of a USB host controller is to maintain Frame Integrity. This means that the HC must preserve the micro-frame boundaries.

For example, SOF packets must be generated on time (within the specified allowable jitter), and High-speed EOF1,2 thresholds must be enforced. The end of micro-frame timing points EOF1 and EOF2 are clearly defined in the USB Specification Revision 2.0. One implication of this responsibility is that the HC must ensure that it does not start transactions that do not complete before the end of the micro-frame. More precisely, no transactions should be started by the host controller, which do not complete in their entirety before the EOF1 point. In order to enforce this rule, the host controller must check each transaction before it starts to ensure that it completes before the end of the micro-frame.

So, what exactly needs to be involved in this check? Fundamentally, the transaction data payload, plus bit stuffing, plus transaction overhead must be taken into consideration. It is possible to be extremely accurate on how much time the next transaction takes. Take OUTs for an example. The host controller must fetch all of the OUT data from memory in order to send it onto the USB bus. A host controller implementation could pre-fetch all of the OUT data, and pre-compute the actual number of bits in the token and data packets. In addition, the system knows the depth of the target endpoint, so it could closely estimate turnaround time for handshake. In addition, the host controller knows the size of a handshake packet. Pre-computing effects of bit stuffing and summing up the other overhead numbers can allow the host controller to know exactly whether there is enough bus time, before EOF1 to complete the OUT transaction. To accomplish this particular approach takes an inordinate amount of time and hardware complexity.

The alternative is to make a reasonable guess whether the next transaction can be started. An example approximation algorithm is described below. This example algorithm relies on the EHCI policy that periodic transactions are scheduled first in the micro-frame. It is a reasonable assumption that software never over-commits the micro-frame to periodic transactions greater than the specification allowable 80%. In the available remaining 20% bandwidth, the host controller has some ability (in this example) to decide whether or not to execute a transaction. The result of this algorithm is that sometimes, under some circumstances a transaction is not executed that could have been executed. However, under all circumstances, a transaction is never started unless there is enough time in the frame to complete the transaction.

#### 11.4.4.3.4.1.1 Transaction Fit - A Best-Fit Approximation Algorithm

A curve is calculated which represents the latest start time for every packet size, at which software schedules the start of a periodic transaction.

This curve is the 80% bandwidth curve. Another curve is calculated which is the absolute, latest permitted start time for every packet size. This curve represents the absolute latest time, that a transaction of each packet size can be started and completed, in the micro-frame. A plot of these two curves are illustrated in [Figure 11-67](#). The plot Y-axis represents the number of byte-times left in a frame.

The space between the 80% and the Last Start plots is bandwidth reclamation area. In this algorithm the host controller may skip transactions during this time if it is prudent.

The Best-Fit Approximation method plots a function ( $f(x)$ ) between the 80% and Last Start curves. The function  $f(x)$  adds a constant to every transaction's maximum packet size and the result compared with the number of bytes left in the frame. The constant represents an approximation of the effects of bit stuffing and protocol overhead. The host controller starts transactions whose results land above the function curve. The host controller will not start transactions whose results land below the function curve.

The following figure illustrates the Best-Fit Approximation.

**Figure 11-67. Best Fit Approximation**

The LastStart line was calculated in this example to assume the absolute worst-case bus overhead per transaction. The particular transaction used is a start-split, zero-length OUT transaction with a handshake. Summaries of the component parts are listed in the table below. The component times were derived from the protocol timings defined in the USB Specification Revision 2.0.

**Table 11-94. Example Worse-case Transaction Timing Components**

Component	Bit time	Byte Time	Explanation
Split Token	76	9.5	Split token as defined in USB core specification. Includes sync, token, eop, and so on.
Host 2 Host IPG	88	11	Number of bit times required between consecutive host packets.
Token	67	8.375	Token as defined in USB core specification. Includes sync, token, eop, and so on.
Host 2 Host IPG	88	11	Token as defined in USB core specification. Includes sync, token, eop, and so on.
Data Packet (0 data bytes)	66.7	8.34	Zero-length data packet. Includes sync, PID, crc16, eop, and so on.
Turnaround time	721	90.125	Time for packet initiator (Host) to see the beginning of a response to a transmitted packet.
Handshake packet	48	6	Handshake packet as defined in USB core specification. Includes sync, PID, eop, and so on.
		144	Total

The exact details of the function (f(x)) are up to the particular implementation. However, it should be obvious that the goal is to minimize the area under the curve between the approximation function and the Last Start curve, without dipping below the LastStart line, while at the same time keeping the check as simple as possible for hardware implementation. The f(x) in [Figure 11-67](#) was constructed using the following pseudo-code test on each transaction size data point. This algorithm assumes that the host controller keeps track of the remaining bits in the frame.

```

Algorithm CheckTransactionWillFit (MaximumPacketSize, HC_BytesLeftInFrame)
Begin
Local Temp = MaximumPacketSize + 192
Local rvalue = TRUE
If MaximumPacketSize >= 128 then
    Temp += 128
End If
If Temp > HC_BytesLeftInFrame then
    Rvalue = FALSE
End If
Return rvalue
End
    
```

This algorithm takes two inputs, the current maximum packet size of the transaction and the hardware counter of the number of bytes left in the current micro-frame. It unconditionally adds a simple constant of 192 to the maximum packet size to account for a first-order effect of transaction overhead and bit stuffing. If the transaction size is greater than or equal to 128 bytes, then an additional constant of 128 is added to the

running sum to account for the additional worst-case bit stuffing of payloads larger than 128. An inflection point was inserted at 128 because the  $f(x)$  plot was getting close to the LastStart line.

#### 11.4.4.3.5 Periodic Schedule Frame Boundaries vs Bus Frame Boundaries

The USB Specification Revision 2.0 requires that the frame boundaries (SOF frame number changes) of the high-speed bus and the full- and low-speed bus(s) below USB 2.0 Hubs be strictly aligned.

Super-imposed on this requirement is that USB 2.0 Hubs manage full- and low-speed transactions through a micro-frame pipeline (see start- (SS) and complete- (CS) splits illustrated in the following figure). A simple, direct projection of the frame boundary model into the host controller interface schedule architecture creates tension (complexity for both hardware and software) between the frame boundaries and the scheduling mechanisms required to service the full- and low-speed transaction translator periodic pipelines.

**Figure 11-68. Frame Boundary Relationship between HS bus and FS/LS Bus**

The simple projection, as the above figure illustrates, introduces frame-boundary wrap conditions for scheduling on both the beginning and end of a frame. In order to reduce the complexity for hardware and software, the host controller is required to implement one micro-frame phase shift for its view of frame boundaries. The phase shift eliminates the beginning of frame and frame-wrap scheduling boundary conditions.

The implementation of this phase shift requires that the host controller use one register value for accessing the periodic frame list and another value for the frame number value included in the SOF token. These two values are separate, but tightly coupled. The periodic frame list is accessed through the Frame List Index Register (USB\_FRINDEX) documented in and initially illustrated in [Schedule Traversal Rules](#). Bits FRINDEX[2:0], represent the micro-frame number. The SOF value is coupled to the value of FRINDEX[13:3]. Both FRINDEX[13:3] and the SOF value are increment based on FRINDEX[2:0]. It is required that the SOF value be delayed from the FRINDEX value by one micro-frame. The one micro-frame delay yields host controller periodic schedule

and bus frame boundary relationship as illustrated in the following figure. This adjustment allows software to trivially schedule the periodic start and complete-split transactions for full- and low-speed periodic endpoints, using the natural alignment of the periodic schedule interface. The reasons for selecting this phase-shift are beyond the scope of this specification.

The following figure illustrates how periodic schedule data structures relate to schedule frame boundaries and bus frame boundaries. To aid the presentation, two terms are defined: The host controller's view of the 1 msec boundaries is called H-Frames. The high-speed bus's view of the 1 msec boundaries is called B-Frames.

**Figure 11-69. Relationship of Periodic Schedule Frame Boundaries to Bus Frame Boundaries**

H-Frame boundaries for the host controller correspond to increments of FRINDEX[13:3]. Micro-frame numbers for the H-Frame are tracked by FRINDEX[2:0]. B-Frame boundaries are visible on the high-speed bus through changes in the SOF token's frame number. Micro-frame numbers on the high-speed bus are only derived from the SOF token's frame number (that is the high-speed bus sees eight SOFs with the same frame number value). H-Frames and B-Frames have the fixed relationship (that is B-Frames lag H-Frames by one micro-frame time) illustrated in the figure above. The host controller's periodic schedule is naturally aligned to H-Frames. Software schedules transactions for full- and low-speed periodic endpoints relative the H-Frames. The result is these transactions execute on the high-speed bus at exactly the right time for the USB 2.0 Hub periodic pipeline. As described in , the SOF Value can be implemented as a shadow register (in this example, called SOFV), which lags the FRINDEX register bits [13:3] by one micro-frame count. This lag behavior can be accomplished by incrementing FRINDEX[13:3] based on carry-out on the 7 to 0 increment of FRINDEX[2:0] and incrementing SOFV based on the transition of 0 to 1 of FRINDEX[2:0].

Software is allowed to write to FRINDEX. provides the requirements that software should adhere when writing a new value in FRINDEX.

The table below illustrates the required relationship between the value of FRINDEX and the value of SOFV.

**Table 11-95. Operation of FRINDEX and SOFV (SOF Value Register)**

#### 11.4.4.3.6 Periodic Schedule

The periodic schedule traversal is enabled or disabled through the Periodic Schedule Enable bit in the USB\_USBCMD register.

If the Periodic Schedule Enable bit is set to zero, then the host controller simply does not try to access the periodic frame list through the USB\_PERIODICLISTBASE register. Likewise, when the Periodic Schedule Enable bit is one, then the host controller does use the USB\_PERIODICLISTBASE register to traverse the periodic schedule. The host controller will not react to modifications to the Periodic Schedule Enable immediately. In order to eliminate conflicts with split transactions, the host controller evaluates the Periodic Schedule Enable bit only when FRINDEX[2:0] is zero. System software must not disable the periodic schedule if the schedule contains an active split transaction work item that spans the 000b micro-frame. These work items must be removed from the schedule before the Periodic Schedule Enable bit is written to zero. The Periodic Schedule Status bit in the USB\_USBSTS register indicates status of the periodic schedule. System software enables (or disables) the periodic schedule by writing one (or zero) to the Periodic Schedule Enable bit in the USB\_USBCMD register. Software then can poll the Periodic Schedule Status bit to determine when the periodic schedule has

made the desired transition. Software must not modify the Periodic Schedule Enable bit unless the value of the Periodic Schedule Enable bit equals that of the Periodic Schedule Status bit.

The periodic schedule is used to manage all isochronous and interrupt transfer streams. The base of the periodic schedule is the periodic frame list. Software links schedule data structures to the periodic frame list to produce a graph of scheduled data structures. The graph represents an appropriate sequence of transactions on the

The following figure illustrates isochronous transfers (using iTDs and siTDs) with a period of one are linked directly to the periodic frame list. Interrupt transfers (are managed with queue heads) and isochronous streams with periods other than one are linked following the period-one iTD/siTDs. Interrupt queue heads are linked into the frame list ordered by poll rate. Longer poll rates are linked first (for example, closest to the periodic frame list), followed by shorter poll rates, with queue heads with a poll rate of one, on the very end.

Figure 11-70. Example Periodic Schedule

### 11.4.4.3.7 Managing Isochronous Transfers Using iTDs

The structure of an iTD is presented in [Isochronous \(High-Speed\) Transfer Descriptor \(iTD\)](#). The four distinct sections to an iTD:

- The first field is the Next Link Pointer. This field is for schedule linkage purposes only.
- Transaction description array. This area is an eight-element array. Each element represents control and status information for one micro-frame's worth of transactions for a single high-speed isochronous endpoint.
- The buffer page pointer array is a 7-element array of physical memory pointers to data buffers. These are 4 K aligned pointers to physical memory.
- Endpoint capabilities. This area utilizes the unused low-order 12 bits of the buffer page pointer array. The fields in this area are used across all transactions executed for this iTD, including endpoint addressing, transfer direction, maximum packet size and high-bandwidth multiplier.

#### 11.4.4.3.7.1 Host Controller Operational Model for iTDs

The host controller uses FRINDEX register bits [12:3] to index into the periodic frame list. This means that the host controller visits each frame list element eight consecutive times before incrementing to the next periodic frame list element. Each iTD contains eight transaction descriptions, which map directly to FRINDEX register bits [2:0]. Therefore, each transaction descriptor corresponds to one micro-frame. Each iTD can span 8 micro-frames worth of transactions.

When the host controller fetches an iTD, it uses FRINDEX register bits [2:0] to index into the transaction description array.

If the active bit in the Status field of the indexed transaction description is set to zero, the host controller ignores the iTD and follows the Next pointer to the next schedule data structure.

When the indexed active bit is one, the host controller continues to parse the iTD. It stores the indexed transaction description and the general endpoint information (device address, endpoint number, maximum packet size, and so on.). It also uses the Page Select (PG) field to index the buffer pointer array, storing the selected buffer pointer and the next sequential buffer pointer. For example, if PG field is 0, then the host controller stores Page 0 and Page 1.

The host controller constructs a physical data buffer address by concatenating the current buffer pointer (as selected using the current transaction description's PG field) and the transaction description's Transaction Offset field. The host controller uses the endpoint addressing information and I/O-bit to execute a transaction to the appropriate endpoint.

When the transaction is complete, the host controller clears the active bit and writes back any additional status information to the Status field in the currently selected transaction description.

The data buffer associated with the iTD must be virtually contiguous memory. Seven page pointers are provided to support eight high-bandwidth transactions regardless of the starting packet's offset alignment into the first page. A starting buffer pointer (physical memory address) is constructed by concatenating the page pointer (for example, page 0 pointer) selected by the active transaction descriptions' PG (for example, value: 00B) field with the transaction offset field. As the transaction moves data, the host controller must detect when an increment of the current buffer pointer crosses a page boundary. When this occurs the host controller simply replaces the current buffer pointer's page portion with the next page pointer (for example, page 1 pointer) and continues to move data. The size of each bus transaction is determined by the value in the Maximum Packet Size field. An iTD supports high-bandwidth pipes through the Mult (multiplier) field. When the Mult field is 1, 2, or 3, the host controller executes the specified number of Maximum Packet sized bus transactions for the endpoint in the current micro-frame. In other words, the Mult field represents a transaction count for the endpoint in the current micro-frame. If the Mult field is zero, the operation of the host controller is undefined. The transfer description is used to service all transactions indicated by the Mult field.

For OUT transfers, the value of the Transaction X Length field represents the total bytes to be sent during the micro-frame. The Mult field must be set by software to be consistent with Transaction X Length and Maximum Packet Size. The host controller sends the bytes in Maximum Packet Size'd portions. After each transaction, the host controller decrements its local copy of Transaction X Length by Maximum Packet Size. The number of bytes the host controller sends is always Maximum Packet Size or Transaction X Length, whichever is less. The host controller advances the transfer state in the transfer description, updates the appropriate record in the iTD and moves to the next schedule data structure. The maximum sized transaction supported is 3 x 1024 bytes.

For IN transfers, the host controller issues Mult transactions. It is assumed that software has properly initialized the iTD to accommodate all of the possible data. During each IN transaction, the host controller must use Maximum Packet Size to detect packet babble errors. The host controller keeps the sum of bytes received in the Transaction X Length field. After all transactions for the endpoint have completed for the micro-frame, Transaction X Length contains the total bytes received. If the final value of Transaction X Length is less than the value of Maximum Packet Size, then less data than was allowed for was received from the associated endpoint. This short packet condition does not set the USBINT bit in the USB\_USBSTS register to one. The host controller will not detect this condition. If the device sends more than Transaction X Length or Maximum Packet Size bytes (whichever is less), then the host controller sets the Babble Detected bit to one and set the Active bit to zero. Note, that the host controller is not required to update the

iTD field Transaction X Length in this error scenario. If the Mult field is greater than one, then the host controller automatically executes the value of Mult transactions. The host controller will not execute all Mult transactions if:

- The endpoint is an OUT and Transaction X Length goes to zero before all the Mult transactions have executed (ran out of data), or
- The endpoint is an IN and the endpoint delivers a short packet, or an error occurs on a transaction before Mult transactions have been executed. The end of micro-frame may occur before all of the transaction opportunities have been executed. When this happens, the transfer state of the transfer description is advanced to reflect the progress that was made, the result written back to the iTD and the host controller proceeds to processing the next micro-frame. Refer to Appendix D for a table summary of the host controller required behavior for all the high-bandwidth transaction cases.

#### 11.4.4.3.7.2 Software Operational Model for iTDs

A client buffer request to an isochronous endpoint may span 1 to N micro-frames. When N is larger than one, system software may have to use multiple iTDs to read or write data with the buffer (if N is larger than eight, it must use more than one iTD).

The following figure illustrates the simple model of how a client buffer is mapped by system software to the periodic schedule (that is the periodic frame list and a set of iTDs). On the right is the client description of its request. The description includes a buffer base address plus additional annotations to identify which portions of the buffer should be used with each bus transaction. In the middle is the iTD data structures used by the system software to service the client request. Each iTD can be initialized to service up to 24 transactions, organized into eight groups of up to three transactions each. Each group maps to one micro-frame's worth of transactions. The EHCI controller does not provide per-transaction results within a micro-frame. It treats the per-micro-frame transactions as a single logical transfer. On the left is the host controller's frame list. System software establishes references from the appropriate locations in the frame list to each of the appropriate iTDs. If the buffer is large, then system software can use a small set of iTDs to service the entire buffer. System software can activate the transaction description records (contained in each iTD) in any pattern required for the particular data stream.

**Figure 11-71. Example Association of iTDs to Client Request Buffer**

As noted above, the client request includes a pointer to the base of the buffer and offsets into the buffer to annotate which buffer sections are to be used on each bus transaction that occurs on this endpoint. System software must initialize each transaction description in an iTD to ensure it uses the correct portion of the client buffer. For example, for each transaction description, the PG field is set to index the correct physical buffer page pointer and the Transaction Offset field is set relative to the correct buffer pointer page (for example, the same one referenced by the PG field). When the host controller executes a transaction it selects a transaction description record based on FRINDEX[2:0]. It then uses the current Page Buffer Pointer (as selected by the PG field) and concatenates to the transaction offset field. The result is a starting buffer address for the transaction. As the host controller moves data for the transaction, it must watch for a page wrap condition and properly advance to the next available Page Buffer Pointer. System software must not use the Page 6 buffer pointer in a transaction description where the length of the transfer wraps a page boundary. Doing so yields undefined behavior. The host controller hardware is not required to 'alias' the page selector to Page zero. USB 2.0 isochronous

endpoints can specify a period greater than one. Software can achieve the appropriate scheduling by linking iTDs into the appropriate frames (relative to the frame list) and by setting appropriate transaction description elements active bits to one.

#### 11.4.4.3.7.2.1 *Periodic scheduling threshold*

The Isochronous Scheduling Threshold field in the USB\_HCCPARAMS capability register is an indicator to system software as to how the host controller pre-fetches and effectively caches schedule data structures.

It is used by system software when adding isochronous work items to the periodic schedule. The value of this field indicates to system software the minimum distance it can update isochronous data (relative to the current location of the host controller execution in the periodic list) and still have the host controller process them.

The iTD and siTD data structures each describe 8 micro-frames worth of transactions. The host controller is allowed to cache one (or more) of these data structures in order to reduce memory traffic. Three basic caching models that account for the fact the isochronous data structures span 8 micro-frames. The three caching models are: no caching, micro-frame caching and frame caching.

When software is adding new isochronous transactions to the schedule, it always performs a read of the USB\_FRINDEX register to determine the current frame and micro-frame the host controller is currently executing. Of course, there is no information about where in the micro-frame the host controller is, so a constant uncertainty-factor of one micro-frame has to be assumed. Combining the knowledge of where the host controller is executing with the knowledge of the caching model allows the definition of simple algorithms for how closely software can reliably work to the executing host controller.

No caching is indicated with a value of zero in the Isochronous Scheduling Threshold field. The host controller may pre-fetch data structures during a periodic schedule traversal (per micro-frame) but always dumps any accumulated schedule state at the end of the micro-frame. At the appropriate time relative to the beginning of every micro-frame, the host controller always begins schedule traversal from the frame list. Software can use the value of the USB\_FRINDEX register (plus the constant 1 uncertainty-factor) to determine the approximate position of the executing host controller. When no caching is selected, software can add an isochronous transaction as near as 2 micro-frames in front of the current executing position of the host controller.

Frame caching is indicated with a non-zero value in bit [7] of the Isochronous Scheduling Threshold field. In the frame-caching model, system software assumes that the host controller caches one (or more) isochronous data structures for an entire frame (8 micro-frames). Software uses the value of the USB\_FRINDEX register (plus the constant 1

uncertainty) to determine the current micro-frame/frame (assume modulo 8 arithmetic in adding the constant 1 to the micro-frame number). For any current frame N, if the current micro-frame is 0 to 6, then software can safely add isochronous transactions to Frame N + 1. If the current micro-frame is 7, then software can add isochronous transactions to Frame N + 2.

Micro-frame caching is indicated with a non-zero value in the least-significant 3 bits of the Isochronous Scheduling Threshold field. System software assumes the host controller caches one or more periodic data structures for the number of micro-frames indicated in the Isochronous Scheduling Threshold field. For example, if the count value were 2, then the host controller keeps a window of 2 micro-frames worth of state (current micro-frame, plus the next) on-chip. On each micro-frame boundary, the host controller releases the current micro-frame state and begins accumulating the next micro-frame state.

#### **11.4.4.3.8 Asynchronous Schedule**

The Asynchronous schedule traversal is enabled or disabled through the Asynchronous Schedule Enable bit in the USB\_USBCMD register.

If the Asynchronous Schedule Enable bit is set to zero, then the host controller simply does not try to access the asynchronous schedule through the USB\_ASYNCLISTADDR register. Likewise, when the Asynchronous Schedule Enable bit is one, then the host controller does use the USB\_ASYNCLISTADDR register to traverse the asynchronous schedule. Modifications to the Asynchronous Schedule Enable bit are not necessarily immediate. Rather the new value of the bit is taken into consideration the next time the host controller needs to use the value of the USB\_ASYNCLISTADDR register to get the next queue head.

The Asynchronous Schedule Status bit in the USB\_USBSTS register indicates status of the asynchronous schedule. System software enables (or disables) the asynchronous schedule by writing one (or zero) to the Asynchronous Schedule Enable bit in the USB\_USBCMD register. Software then can poll the Asynchronous Schedule Status bit to determine when the asynchronous schedule has made the desired transition. Software must not modify the Asynchronous Schedule Enable bit unless the value of the Asynchronous Schedule Enable bit equals that of the Asynchronous Schedule Status bit.

The asynchronous schedule is used to manage all Control and Bulk transfers. Control and Bulk transfers are managed using queue head data structures. The asynchronous schedule is based at the USB\_ASYNCLISTADDR register. The default value of the USB\_ASYNCLISTADDR register after reset is undefined and the schedule is disabled when the Asynchronous Schedule Enable bit is zero.

Software may only write this register with defined results when the schedule is disabled. For example, Asynchronous Schedule Enable bit in the USB\_USBCMD and the Asynchronous Schedule Status bit in the USB\_USBSTS register are zero. System software enables execution from the asynchronous schedule by writing a valid memory address (of a queue head) into this register. Then software enables the asynchronous schedule by setting the Asynchronous Schedule Enable bit to one. The asynchronous schedule is actually enabled when the Asynchronous Schedule Status bit is one.

When the host controller begins servicing the asynchronous schedule, it begins by using the value of the USB\_ASYNCLISTADDR register. It reads the first referenced data structure and begins executing transactions and traversing the linked list as appropriate. When the host controller completes processing the asynchronous schedule, it retains the value of the last accessed queue head's horizontal pointer in the USB\_ASYNCLISTADDR register. Next time the asynchronous schedule is accessed, this is the first data structure that is serviced. This provides round-robin fairness for processing the asynchronous schedule.

A host controller completes processing the asynchronous schedule when one of the following events occur:

- The end of a micro-frame occurs.
- The host controller detects an empty list condition (see [Empty Asynchronous Schedule Detection](#) )
- The schedule has been disabled through the Asynchronous Schedule Enable bit in the USB\_USBCMD register.

The queue heads in the asynchronous list are linked into a simple circular list as shown in [Figure 11-66](#). Queue head data structures are the only valid data structures that may be linked into the asynchronous schedule. An isochronous transfer descriptor (iT or siTD) in the asynchronous schedule yields undefined results.

The maximum packet size field in a queue head is sized to accommodate the use of this data structure for all non-isochronous transfer types. The USB Specification, Revision 2.0 specifies the maximum packet sizes for all transfer types and transfer speeds. System software should always parameterize the queue head data structures according to the core specification requirements.

#### 11.4.4.3.8.1 Adding Queue Heads to Asynchronous Schedule

This is a software requirement section.

There are two independent events for adding queue heads to the asynchronous schedule. The first is the initial activation of the asynchronous list. The second is inserting a new queue head into an activated asynchronous list.

Activation of the list is simple. System software writes the physical memory address of a queue head into the USB\_ASYNCLISTADDR register, then enables the list by setting the Asynchronous Schedule Enable bit in the USB\_USBCMD register to one.

When inserting a queue head into an active list, software must ensure that the schedule is always coherent from the host controllers' point of view. This means that the system software must ensure that all queue head pointer fields are valid. For example, qTD pointers have T-Bits set to one or reference valid qTDs and the Horizontal Pointer references a valid queue head data structure. The following algorithm represents the functional requirements:

```
InsertQueueHead (pQHeadCurrent, pQueueHeadNew)
--
-- Requirement: all inputs must be properly initialized.
--
-- pQHeadCurrent is a pointer to a queue head that is
-- already in the active list
-- pQHeadNew is a pointer to the queue head to be added
--
-- This algorithm links a new queue head into a existing
-- list
--
pQueueHeadNew.HorizontalPointer = pQueueHeadCurrent.HorizontalPointer
pQueueHeadCurrent.HorizontalPointer = physicalAddressOf (pQueueHeadNew)
End InsertQueueHead
```

### 11.4.4.3.8.2 Removing Queue Heads from Asynchronous Schedule

This is a software requirement section.

There are two independent events for removing queue heads from the asynchronous schedule. The first is shutting down (deactivating) the asynchronous list. The second is extracting a single queue head from an activated list.

Software deactivates the asynchronous schedule by setting the Asynchronous Schedule Enable bit in the USB\_USBCMD register to zero. Software can determine when the list is idle when the Asynchronous Schedule Status bit in the USB\_USBSTS register is zero. The normal mode of operation is that software removes queue heads from the asynchronous schedule without shutting it down. Software must not remove an active queue head from the schedule. Software should first deactivate all active qTDs, wait for the queue head to go inactive, then remove the queue head from the asynchronous list. Software removes a queue head from the asynchronous list through the following algorithm. As illustrated, the unlinking is quite easy. Software merely must ensure all of the link pointers reachable by the host controller are kept consistent.

```
UnlinkQueueHead (pQHeadPrevious, pQueueHeadToUnlink, pQHeadNext)
--
-- Requirement: all inputs must be properly initialized.
--
-- pQHeadPrevious is a pointer to a queue head that
-- references the queue head to remove
```

```

-- pQHeadToUnlink is a pointer to the queue head to be
-- removed
-- pQheadNext is a pointer to a queue head still in the
-- schedule. Software provides this pointer with the
-- following strict rules:
--     if the host software is one queue head, then
--     pQheadNext must be the same as
--     QueueheadToUnlink.HorizontalPointer. If the host
--     software is unlinking a consecutive series of
--     queue heads, QHeadNext must be set by software to
--     the queue head remaining in the schedule.
--
-- This algorithm unlinks a queue head from a circular list
--
pQueueHeadPrevious.HorizontalPointer = pQueueHeadToUnlink.HorizontalPointer
pQueueHeadToUnlink.HorizontalPointer = pQHeadNext

```

End UnlinkQueueHead

If software removes the queue head with the H-bit set to one, it must select another queue head still linked into the schedule and set its H-bit to one. This should be completed before removing the queue head. The requirement is that software keep one queue head in the asynchronous schedule, with its H-bit set to one. At the point software has removed one or more queue heads from the asynchronous schedule, it is unknown whether the host controller has a cached pointer to them. Similarly, it is unknown how long the host controller might retain the cached information, as it is implementation dependent and may be affected by the actual dynamics of the schedule load. Therefore, once software has removed a queue head from the asynchronous list, it must retain the coherency of the queue head (link pointers, and so on). It cannot disturb the removed queue heads until it knows that the host controller does not have a local copy of a pointer to any of the removed data structures.

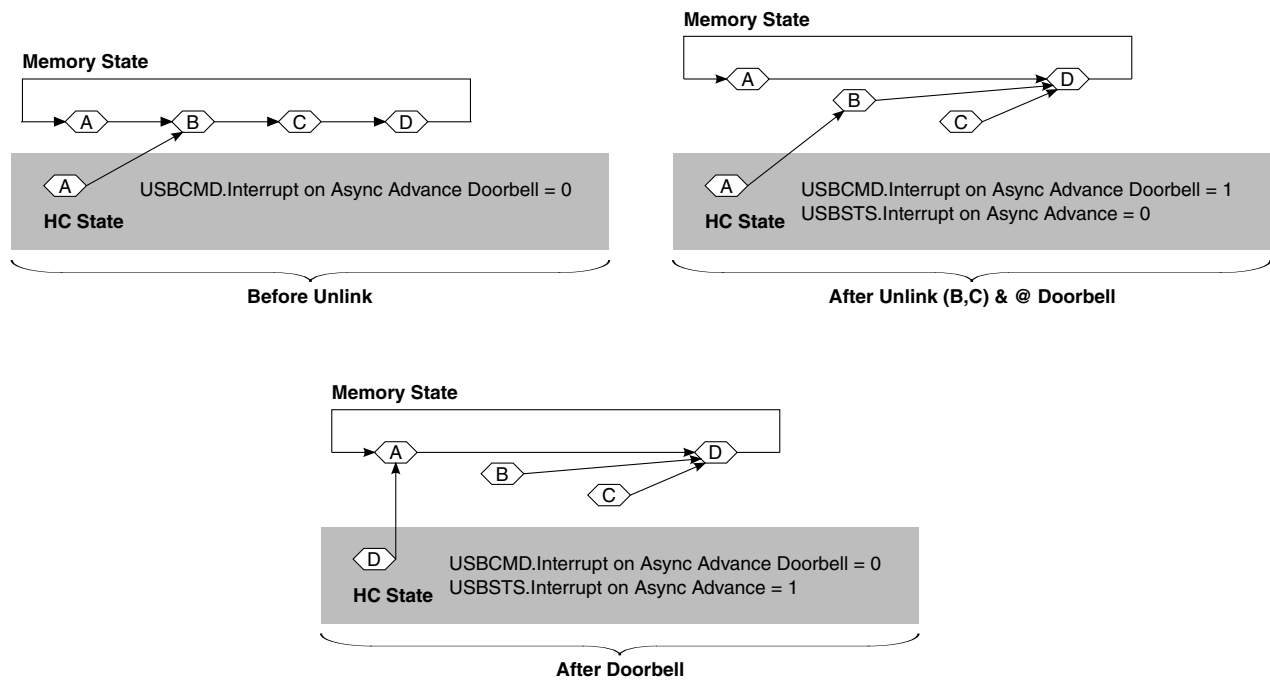

The method software uses to determine when it is safe to modify a removed queue head is to handshake with the host controller. The handshake mechanism allows software to remove items from the asynchronous schedule, then execute a simple, lightweight handshake that is used by software as a key that it can free (or reuse) the memory associated the data structures it has removed from the asynchronous schedule.

The handshake is implemented with three bits in the host controller. The first bit is a command bit (Interrupt on Async Advance Doorbell bit in the USB\_USBCMD register) that allows software to inform the host controller that something has been removed from its asynchronous schedule. The second bit is a status bit (Interrupt on Async Advance bit in the USB\_USBSTS register) that the host controller sets after it has released all on-chip state that may potentially reference one of the data structures just removed. When the host controller sets this status bit to one, it also sets the command bit to zero. The third bit is an interrupt enable (Interrupt on Async Advance bit in the USB\_USBINTR register) that is matched with the status bit. If the status bit is one and the interrupt enable bit is one, then the host controller asserts a hardware interrupt.

The figure below illustrates a general example. In this example, consecutive queue heads (B and C) are unlinked from the schedule using the algorithm above. Before the unlink operation, the host controller has a copy of queue head A.

The unlink algorithm requires that as software unlinks each queue head, the unlinked queue head is loaded with the address of a queue head that remains in the asynchronous schedule.

When the host controller observes that doorbell bit being set to one, it makes a note of the local reachable schedule information. In this example, the local reachable schedule information includes both queue heads (A and B). It is sufficient that the host controller can set the status bit (and clear the doorbell bit) as soon as it has traversed beyond current reachable schedule information (that is traversed beyond queue head (B) in this example). The following figure illustrates the generic queue head unlink scenario.

**Figure 11-72. Generic Queue Head Unlink Scenario**

Alternatively, a host controller implementation is allowed to traverse the entire asynchronous schedule list (for example, observed the head of the queue (twice)) before setting the Advance on Async status bit to one.

Software may re-use the memory associated with the removed queue heads after it observes the Interrupt on Async Advance status bit is set to one, following assertion of the doorbell. Software should acknowledge the Interrupt on Async Advance status as indicated in the `USB_USBSTS` register, before using the doorbell handshake again.

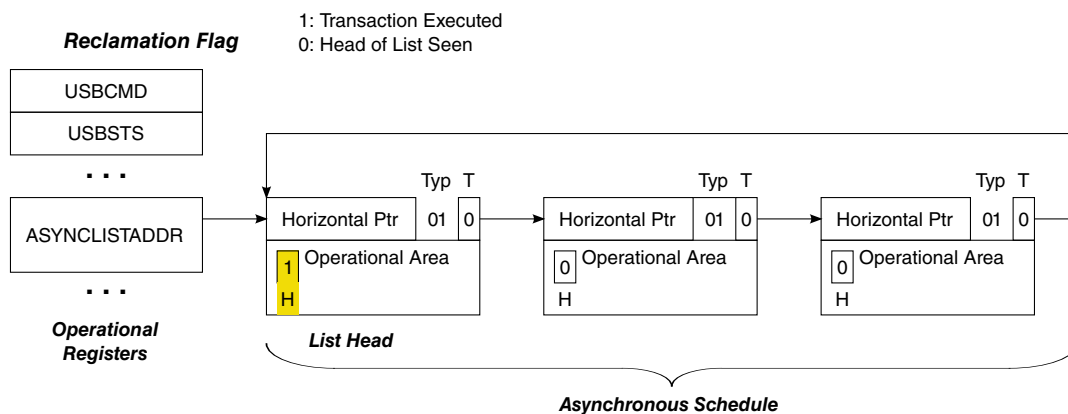

### 11.4.4.3.8.3 Empty Asynchronous Schedule Detection

The Enhanced Host Controller Interface uses two bits to detect when the asynchronous schedule is empty.

The queue head data structure (see [Table 11-81](#)) defines an *H-bit* in the queue head, which allows software to mark a queue head as being the *head* of the reclaim list. The Enhanced Host Controller Interface also keeps a 1-bit flag in the USB\_USBSTS register (*Reclamation*) that is set to zero when the Enhanced Interface Host Controller observes a queue head with the H-bit set to one. The reclamation flag in the status register is set to one when any USB transaction from the asynchronous schedule is executed (or whenever the asynchronous schedule starts, see [Asynchronous schedule traversal: Start Event](#)).

If the Enhanced Host Controller Interface ever encounters an *H-bit* of one and a *Reclamation* bit of zero, the EHCI controller simply stops traversal of the asynchronous schedule.

An example illustrating the H-bit in a schedule is shown in the following figure.

**Figure 11-73. Asynchronous Schedule List w/Annotation to Mark Head of List**

Software must ensure there is at most one queue head with the *H-bit* set to one, and that it is always coherent with respect to the schedule.

### 11.4.4.3.8.4 Restarting Asynchronous Schedule Before EOF

There are many situations where the host controller will detect an empty list *long* before the end of the micro-frame.

It is important to remember that under many circumstances the schedule traversal has stopped due to Nak/Nyet responses from all endpoints.

An example of particular interest is when a start-split for a bulk endpoint occurs early in the micro-frame. Given the EHCI simple traversal rules, the complete-split for that transaction may Nak/Nyet out very quickly. If it is the only item in the schedule, then the host controller ceases traversal of the Asynchronous schedule very early in the micro-frame. In order to provide reasonable service to this endpoint, the host controller should issue the complete-split before the end of the current micro-frame, instead of waiting until the next micro-frame. When the reason for host controller idling asynchronous schedule traversal is because of empty list detection, it is mandatory the host controller implement a 'waking' method to resume traversal of the asynchronous schedule. An example method is described below.

#### 11.4.4.3.8.4.1 Example Method for Restarting Asynchronous Schedule Traversal

The reason for idling the host controller when the list is empty is to keep the host controller from unnecessarily occupying too much memory bandwidth. The question is: *how long should the host controller stay idle before restarting?*

The answer in this example is based on deriving a manifest constant, which is the amount of time the host controller will stay idle before restarting traversal. In this example, the manifest constant is called *AsyncSchedSleepTime*, and has a value of 10  $\mu$ sec. The value is derived based on the analysis in [Example Derivation for AsyncSchedSleepTime](#). The traversal algorithm is simple:

- Traverse the Asynchronous schedule until the either an End-Of-micro-Frame event occurs, or an empty list is detected. If the event is an End-of-micro-Frame, go attempt to traverse the Periodic schedule. If the event is an empty list, then set a sleep timer and go to a *schedule sleep* state.
- When the sleep timer expires, set working context to the Asynchronous Schedule start condition and go to *schedule active* state. The start context allows the HC to reload *Nakcnt* fields, and so on. So the HC has a chance to run for more than one iteration through the schedule.

This process simply repeats itself each micro-frame. The figure below illustrates a sample state machine to manage the active and sleep states of the Asynchronous Schedule traversal policy. There are three states: Actively traversing the Asynchronous schedule, Sleeping, and Not Active. The last two are similar in terms of interaction with the Asynchronous schedule, but the Not Active state means that the host controller is busy with the Periodic schedule or the Asynchronous schedule is not enabled. The Sleeping state is specifically a special state where the host controller is just waiting for a period of time before resuming execution of the Asynchronous schedule.

**Figure 11-74. Example State Machine for Managing Asynchronous Schedule Traversal**

The actions referred to in the figure above are defined in the following table.

**Table 11-96. Asynchronous Schedule SM Transition Actions**

Action	Action Description Label
A	On detection of the empty list, the host controller sets the <i>AsynchronousTraversalSleepTimer</i> to <i>AsynSchedSleepTime</i> .
B	When the <i>AsynchronousTraversalSleepTimer</i> expires, the host controller sets the <i>Reclamation</i> bit in the USBSTS register to one and moves the Nak Counter reload state machine to WaitForListHead (see <a href="#">Nak Count Reload Control</a> ).
C	The host controller cancels the sleep timer ( <i>AsynchronousTraversalSleepTimer</i> ).

#### 11.4.4.3.8.4.2 *Asyn Sched Not Active*

This is the initial state of the traversal state machine after a host controller reset. The traversal state machine does not leave this state when the *Asynchronous Schedule Enable* bit in the USB\_USBCMD register is zero.

This state is entered from Asyn Sched Active or Asyn Sched Sleeping states when the end-of-micro-frame event is detected.

#### 11.4.4.3.8.4.3 *Asyn Sched Active*

This state is entered from the Asyn Sched Not Active state when the periodic schedule is not active. It is also entered from the Asyn Sched Sleeping states when the *AsynSchedSleepTimer* expires. On every transition into this state, the host controller sets the *Reclamation* bit in the USB\_USBSTS register to one.

While in this state, the host controller continually traverses the asynchronous schedule until either the end of micro-frame or an empty list condition is detected.

11.4.4.3.8.4.4 Async Sched Sleeping

The state is entered from the Async Sched Active state when a schedule empty condition is detected. On entry to this state, the host controller sets the *AsynchronousTraversalSleepTimer* to *AsyncSchedSleepTime*.

11.4.4.3.8.4.5 Example Derivation for AsyncSchedSleepTime

The derivation is based on analysis of what work the host controller could be doing next.

It assumes the host controller does not keep any state about what work is possibly pending in the asynchronous schedule. The schedule could contain any mix of the possible combinations of high- full- or low-speed control and bulk requests.

The table below summarizes some of the typical 'next transactions' that could be in the schedule, and the amount of time (for example *footprint*, or *wall clock*) the transaction takes to complete.

**Table 11-97. Typical Low-/Full-speed Transaction Times**

Transaction Attributes		Footprint (time)	Description
Speed	HS	11.9 ms	Maximum foot print for a worst-case, full-sized bulk data transaction.
Size	512	9.45 ms	Maximum footprint for an approximate best-case, full-sized bulk data transaction.
Type	Bulk		
Speed	FS	~50 ms	Approximate typical for full-sized bulk data. An 8-byte low-speed is about 2x, or between 90 and 100 ms.
Size	64		
Type	Bulk		
Speed	FS	~12 ms	Approximate typical for 8-byte bulk/control (that is setup)
Size	8		
Type	Cntrl		

A *AsyncSchedSleepTime* value of 10  $\mu$ s provides a reasonable relaxation of the system memory load and still provides a good level of service for the various transfer types and payload sizes. For example, say we detect an empty list after issuing a start-split for a 64-byte full-speed bulk request. Assuming this is the only thing in the list, the host controller gets the results of the full-speed transaction from the hub during the fifth complete-split request. If the full-speed transaction was an IN and it nak'd, the 10  $\mu$ s sleep period would allow the host controller to get the NAK results on the first complete-split.

#### 11.4.4.3.8.5 Asynchronous schedule traversal: *Start Event*

Once the HC has *idled* itself through the empty schedule detection (Section 0), it will naturally *activate* and begin processing from the Periodic Schedule at the beginning of each micro-frame.

In addition, it may have idled itself early in a micro-frame. When this occurs (idles early in the micro-frame) the HC must occasionally *re-activate* during the micro-frame and traverse the asynchronous schedule to determine whether any progress can be made. The requirements and method for this restart are described in [Restarting Asynchronous Schedule Before EOF](#) . Asynchronous schedule *Start Events* are defined to be:

- Whenever the host controller transitions from the periodic schedule to the asynchronous schedule. If the periodic schedule is disabled and the asynchronous schedule is enabled, then the beginning of the micro-frame is equivalent to the transition from the periodic schedule, or
- The asynchronous schedule traversal restarts from a sleeping state (see [Restarting Asynchronous Schedule Before EOF](#) ).

#### 11.4.4.3.8.6 Reclamation Status Bit (USBSTS Register)

The operation of the empty asynchronous schedule detection feature (see [Empty Asynchronous Schedule Detection](#) ) depends on the proper management of the *Reclamation* bit in the USB\_USBSTS register.

The host controller tests for an empty schedule just after it fetches a new queue head while traversing the asynchronous schedule (see [Fetch Queue Head](#) ).

It is required that the host controller sets the *Reclamation* bit to one whenever an asynchronous schedule traversal *Start Event*, as documented in [Asynchronous schedule traversal: Start Event](#), occurs. The *Reclamation* bit is also set to one whenever the host controller executes a transaction while traversing the asynchronous schedule (see [Execute Transaction](#) ). The host controller sets the *Reclamation* bit to zero whenever it finds a queue head with its *H-bit* set to one. Software should only set a queue head's *H-bit* if the queue head is in the asynchronous schedule. If software sets the *H-bit* in an interrupt queue head to one, the resulting behavior is undefined. The host controller may set the *Reclamation* bit to zero when executing from the periodic schedule.

#### 11.4.4.3.9 Operational Model for Nak Counter

This section describes the operational model for the *NakCnt* field defined in a queue head.

See [Queue Head Initialization](#) for more information. Software should not use this feature for interrupt queue heads. This rule is not required to be enforced by the host controller.

USB protocol has built-in flow control through the Nak response by a device. There are several scenarios, beyond the Ping feature, where an endpoint may naturally Nak or Nyet the majority of the time. An example is the host controller management of the split transaction protocol for control and bulk endpoints. All bulk endpoints (High- or Full-speed) are serviced through the same asynchronous schedule. The time between the *Start-split* transaction and the first *Complete-split* transaction could be very short (that is like when the endpoint is the only one in the asynchronous schedule). The hub NYETs (effectively Naks) the *Complete-split* transaction until the classic transaction is complete. This could result in the host controller thrashing memory, repeatedly fetching the queue head and executing the transaction to the Hub, which does not complete until after the transaction on the classic bus completes.

The two component fields in a queue head to support the throttling feature: a counter field (*NakCnt*), and a counter reload field (*RL*). *NakCnt* is used by the host controller as one of the criteria to determine whether or not to execute a transaction to the endpoint. The two operational modes associated with this counter:

- Not Used- This mode is set when the *RL* field is zero. The host controller ignores the *NakCnt* field for any execution of transactions through a queue head with an *RL* field of zero. Software must use this selection for interrupt endpoints.
- Nak Throttle Mode- This mode is selected when the *RL* field is non-zero. In this mode, the value in the *NakCnt* field represents the maximum number of Nak or Nyet responses the host controller tolerates on each endpoint. In this mode, the HC decrements the *NakCnt* field based on the token/handshake criteria listed in the table below. The host controller must reload *NakCnt* when the endpoint successfully moves data (for example, policy to reward device for moving data).

The following table describes the *NakCnt* field adjustment rules.

**Table 11-98. NakCnt Field Adjustment Rules**

Token	Handshake	
	Handshake NAK	NYET
IN/PING	decrement <i>NakCnt</i>	N/A (protocol error)
OUT	decrement <i>NakCnt</i>	No Action <sup>1</sup> Start
Split	decrement <i>NakCnt</i>	N/A (protocol error)
Complete Split	No Action	Decrement <i>NakCnt</i>

1. Recommended behavior on this response is to reload *NakCnt*

In summary, system software enables the counter by setting the reload field (*RL*) to a non-zero value. The host controller may execute a transaction if *NakCnt* is non-zero. The host controller does not execute a transaction if *NakCnt* is zero. The reload mechanism is described in detail in [Nak Count Reload Control](#).

### NOTE

When all queue heads in the Asynchronous Schedule either exhausts all transfers or all *NakCnt*'s go to zero, then the host controller detects an empty Asynchronous Schedule and idle schedule traversal (see [Empty Asynchronous Schedule Detection](#)).

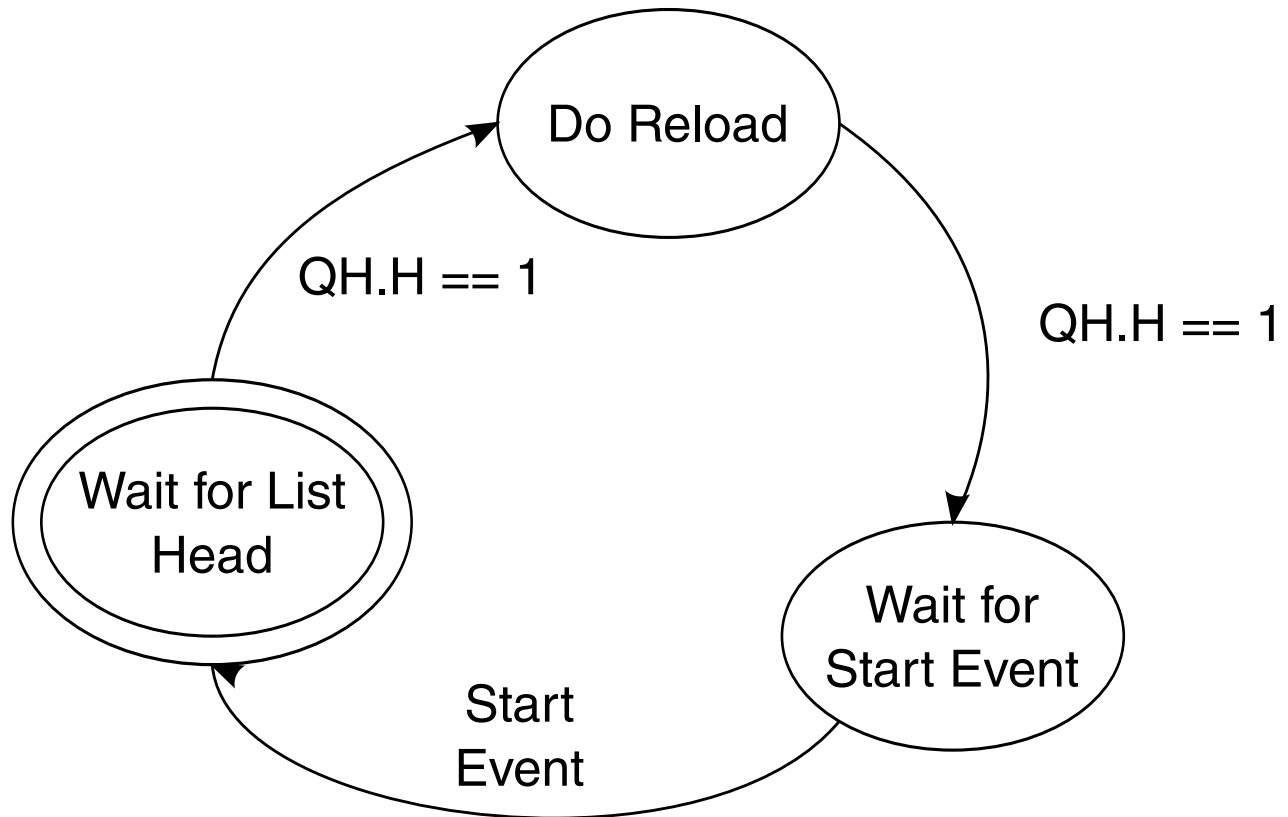

Any time the host controller begins a new traversal of the Asynchronous Schedule, a *Start Event* is assumed, see [Asynchronous schedule traversal: Start Event](#). Every time a Start-Event occurs, the Nak Count reload procedure is enabled.

#### 11.4.4.3.9.1 Nak Count Reload Control

When the host controller reaches the *Execute Transaction* state for a queue head (meaning that it has an active operational state), it checks to determine whether the *NakCnt* field should be reloaded from *RL* (see [Execute Transaction](#)). If the answer is yes, then *RL* is copied into *NakCnt*. After the reload or if the reload is not active, the host controller evaluates whether to execute the transaction.

The host controller must reload nak counters (*NakCnt* see [Table 11-81](#)) in queue heads during the first pass through the reclamation list after an asynchronous schedule Start Event (see [Asynchronous schedule traversal: Start Event](#) for the definition of the Start Event). The Asynchronous Schedule should have at most one queue head marked as the head (see [Figure 11-73](#)).

The following figure illustrates an example state machine that satisfies the operational requirements of the host controller detecting the first pass through the Asynchronous Schedule. This state machine is maintained internal to the host controller and is only used to gate reloading of the nak counter during the queue head traversal state: Execute Transaction (see the figure below). The host controller does not perform the nak counter reload operation if the *RL* field (see [Table 11-81](#)) is set to zero.

**Figure 11-75. Example HC State Machine for Controlling Nak Counter Reloads**

**11.4.4.3.9.1.1 Wait for List Head**

This is the initial state.

The state machine enters this state from Wait for Start Event when a start event as defined in [Asynchronous schedule traversal: Start Event](#) occurs.

The purpose of this state is to wait for the first observation of the head of the Asynchronous Schedule.

This occurs when the host controller fetches a queue head whose *H-bit* is set to one.

**11.4.4.3.9.1.2 Do Reload**

This state is entered from the Wait for List Head state when the host controller fetches a queue head with the *H-bit* set to one. While in this state, the host controller performs nak counter reloads for every queue head visited that has a non-zero nak reload value (*RL*) field.

#### 11.4.4.3.9.1.3 Wait for Start Event

This state is entered from the *Do Reload* state when a queue head with the *H-bit* set to one is fetched. While in this state, the host controller does not perform nak counter reloads.

### 11.4.4.3.10 Managing Control/Bulk/Interrupt Transfers through Queue Heads

This section presents an overview of how the host controller interacts with queuing data structures.

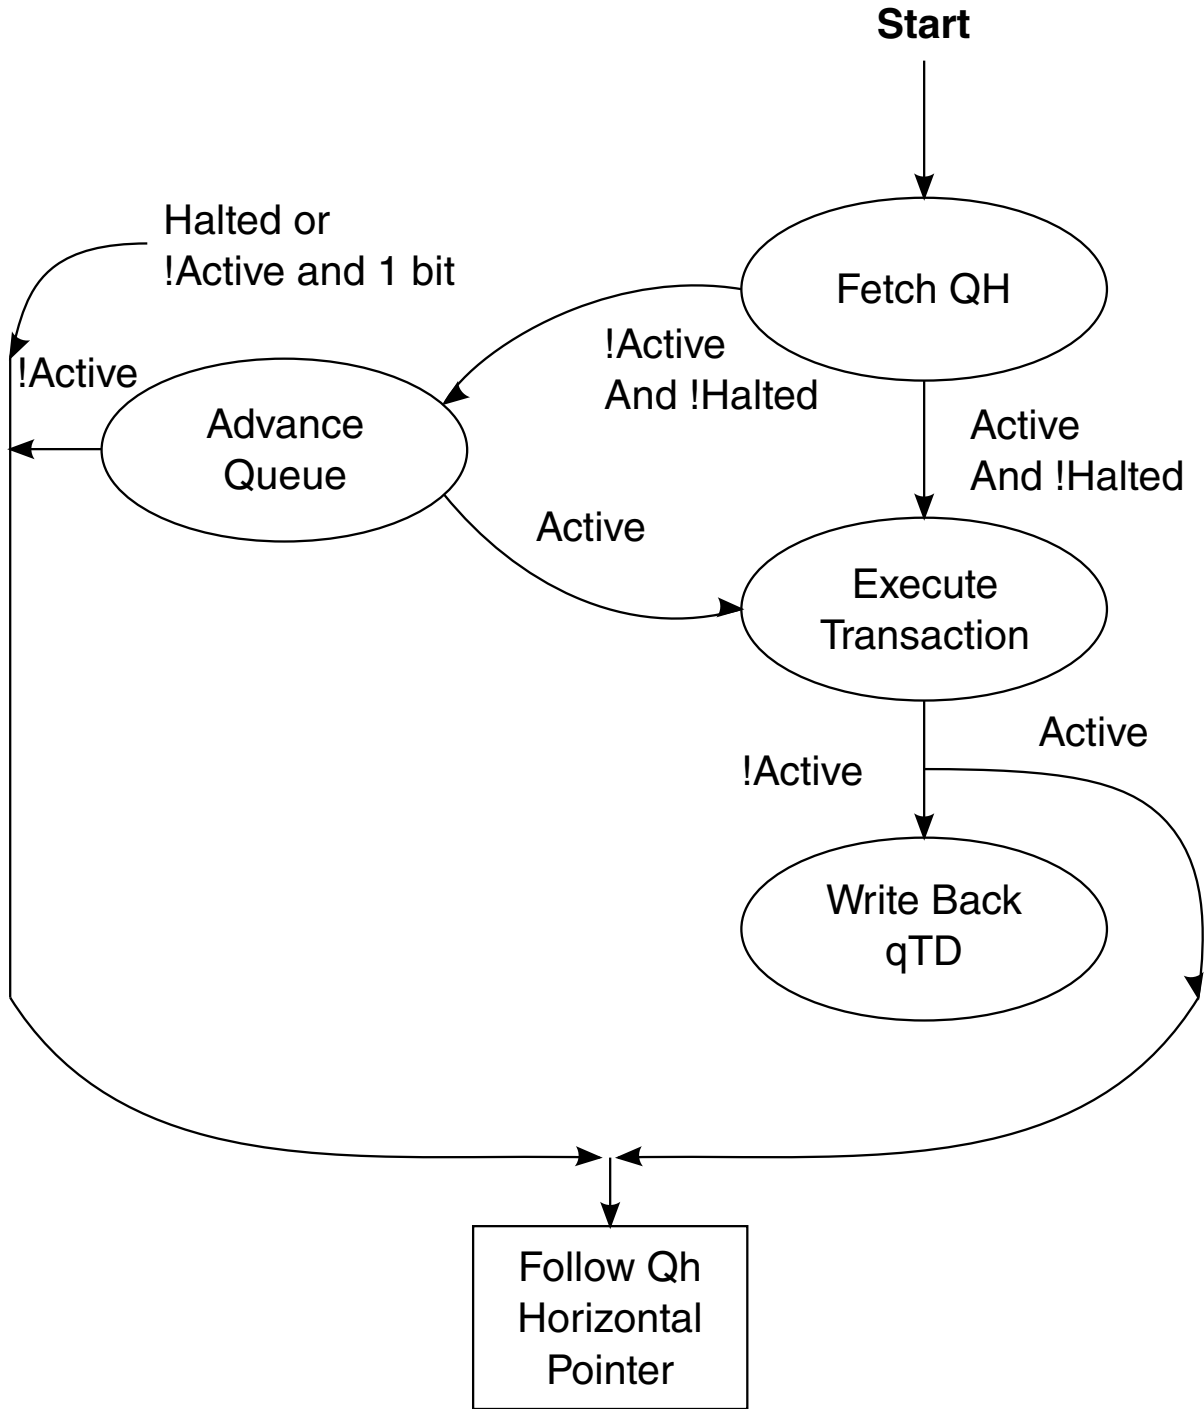

Queue heads use the Queue Element Transfer Descriptor (qTD) structure. One queue head is used to manage the data stream for one endpoint. The queue head structure contains static endpoint characteristics and capabilities. It also contains a working area from where individual bus transactions for an endpoint are executed (see Overlay area defined in [Table 11-81](#)). Each qTD represents one or more bus transactions, which is defined in the context of this specification as a *transfer*.

The general processing model for the host controller's use of a queue head is simple:

- read a queue head,
- execute a transaction from the overlay area,
- write back the results of the transaction to the overlay area,
- move to the next queue head.

If the host controller encounters errors during a transaction, the host controller sets one (or more) of the error reporting bits in the queue head's *Status* field. The *Status* field accumulates all errors encountered during the execution of a qTD (for example, the error bits in the queue head *Status* field are 'sticky' until the transfer (qTD) has completed). This state is always written back to the source qTD when the transfer is complete. On transfer (for example, buffer or halt conditions) boundaries, the host controller must auto-advance (without software intervention) to the next qTD. Additionally, the hardware must be able to halt the queue so no additional bus transactions occurs for the endpoint and the host controller does not advance the queue.

An example host controller operational state machine of a queue head traversal is illustrated in the following figure. This state machine is a model for how a host controller should traverse a queue head. The host controller must be able to advance the queue from the *Fetch QH* state in order to avoid all hardware/software race conditions. This simple mechanism allows software to simply link qTDs to the queue head and *activate* them, then the host controller always *find* them if/when they are reachable. The figure below illustrates the Host Controller Queue Head Traversal State Machine.

**Figure 11-76. Host Controller Queue Head Traversal State Machine**

This traversal state machine applies to all queue heads, regardless of transfer type or whether split transactions are required. The following sections describe each state. Each state description describes the entry criteria. The Execute Transaction state (see [Execute](#)

[Transaction](#) ) describes the basic requirements for all endpoints. [Split Transactions for Asynchronous Transfers](#) and [Split Transaction Interrupt](#) describe details of the required extensions to the Execute Transaction state for endpoints requiring split transactions.

### NOTE

Prior to software placing a queue head into either the periodic or asynchronous list, software must ensure the queue head is properly initialized. Minimally, the queue head should be initialized to the following (see Section Queue Head for layout of a queue head):

Valid static endpoint state.

- For the very first use of a queue head, software may zero-out the queue head transfer overlay, then set the *Next qTD Pointer* field value to reference a valid qTD.

#### 11.4.4.3.10.1 Fetch Queue Head

A queue head can be referenced from the physical address stored in the ASYNCLISTADDR Register (see [Next Asynch. Address \(USB\\_ASYNCLISTADDR\)](#))/[Endpoint List Address \(USB\\_ENDPTLISTADDR\)](#) Additionally, it may be referenced from the *Next LinkPointer* field of an iTD, siTD, FSTN or another Queue Head. If the referencing link pointer has the *Typ* field set to indicate a queue head, it is assumed to reference a queue head structure as defined in [Table 11-81](#).

While in this state, the host controller performs operations to implement empty schedule detection (see [Empty Asynchronous Schedule Detection](#) ) and Nak Counter reloads (see [Operational Model for Nak Counter](#)). After the queue head has been fetched, the host controller conducts the following queries for empty schedule detection:

- If queue head is not an interrupt queue head (that is *S-mask* is zero), and
- The *H-bit* is one, and
- The *Reclamation* bit in the USBSTS register is zero.

When these criteria are met, the host controller stops traversing the asynchronous list (as described in [Empty Asynchronous Schedule Detection](#) ). When the criteria are not met, the host controller continues schedule traversal. If the queue head is not an interrupt and the *H-bit* is one and the *Reclamation* bit is one, then the host controller sets the *Reclamation* bit in the USBSTS register to zero before completing this state. The operations for reloading of the Nak Counter are described in detail in [Operational Model for Nak Counter](#).

This state is complete when the queue head has been read on-chip.

### 11.4.4.3.10.2 Advance Queue

To advance the queue, the host controller must find the next qTD, adjust pointers, perform the overlay and write back the results to the queue head.

This state is entered from the FetchQHD state if the overlay *Active* and *Halt* bits are set to zero. On entry to this state, the host controller determines which next pointer to use to fetch a qTD, fetches a qTD and determines whether or not to perform an overlay.

#### NOTE

If the *I-bit* is one and the *Active* bit is zero, the host controller immediately skips processing of this queue head, exits this state and uses the horizontal pointer to the next schedule data structure. If the field *Bytes to Transfer* is not zero and the *T-bit* in the *Alternate Next qTD Pointer* is set to zero, then the host controller uses the *Alternate Next qTD Pointer*. Otherwise, the host controller uses the *NextqTD Pointer*. If *NextqTD Pointer's T-bit* is set to one, then the host controller exits this state and uses the horizontal pointer to the next schedule data structure.

Using the selected pointer the host controller fetches the referenced qTD. If the fetched qTD has its *Active* bit set to one, the host controller moves the pointer value used to reach the qTD (*Next* or *Alternate Next*) to the *Current qTD Pointer* field, then performs the overlay. If the fetched qTD has its *Active* bit set to zero, the host controller aborts the queue advance and follows the queue head's horizontal pointer to the next schedule data structure.

The host controller performs the overlay based on the following rules:

- The value of the data toggle (*dt*) field in the overlay area depends on the value of the *data toggle control (dtc)* bit (see [Table 11-83](#)).
- If the *EPS* field indicates the endpoint is a high-speed endpoint, the *Ping* state field is preserved by the host controller. The value of this field is not changed as a result of the overlay.
- *C-prog-mask* field is set to zero (field from incoming qTD is ignored, as is the current contents of the overlay area).
- *Frame Tag* field is set to zero (field from incoming qTD is ignored, as is the current contents of the overlay area).
- *NakCnt* field in the overlay area is loaded from the *RL* field in the queue head's Static Endpoint State.
- All other areas of the overlay are set by the incoming qTD.

The host controller exits this state when it has committed the write to the queue head.

### 11.4.4.3.10.3 Execute Transaction

The host controller enters this state from the Fetch Queue Head state only if the *Active* bit in *Status* field of the queue head is set to one.

On entry to this state, the host controller executes a few pre-operations, then checks some pre-condition criteria before committing to executing a transaction for the queue head.

The pre-operations performed and the pre-condition criteria depend on whether the queue head is an interrupt endpoint. The host controller can determine that a queue head is an interrupt queue head when the queue head's *S-mask* field contains a non-zero value. It is the responsibility of software to ensure the *S-mask* field is appropriately initialized based on the transfer type. There are other criteria that must be met if the *EPS* field indicates that the endpoint is a low- or full-speed endpoint, see [Split Transactions for Asynchronous Transfers](#) and [Split Transaction Interrupt](#).

#### 11.4.4.3.10.3.1 Interrupt Transfer Pre-condition Criteria

If the queue head is for an interrupt endpoint (for example, non-zero *S-mask* field), then the FRINDEX[2:0] field must identify a bit in the *S-mask* field that has one in it.

For example, an *S-mask* value of 00100000b would evaluate to true only when FRINDEX[2:0] is equal to 101b. If this condition is met then the host controller considers this queue head for a transaction.

#### 11.4.4.3.10.3.2 Asynchronous Transfer Pre-operations and Pre-condition Criteria

If the queue head is not for an interrupt endpoint (for example, zero *S-mask* field), then the host controller performs one pre-operation and then evaluates one pre-condition criteria.

The pre-operation is:

Checks the Nak counter reload state ([Operational Model for Nak Counter](#)). It may be necessary for the host controller to reload the Nak Counter field. The reload is performed at this time.

The pre-condition evaluated is:

- Whether or not the *NakCnt* field has been reloaded, the host controller checks the value of the *NakCnt* field in the queue head. If *NakCnt* is non-zero, or if the *Reload Nak Counter* field is zero, then the host controller considers this queue head for a transaction.

## 11.4.4.3.10.3.3 Transfer Type Independent Pre-operations

Regardless of the transfer type, the host controller always performs at least one pre-operation and evaluates one pre-condition. The pre-operation is:

- A host controller internal transaction (down) counter *qHTransactionCounter* is loaded from the queue head's *Mult* field. A host controller implementation is allowed to ignore this for queue heads on the asynchronous list. It is mandatory for interrupt queue heads. Software should ensure that the *Mult* field is set appropriately for the transfer type.

The pre-conditions evaluated are:

- The host controller determines whether there is enough time in the micro-frame to complete this transaction (see [Transaction Fit - A Best-Fit Approximation Algorithm](#) for an example evaluation method). If there is not enough time to complete the transaction, the host controller exits this state.
- If the value of *qHTransactionCounter* for an interrupt endpoint is zero, then the host controller exits this state.

When the pre-operations are complete and pre-conditions are met, the host controller sets the *Reclamation* bit in the USBSTS register to one and then begins executing one or more transactions using the endpoint information in the queue head. The host controller iterates *qHTransactionCounter* times in this state executing transactions. After each transaction is executed, *qHTransactionCounter* is decremented by one. The host controller exits this state when one of the following events occurs:

- The *qHTransactionCounter* decrements to zero, or
- The endpoint responds to the transaction with any handshake other than an ACK,<sup>4</sup> or
- The transaction experiences a transaction error, or
- The *Active* bit in the queue head goes to zero, or
- There is not enough time in the micro-frame left to execute the next transaction (see [Transaction Fit - A Best-Fit Approximation Algorithm](#) ) for example method for implementing the frame boundary test).

#### NOTE

For a high-bandwidth interrupt OUT endpoint, the host controller may optionally immediately retry the transaction if it fails.

The results of each transaction is recorded in the on-chip overlay area. If data was successfully moved during the transaction, the transfer state in the overlay area is advanced. To advance queue head's transfer state, the *Total Bytes to Transfer* field is decremented by the number of bytes moved in the transaction, the data toggle bit (*dt*) is toggled, the current page offset is advanced to the next appropriate value (for example,

advanced by the number of bytes successfully moved), and the *C\_Page* field is updated to the appropriate value (if necessary). See [Buffer Pointer List Use for Data Streaming with qTDs](#) .

### NOTE

The *Total Bytes To Transfer* field may be zero when all the other criteria for executing a transaction are met. When this occurs, the host controller executes zero-length transaction to the endpoint. If the *PID\_Code* field indicates an IN transaction and the device delivers data, the host controller detects a packet babble condition, set the *babble* and *halted* bits in the *Status* field, set the *Active* bit to zero, write back the results to the source qTD, then exit this state.

In the event an IN token receives a data PID mismatch response, the host controller must ignore the received data (for example not advance the transfer state for the bytes received). Additionally, if the endpoint is an interrupt IN, then the host controller must record that the transaction occurred (for example, decrement *qHTransactionCounter*). It is recommended (but not required) the host controller continue executing transactions for this endpoint if the resultant value of *qHTransactionCounter* is greater than one.

If the response to the IN bus transaction is a Nak (or Nyet) and *RL* is non-zero, *NakCnt* is decremented by one. If *RL* is zero, then no write-back by the host controller is required (for a transaction receiving a Nak or Nyet response and the value of *CErr* did not change). Software should set the *RL* field to zero if the queue head is an interrupt endpoint. Host controller hardware is not required to enforce this rule or operation.

After the transaction has finished and the host controller has completed the post processing of the results (advancing the transfer state and possibly *NakCnt*, the host controller writes back the results of the transaction to the queue head's overlay area in main memory).

The number of bytes moved during an IN transaction depends on how much data the device endpoint delivers. The maximum number of bytes a device can send is *MaximumPacket Size*. The number of bytes moved during an OUT transaction is either *Maximum Packet Length* bytes or *Total Bytes to Transfer*, whichever is less.

If there was a transaction error during the transaction, the transfer state (as defined above) is not advanced by the host controller. The *CErr* field is decremented by one and the status field is updated to reflect the type of error observed. Transaction errors are summarized in [Transaction Error](#) .

The following events causes the host controller to clear the *Active* bit in the queue head's overlay status field. When the *Active* bit transitions from one to zero, the transfer in the overlay is considered complete. The reason for the transfer completion (clearing the *Active* bit) determines the next state.

- *CErr* field decrements to zero. When this occurs the *Halted* bit is set to one and *Active* is set to zero. This results in the hardware not advancing the queue and the pipe halts. Software must intercede to recover.
- The device responds to the transaction with a STALL PID. When this occurs, the *Halted* bit is set to one and the *Active* bit is set to zero. This results in the hardware not advancing the queue and the pipe halts. Software must intercede to recover.
- The *Total Bytes to Transfer* field is zero after the transaction completes.
  - For a zero length transaction, it was zero before the transaction was started. When this condition occurs, the *Active* bit is set to zero.
- The PID code is an IN, and the number of bytes moved during the transaction is less than the *Maximum Packet Length*. When this occurs, the *Active* bit is set to zero and a short packet condition exists. The short-packet condition is detected during the Advance Queue state. Refer to [Split Transactions](#) for additional rules for managing low- and full-speed transactions.

With the exception of a NAK response (when *RL* field is zero), the host controller always writes the results of the transaction back to the overlay area in main memory. This includes when the transfer completes. For a high-speed endpoint, the queue head information written back includes minimally the following fields: The *PID Code* field indicates an IN and the device sends more than the expected number of bytes (for example *Maximum Packet Length* or *Total Bytes to Transfer* bytes, whichever is less) (for example a packet babble). This results in the host controller setting the *Halted* bit to one.

- NakCnt, dt, Total Bytes to Transfer, C\_Page, Status, CERR, and Current Offset

For a low- or full-speed device the queue head information written back also includes the fields:

- C-prog-mask, FrameTag and S-bytes.

The duration of this state depends on the time it takes to complete the transaction(s) and the status write to the overlay is committed.

#### 11.4.4.3.10.3.4 Halting a Queue Head

A halted endpoint is defined only for the transfer types that are managed through queue heads (control, bulk and interrupt).

The following events indicate that the endpoint has reached a condition where no more activity can occur without intervention from the driver:

- An endpoint may return a STALL handshake during a transaction,
- A transaction had three consecutive error conditions, or
- A Packet Babble error occurs on the endpoint.

When any of these events occur (for a queue head) the Host Controller halts the queue head and set the USBERRINT status bit in the USB\_n\_USBSTS register to one. To halt the queue head, the *Active* bit is set to zero and the *Halted* bit is set to one. There may be other error status bits that are set when a queue is halted. The host controller always writes back the overlay area to the source qTD when the transfer is complete, regardless of the reason (normal completion, short packet or halt). The host controller does not advance the transfer state on a transaction that results in a *Halt* condition (for example no updates necessary for *Total Bytes to Transfer*, *C\_Page*, *Current Offset*, and *dt*). The host controller must update *CErr* as appropriate. When a queue head is halted, the *USB Error Interrupt* bit in the USB\_n\_USBSTS register is set to one. If the *USB Error Interrupt Enable* bit in the USB\_n\_USBINTR register is set to one, a hardware interrupt is generated at the next interrupt threshold.

#### 11.4.4.3.10.3.5 Asynchronous Schedule Park Mode

Asynchronous Schedule Park mode is a special execution mode that can be enabled by system software, where the host controller is permitted to execute more than one bus transaction from a high-speed queue head in the Asynchronous schedule before continuing horizontal traversal of the Asynchronous schedule.

This feature has no effect on queue heads or other data structures in the Periodic schedule. This feature is similar in intent as the *Mult* feature that is used in the Periodic schedule. Where-as the *Mult* feature is a characteristic that is tunable for each endpoint; park-mode is a policy that is applied to all high-speed queue heads in the asynchronous schedule. It is essentially the specification of an iterator for consecutive bus transactions to the same endpoint. All of the rules for managing bus transactions and the results of those as defined in [Execute Transaction](#) apply. This feature merely specifies how many consecutive times the host controller is permitted to execute from the same queue head before moving to the next queue head in the Asynchronous List. This feature should allow the host controller to attain better bus utilization for those devices that are capable of moving data at maximum rate, while at the same time providing a fair service to all endpoints.

A host controller exports its capability to support this feature to system software by setting the *Asynchronous Schedule Park Capability* bit in the USB\_n\_HCCPARAMs register to one. This information keys system software that the *Asynchronous Schedule Park Mode Enable* and *Asynchronous Schedule Park Mode Count* fields in the USB\_n\_USBCMD register are modifiable. System software enables the feature by writing a one to the *Asynchronous Schedule Park Mode Enable* bit.

When park-mode is not enabled (for example *Asynchronous Schedule Park Mode Enable* bit in the USB\_n\_USBCMD register is zero), the host controller must not execute more than one bus transaction per high-speed queue head, per traversal of the asynchronous schedule. When park-mode is enabled, the host controller must not apply the feature to a queue head whose *EPS* field indicates a Low/Full-speed device (for example only one bus transaction is allowed from each Low/Full-speed queue head per traversal of the asynchronous schedule). Park-mode may only be applied to queue heads in the Asynchronous schedule whose *EPS* field indicates that it is a high-speed device.

The host controller must apply park mode to queue heads whose *EPS* field indicates a high-speed endpoint. The maximum number of consecutive bus transactions a host controller may execute on a high-speed queue head is determined by the value in the *Asynchronous Schedule Park Mode Count* field in the USB\_n\_USBCMD register. Software must not set *Asynchronous Schedule Park Mode Enable* bit to one and also set *Asynchronous Schedule Park Mode Count* field to zero. The resulting behavior is not defined. An example behavioral example describes the operational requirements for the host controller implementing park-mode. This feature does not affect how the host controller handles the bus transaction as defined in [Execute Transaction](#) . It only effects how many consecutive bus transactions for the current queue head can be executed. All boundary conditions, error detection and reporting applies as usual. This feature is similar in concept to the use of the *Mult* field for high-bandwidth Interrupt for queue heads in the Periodic Schedule.

The host controller effectively loads an internal down-counter *PM-Count* from *Asynchronous Schedule Park Mode Count* when *Asynchronous Schedule Park Mode Enable* bit is one, and a high-speed queue head is first fetched and meets all the criteria for executing a bus transaction. After the bus transaction, *PM-Count* is decremented. The host controller may continue to execute bus transactions from the current queue head until *PM-Count* goes to zero, an error is detected, the buffer for the current transfer is exhausted or the endpoint responds with a flow-control or STALL handshake.

The following table summarizes the responses that effect whether the host controller continues with another bus transaction for the current queue head.

**Table 11-99. Actions for Park Mode, based on Endpoint Response and Residual Transfer State**

PID	Endpoint Response	Transfer State after Transaction		Action
		PM-Count	Bytes to Transfer	
IN	DATA[0,1] w/Maximum Packet sized data	Not zero	Not Zero	Allowed to perform another bus transaction. <sup>1, 2</sup>
		Not zero	Zero	Retire qTD and move to next QH
		Zero	Don't care	Move to next QH.

Table continues on the next page...

**Table 11-99. Actions for Park Mode, based on Endpoint Response and Residual Transfer State (continued)**

	DATA[0,1] w/short packet	Don't care	Don't care	Retire qTD and move to next QH.
	NAK	Don't care	Don't care	Move to next QH.
	STALL, XactErr	Don't care	Don't care	Move to next QH.
OUT	ACK	Not zero	Not Zero	Allowed to perform another bus transaction. <sup>2</sup>
		Not zero	Zero	Retire qTD and move to next QH
		Zero	Don't care	Move to next QH.
	NYET, NAK	Don't care	Don't care	Move to next QH.
	STALL, XactErr	Don't care	Don't care	Move to next QH
PING	ACK	Not Zero	Not Zero	Allowed to perform another bus transaction. <sup>2</sup>
	NAK	Don't care	Don't care	Move to next QH
	STALL, XactErr	Don't care	Don't care	Move to next QH

1. The host controller may continue to execute bus transactions from the current high-speed queue head (if *PM-Count* is not equal to zero), if a PID mismatch is detected (for example expected DATA1 and received DATA0, or visa-versa).
2. This specification does not *require* that the host controller execute another bus transaction when *PM-Count* is non-zero. Implementations are encouraged to make appropriate complexity and performance trade-offs.

#### 11.4.4.3.10.4 Write Back qTD

This state is entered from the Execute Transaction state when the *Active* bit is set to zero.

The source data for the write-back is the transfer results area of the queue head overlay area (see [Table 11-99](#)).

The host controller uses the *Current qTD Pointer* field as the target address for the qTD.

The queue head transfer result area is written back to the transfer result area of the target qTD. This state is also referred to as: qTD retirement. The fields that must be written back to the source qTD include *Total Bytes to Transfer*, *Cerr*, and *Status*.

The duration of this state depends on when the qTD write-back is committed.

#### 11.4.4.3.10.5 Follow Queue Head Horizontal Pointer

The host controller must use the horizontal pointer in the queue head to the next schedule data structure when any of the following conditions exist:

- If the *Active* bit is one on exit from the Execute Transaction state, or
- When the host controller exits the Write Back qTD state, or

- If the Advance Queue state fails to advance the queue because the target qTD is not active, or
- If the *Halted* bit is one on exit from the Fetch QH state.

There is no functional requirement that the host controller wait until the current transaction is complete before using the horizontal pointer to read the next linked data structure. However, it must wait until the current transaction is complete before executing the next data structure.

#### 11.4.4.3.10.6 Buffer Pointer List Use for Data Streaming with qTDs

A qTD has an array of buffer pointers, which is used to reference the data buffer for a transfer. This specification requires that the buffer associated with the transfer be *virtually contiguous*.

This means: if the buffer spans more than one physical page, it must obey the following rules (the figure below illustrates an example):

- The first portion of the buffer must begin at some offset in a page and extend through the end of the page.
- The remaining buffer cannot be allocated in small chunks scattered around memory. For each 4 K chunk beyond the first page, each buffer portion matches to a full 4 K page. The final portion, which may only be large enough to occupy a portion of a page, must start at the top of the page and be contiguous within that page.

The buffer pointer list in the qTD is long enough to support a maximum transfer size of 20 K bytes. This case occurs when all five buffer pointers are used and the first offset is zero. A qTD handles a 16 Kbyte buffer with any starting buffer alignment.

The host controller uses the field *C\_Page* field as an index value to determine which buffer pointer in the list should be used to start the current transaction. The host controller uses a different buffer pointer for each physical page of the buffer. This is always true, even if the buffer is physically contiguous.

The host controller must detect when the current transaction spans a page boundary and automatically move to the next available buffer pointer in the page pointer list. The next available pointer is reached by incrementing *C\_Page* and pulling the next page pointer from the list. Software must ensure there are sufficient buffer pointers to move the amount of data specified in the *Bytes to Transfer* field.

The following figure illustrates a nominal example of how System software would initialize the buffer pointers list and the *C\_Page* field for a transfer size of 16383 bytes. *C\_Page* is set to zero. The upper 20-bits of Page 0 references the start of the physical

page. *Current Offset* (the lower 12-bits of queue head Dword 7) holds the offset in the page for example 2049 (for example 4096-2047). The remaining page pointers are set to reference the beginning of each subsequent 4 K page.

**Figure 11-77. Example Mapping of qTD Buffer Pointers to Buffer Pages**

For the first transaction on the qTD (assuming a 512-byte transaction), the host controller uses the first buffer pointer (page 0 because *C\_Page* is set to zero) and concatenates the *Current Offset* field. The 512 bytes are moved during the transaction, the *Current Offset* and *Total Bytes to Transfer* are adjusted by 512 and written back to the queue head working area.

During the 4<sup>th</sup> transaction, the host controller needs 511 bytes in page 0 and one byte in page 1. The host controller increments *C\_Page* (to 1) and use the page 1 pointer to move the final byte of the transaction. After the 4<sup>th</sup> transaction, the active page pointer is the page 1 pointer and *Current Offset* has rolled to one, and both are written back to the overlay area. The transactions continue for the rest of the buffer, with the host controller automatically moving to the next page pointer (that is *C\_Page*) when necessary. The three conditions for how the host controller handles *C\_Page*:

- The current transaction does not span a page boundary. The value of *C\_Page* is not adjusted by the host controller.

- The current transaction does span a page boundary. The host controller must detect the page cross condition and advance to the next buffer while streaming data to/from the USB.
- The current transaction completes on a page boundary (that is the last byte moved for the current transaction is the last byte in the page for the current page pointer). The host controller must increment *C\_Page* before writing back status for the transaction.

**NOTE**

The only valid adjustment the host controller may make to *C\_Page* is to increment by one.

**11.4.4.3.10.7 Adding Interrupt Queue Heads to the Periodic Schedule**

The link path(s) from the periodic frame list to a queue head establishes in which frames a transaction can be executed for the queue head. Queue heads are linked into the periodic schedule so they are polled at the appropriate rate.

System software sets a bit in a queue head's *S-Mask* to indicate which micro-frame within 1 msec period a transaction should be executed for the queue head. Software must ensure that all queue heads in the periodic schedule have *S-Mask* set to a non-zero value. An *S-mask* with zero value in the context of the periodic schedule yields undefined results.

If the desired poll rate is greater than one frame, system software can use a combination of queue head linking and *S-Mask* values to spread interrupts of equal poll rates through the schedule so that the periodic bandwidth is allocated and managed in the most efficient manner possible. Some examples are illustrated in the following table.

**Table 11-100. Example Periodic Reference Patterns for Interrupt Transfers with 2ms Poll Rate**

Frame # Reference Sequence	Description
0, 2, 4, 6, 8, and so on <i>S-Mask</i> = 01h	A queue head for the <i>bInterval</i> of 2 msec (16 micro-frames) is linked into the periodic schedule so that it is reachable from the periodic frame list locations indicated in the previous column. In addition, the <i>S-Mask</i> field in the queue head is set to 01h, indicating that the transaction for the endpoint should be executed on the bus during micro-frame 0 of the frame.
0, 2, 4, 6, 8, and so on <i>S-Mask</i> = 02h	Another example of a queue head with a <i>bInterval</i> of 2 msec is linked into the periodic frame list at exactly the same interval as the previous example. However, the <i>S-Mask</i> is set to 02h indicating that the transaction for the endpoint should be executed on the bus during micro-frame 1 of the frame.

### 11.4.4.3.10.8 Managing Transfer Complete Interrupts from Queue Heads

The host controller sets an interrupt to be signaled at the next interrupt threshold when the completed transfer (qTD) has an *Interrupt on Complete (IOC)* bit set to one, or whenever a transfer (qTD) completes with a short packet.

If system software needs multiple qTDs to complete a client request (that is like a control transfer) the intermediate qTDs do not require interrupts. System software may only need a single interrupt to notify it that the complete buffer has been transferred. System software may set IOC's to occur more frequently. A motivation for this may be that it wants early notification so that interface data structures can be re-used in a timely manner.

### 11.4.4.3.11 Ping Control

USB 2.0 defines an addition to the protocol for high-speed devices called Ping. Ping is required for all USB 2.0 High-speed bulk and control endpoints.

Ping is not allowed for a split-transaction stream. This extension to the protocol eliminates the bad side-effects of Naking OUT endpoints. The *Status* field has a *Ping State* bit, which the host controller uses to determine the *next* actual PID it uses in the next transaction to the endpoint (see the table below).

The Ping State bit is only managed by the host controller for queue heads that meet the following criteria:

- Queue head is not an interrupt and
- *EPS* field equals High-Speed and
- *PIDCode* field equals OUT

The following table illustrates the state transition table for the host controller's responsibility for maintaining the PING protocol. Refer to Chapter 8 in the USB Specification Revision 2.0 for detailed description on the Ping protocol.

**Table 11-101. Ping Control State Transition Table**

Event	Host	Device	Next
Current	Host	Device	Next
Do Ping	PING	Nak	Do Ping
Do Ping	PING	Ack	Do OUT
Do Ping	PING	XactErr <sup>1</sup>	Do Ping
Do Ping	PING	Stall	N/C <sup>2</sup> Do
OUT	OUT	Nak	Do Ping
Do OUT	OUT	Nyet	Do Ping
Do OUT	OUT	Ack	Do OUT

*Table continues on the next page...*

**Table 11-101. Ping Control State Transition Table (continued)**

Do OUT	OUT	XactErr <sup>1</sup>	Do Ping
Do OUT	OUT	Stall	N/C <sup>2</sup>

1. Transaction Error (XactErr) is any time the host misses the handshake.
2. No transition change required for the Ping State bit. The Stall handshake results in the endpoint being halted (for example Active set to zero and Halt set to one). Software intervention is required to restart queue. 3 A Nyet response to an OUT means that the device has accepted the data, but cannot receive any more at this time. Host must advance the transfer state and additionally, transition the Ping State bit to Do Ping. The Ping State bit has the following encoding:

**Table 11-102. Ping State bit Encoding**

Value	Meaning
0B	Do OUT The host controller uses an OUT PID during the next bus transaction to this endpoint.
1B	Do Ping The host controller uses a PING PID during the next bus transaction to this endpoint.

The defined ping protocol (see USB 2.0 Specification, Chapter 8) allows the host to be *imprecise* on the initialization of the ping protocol (that is start in *Do OUT* when we don't know whether there is space on the device or not). The host controller manages the *Ping State* bit. System software sets the initial value in the queue head when it initializes a queue head. The host controller preserves the *Ping State* bit across all queue advancements. This means that when a new qTD is written into the queue head overlay area, the previous value of the *Ping State* bit is preserved.

### 11.4.4.3.12 Split Transactions

USB 2.0 defines extensions to the bus protocol for managing USB 1.x data streams through USB 2.0 Hubs.

This section describes how the host controller uses the interface data structures to manage data streams with full- and low-speed devices, connected below USB 2.0 hub, utilizing the split transaction protocol.

Refer to USB 2.0 Specification for the complete definition of the split transaction protocol. Full- and Low-speed devices are enumerated identically as high-speed devices, but the transactions to the Full- and Low-speed endpoints use the split-transaction protocol on the high-speed bus. The split transaction protocol is an encapsulation of (or wrapper around) the Full- or Low-speed transaction. The high-speed wrapper portion of the protocol is addressed to the USB 2.0 Hub and Transaction Translator below which the Full- or Low-speed device is attached.

The EHCI interface uses dedicated data structures for managing full-speed isochronous data streams (see [Split Transaction Isochronous Transfer Descriptor \(siTD\)](#)). Control, Bulk and Interrupt are managed using the queuing data structures (see [Queue Head](#)). The interface data structures need to be programmed with the device address and the

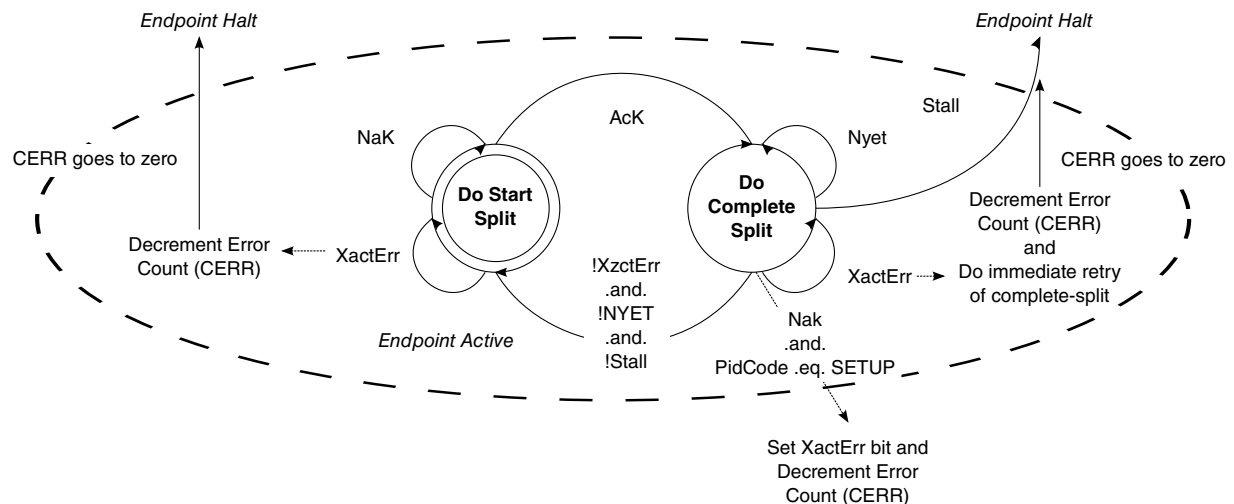

Transaction Translator number of the USB 2.0 Hub operating as the Low-/Full-speed host controller for this link. The following sections describe the details of how the host controller must process and manage the split transaction protocol.

### 11.4.4.3.12.1 Split Transactions for Asynchronous Transfers

A queue head in the asynchronous schedule with an *EPS* field indicating a full-or low-speed device indicates to the host controller that it must use split transactions to stream data for this queue head.

All full-speed bulk and full-, low-speed control are managed through queue heads in the asynchronous schedule.

Software must initialize the queue head with the appropriate device address and port number for the transaction translator that is serving as the full/low-speed host controller for the links connecting the endpoint. Software must also initialize the split transaction state bit (*SplitXState*) to Do-Start-Split. Finally, if the endpoint is a control endpoint, then system software must set the *Control Transfer Type (C)* bit in the queue head to one. If this is not a control transfer type endpoint, the *C* bit must be initialized by software to be zero. This information is used by the host controller to properly set the Endpoint Type (ET) field in the split transaction bus token. When the *C* bit is zero, the split transaction token's ET field is set to indicate a bulk endpoint. When the *C* bit is one, the split transaction token's ET field is set to indicate a control endpoint. Refer to Chapter 8 of USB Specification Revision 2.0 for details.

**Figure 11-78. Host Controller Asynchronous Schedule Split-Transaction State Machine**

#### 11.4.4.3.12.1.1 Asynchronous - Do Start Split

This is the state which software must initialize a full- or low-speed asynchronous queue head. This state is entered from the Do Complete Split state only after a complete-split transaction receives a valid response from the transaction translator that is not a Nyet handshake.

For queue heads in this state, the host controller executes a start-split transaction to the appropriate transaction translator. If the bus transaction completes without an error and *PidCode* indicates an IN or OUT transaction, then the host controller reloads the error counter (*CErr*). If it is a successful bus transaction and the *PidCode* indicates a SETUP, the host controller does not reload the error counter. If the transaction translator responds with a Nak, the queue head is left in this state, and the host controller proceeds to the next queue head in the asynchronous schedule.

If the host controller times out the transaction (no response, or bad response) the host controller decrements *Cerr* and proceeds to the next queue head in the asynchronous schedule.

#### 11.4.4.3.12.1.2 Asynchronous - Do Complete Split

This state is entered from the Do Start Split state only after a start-split transaction receives an Ack handshake from the transaction translator.

For queue heads in this state, the host controller executes a complete-split transaction to the appropriate transaction translator. If the transaction translator responds with a Nyet handshake, the queue head is left in this state, the error counter is reset and the host controller proceeds to the next queue head in the asynchronous schedule. When a Nyet handshake is received for a bus transaction where the queue head's *PidCode* indicates an IN or OUT, the host controller reloads the error counter (*CErr*). When a Nyet handshake is received for a complete-split bus transaction where the queue head's *PidCode* indicates a SETUP, the host controller must not adjust the value of *CErr*.

Independent of *PIDCode*, the following responses have the effects:

- Transaction Error (*XactErr*). Timeout or data CRC failure, and so on. The error counter (*Cerr*) is decremented by one and the complete split transaction is *immediately* retried (if possible). If there is not enough time in the micro-frame to execute the retry, the host controller **MUST** ensure that the next time the host controller begins executing from the Asynchronous schedule, it must begin executing from this queue head. If another start-split (for some other endpoint) is sent to the transaction translator before the complete-split is really completed, the transaction translator could dump the results (which were never delivered to the host). This is why the core specification states the retries must be immediate. A method to accomplish this behavior is to not advance the asynchronous schedule. When the host

controller returns to the asynchronous schedule in the next micro-frame, the first transaction from the schedule is the retry for this endpoint.

If *Cerr* went to zero, the host controller must halt the queue.

- **NAK.** The target endpoint Nak'd the full- or low-speed transaction. The state of the transfer is not advanced and the state is exited. If the *PidCode* is a SETUP, then the Nak response is a protocol error. The *XactErr* status bit is set to one and the *CErr* field is decremented.
- **STALL.** The target endpoint responded with a STALL handshake. The host controller sets the *halt* bit in the status byte, retires the qTD but does not attempt to advance the queue.

If the *PidCode* indicates an IN, then any of following responses are expected:

- **DATA0/1.** On reception of data, the host controller ensures the PID matches the expected data toggle and checks CRC. If the packet is *good*, the host controller advances the state of the transfer, for example move the data pointer by the number of bytes received, decrement *BytesToTransfer* field by the number of bytes received, and toggle the *dt* bit. The host controller then exit this state. The response and advancement of transfer may trigger other processing events, such as retirement of the qTD and advancement of the queue.

If the data sequence PID does not match the expected, the data is ignored, the transfer state is not advanced and this state is exited. If the *PidCode* indicates an OUT/SETUP, then any of following responses are expected:

- **ACK.** The target endpoint accepted the data, so the host controller must advance the state of the transfer. The *Current Offset* field is incremented by *Maximum Packet Length* or *Bytes to Transfer*, whichever is less. The field *Bytes To Transfer* is decremented by the same amount and the data toggle bit (*dt*) is toggled. The host controller then exit this state.
- Advancing the transfer state may cause other processing events such as retirement of the qTD and advancement of the queue (see [Managing Control/Bulk/Interrupt Transfers through Queue Heads](#)).

#### 11.4.4.3.12.2 Split Transaction Interrupt

Split-transaction Interrupt-IN/OUT endpoints are managed through the same data structures used for high-speed interrupt endpoints. They both co-exist in the periodic schedule.

Queue heads/qTDs offer the set of features required for reliable data delivery, which is characteristic to interrupt transfer types. The split-transaction protocol is managed completely within this defined functional transfer framework. For example, for a high-speed endpoint, the host controller visits a queue head, execute a high-speed transaction (if criteria are met) and advance the transfer state (or not) depending on the results of the entire transaction. For low- and full-speed endpoints, the details of the *execution* phase are different (that is takes more than one bus transaction to complete), but the remainder of the operational framework is intact. This means that the transfer advancement, and so on, occurs as defined in [Managing Control/Bulk/Interrupt Transfers through Queue Heads](#), but only occurs on the completion of a split transaction.

#### 11.4.4.3.12.2.1 Split Transaction Scheduling Mechanisms for Interrupt

Full- and low-speed Interrupt queue heads have an *EPS* field indicating full- or low-speed and have a non-zero *S-mask* field.

The host controller can detect this combination of parameters and assume the endpoint is a periodic endpoint. Low- and full-speed interrupt queue heads require the use of the split transaction protocol. The host controller sets the Endpoint Type (ET) field in the split token to indicate the transaction is an interrupt. These transactions are managed through a transaction translator's periodic pipeline. Software should not set these fields to indicate the queue head is an interrupt unless the queue head is used in the periodic schedule.

System software manages the per/transaction translator periodic pipeline by budgeting and scheduling exactly during which micro-frames the start-splits and complete-splits for each endpoint occurs. The characteristics of the transaction translator are such that the high-speed transaction protocol must execute during explicit micro-frames, or the data or response information in the pipeline is lost.

The following figure illustrates the general scheduling boundary conditions that are supported by the EHCI periodic schedule and queue head data structure. The S and <sup>C</sup>X labels indicate micro-frames where software can schedule start-splits and complete splits (respectively).

**Figure 11-79. Split Transaction, Interrupt Scheduling Boundary Conditions**

The scheduling cases are:

- Case 1: The normal scheduling case is where the entire split transaction is completely bounded by a frame (*H-Frame* in this case).
- Case 2a through Case 2c: The USB 2.0 Hub pipeline rules states clearly, when and how many complete-splits must be scheduled to account for earliest to latest execution on the full/low-speed link. The complete-splits may span the *H-Frame* boundary when the start-split is in micro-frame 4 or later. When this occurs, the *H-Frame* to *B-Frame* alignment requires that the queue head be reachable from consecutive periodic frame list locations. System software cannot build an efficient schedule that satisfies this requirement unless it uses FSTNs.

The figure below illustrates the general layout of the periodic schedule.

**Figure 11-80. General Structure of EHCI Periodic Schedule Utilizing Interrupt Spreading**

The periodic frame list is effectively the leaf level a binary tree, which is always traversed leaf to root. Each level in the tree corresponds to a  $2^N$  poll rate. Software can efficiently manage periodic bandwidth on the USB by *spreading* interrupt queue heads that have the same poll rate requirement across all the available paths from the frame list. For example, system software can schedule eight poll rate 8 queue heads and account for them once in the high-speed bus bandwidth allocation.

When an endpoint is allocated an execution footprint that spans a frame boundary, the queue head for the endpoint must be reachable from consecutive locations in the frame list. An example would be if  $8_{0b}$  where such an endpoint. Without additional support on the interface, to get  $8_{0b}$  reachable at the correct time, software would have to link  $8_1$  to  $8_{0b}$ . It would then have to move  $4_1$  and everything linked after into the same path as  $4_0$ . This upsets the integrity of the binary tree and disallows the use of the spreading technique.

FSTN data structures are used to preserve the integrity of the binary-tree structure and enable the use of the spreading technique. [Host Controller Operational Model for FSTNs](#) defines the hardware and software operational model requirements for using FSTNs.

The following queue head fields are initialized by system software to instruct the host controller when to execute portions of the split-transaction protocol:

- *SplitXState*. This is single bit residing in the *Status* field of a queue head (see [Table 11-79](#)). This bit is used to track the current state of the split transaction.
- *Frame S-mask*. This is a bit-field where-in system software sets a bit corresponding to the micro-frame (within an *H-Frame*) that the host controller should execute a start-split transaction. This is always qualified by the value of the *SplitXState* bit in the *Status* field of the queue head. For example, referring to [Figure 11-79](#), case one, the *S-mask* would have a value of 00000001b indicating that if the queue head is traversed by the host controller, and the *SplitXState* indicates Do\_Start, and the current micro-frame as indicated by FRINDEX[2:0] is 0, then execute a start-split transaction.
- *Frame C-mask*. This is a bit-field where system software sets one or more bits corresponding to the micro-frames (within an *H-Frame*) that the host controller should execute complete-split transactions. The interpretation of this field is always qualified by the value of the *SplitXState* bit in the *Status* field of the queue head. For example, referring to [Figure 11-79](#), case one, the *C-mask* would have a value of 00011100b indicating that if the queue head is traversed by the host controller, and the *SplitXState* indicates Do\_Complete, and the current micro-frame as indicated by FRINDEX[2:0] is 2, 3, or 4, then execute a complete-split transaction. It is software's responsibility to ensure that the translation between *H-Frames* and *B-Frames* is correctly performed when setting bits in *S-mask* and *C-mask*

#### 11.4.4.3.12.2.2 Host Controller Operational Model for FSTNs

The FSTN data structure is used to manage Low/Full-speed interrupt queue heads that need to be reached from consecutive frame list locations (that is boundary cases 2a through 2c).

An FSTN is essentially a *back pointer*, similar in intent to the back pointer field in the siTD data structure (see [siTD Back Link Pointer](#)).

This feature provides software a simple primitive to save a schedule position, redirect the host controller to traverse the necessary queue heads in the previous frame, then restore the original schedule position and complete normal traversal.

The four components to the use of FSTNs:

- FSTN data structure.
- A *Save Place* indicator. This is always an FSTN with its *Back Path Link Pointer.T-bit* set to zero.

- A *Restore* indicator. This is always an FSTN with its *Back Path Link Pointer.T-bit* set to one.
- Host controller FSTN traversal rules.

When the host controller encounters an FSTN during micro-frames 2 through 7 it simply follows the node's *Normal Path Link Pointer* to access the next schedule data structure.

### NOTE

The FSTN's *Normal Path Link Pointer.T-bit* may set to one, which the host controller must interpret as the end of periodic list mark.

When the host controller encounters a *Save-Place* FSTN in micro-frames 0 or 1, it saves the value of the *Normal Path Link Pointer* and set an internal flag indicating that it is executing in *Recovery Path* mode. *Recovery Path* mode modifies the host controller's rules for how it traverses the schedule and limits which data structures is considered for execution of bus transactions. The host controller continues executing in *Recovery Path* mode until it encounters a *Restore* FSTN or it determines that it has reached the end of the micro-frame (see details in the list below).

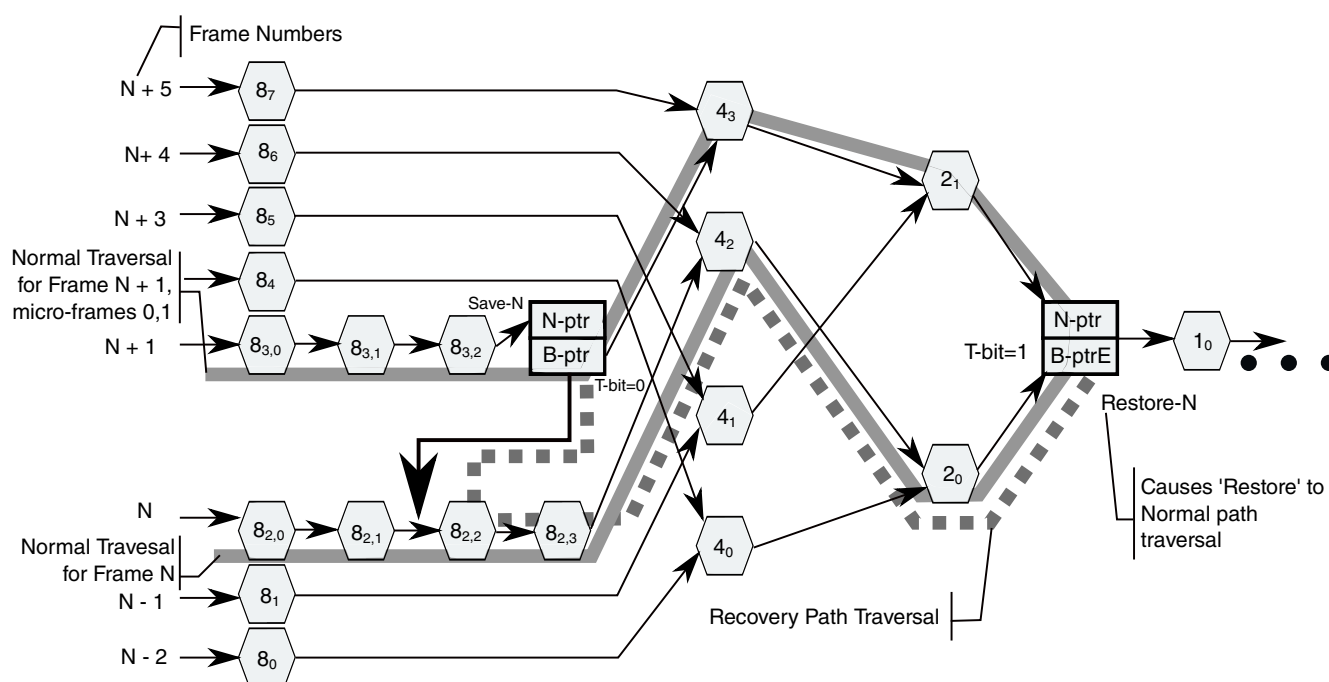

The rules for schedule traversal and limited execution while in *Recovery Path* mode are:

- Always follow the *Normal Path Link Pointer* when it encounters an FSTN that is a *Save-Place* indicator. The host controller must not recursively follow *Save-Place* FSTNs. Therefore, while executing in *Recovery Path* mode, it must never follow an FSTN's *Back Path Link Pointer*.
- Do not process an siTD or, iTD data structure. Simply follow its *Next Link Pointer*.
- Do not process a QH (Queue Head) whose *EPS* field indicates a high-speed device. Simply follow its *Horizontal Link Pointer*.
- When a QH's *EPS* field indicates a Full/Low-speed device, the host controller considers only it for execution if its *SplitXState* is DoComplete (note: this applies whether the *PID Code* indicates an IN or an OUT). See [Execute Transaction](#) and [Tracking Split Transaction Progress for Interrupt Transfers](#) for a complete list of additional conditions that must be met in general for the host controller to issue a bus transaction.
  - The host controller must not execute a Start-split transaction while executing in *Recovery Path* mode. See [Periodic Isochronous - Do Complete Split](#) for special handling when in *Recovery Path* mode.
- Stop traversing the *recovery path* when it encounters an FSTN that is a *Restore* indicator. The host controller unconditionally uses the saved value of the *Save-Place* FSTN's *Normal Path Link Pointer* when returning to the normal path traversal. The

host controller must clear the context of executing a *Recovery Path* when it restores schedule traversal to the *Save-Place* FSTN's *Normal Path Link Pointer*.

- If the host controller determines that there is not enough time left in the micro-frame to complete processing of the periodic schedule, it abandons traversal of the recovery path, and clears the context of executing a recovery path. The result is that at the start of the next consecutive micro-frame, the host controller starts traversal at the frame list.

An example traversal of a periodic schedule that includes FSTNs is illustrated in the following figure.

**Figure 11-81. Example Host Controller Traversal of Recovery Path via FSTNs**

In frame N+1 (micro-frames 0 and 1), when the host controller encounters *Save-Path* FSTN (*Save-N*), it observes that *Save-N*.*Back Path Link Pointer*.*T-bit* is zero (definition of a *Save-Path* indicator). The host controller saves the value of *Save-N*.*Normal Path Link Pointer* and follows *Save-N*.*Back Path Link Pointer*. At the same time, it sets an internal flag indicating that it is now in *Recovery Path* mode (the recovery path is annotated in the figure above with a large dashed line). The host controller continues traversing data structures on the recovery path and executing only those bus transactions as noted above, on the recovery path until it reaches *Restore* FSTN (*Restore-N*). *Restore-N*.*Back Path Link Pointer*.*T-bit* is set to one (definition of a *Restore* indicator), so the host controller exits *Recovery Path* mode by clearing the internal *Recovery Path* mode flag and commences (restores) schedule traversal using the saved value of the *Save-Place* FSTN's *Normal Path Link Pointer* (for example *Save-N*.*Normal Path Link Pointer*). The nodes traversed during these micro-frames include: {83,0, 83,1, 83,2, *Save-A*, 82,2, 82,3, 42,

$2_0$ , Restore-N,  $4_3$ ,  $2_1$ , Restore-N,  $1_0 \dots$ }. The nodes on the recovery-path are in bold. In frame N (micro-frames 0-7), for this example, the host controller traverses all of the schedule data structures utilizing the *Normal Path Link Pointers* in any FSTNs it encounters. This is because the host controller has not yet encountered a *Save-Place* FSTN so it not executing in *Recovery Path* mode. When it encounters the *Restore* FSTN, (Restore-N), during micro-frames 0 and 1, it uses Restore-N.Normal Path Link Pointer to traverse to the next data structure (that is normal schedule traversal). This is because the host controller must use a Restore FSTN's *Normal Path Link Pointer* when not executing in a *Recovery-Path* mode. The nodes traversed during frame N include:  $\{8_{2,0}$ ,  $8_{2,1}$ ,  $8_{2,2}$ ,  $8_{2,3}$ ,  $4_2$ ,  $2_0$ , Restore-N,  $1_0 \dots$ }.

In frame N+1 (micro-frames 2-7), when the host controller encounters Save-Path FSTN Save-N, it unconditionally follows Save-N.Normal Path Link Pointer. The nodes traversed during these micro-frames include:  $\{8_{3,0}$ ,  $8_{3,1}$ ,  $8_{3,2}$ , Save-A,  $4_3$ ,  $2_1$ , Restore-N,  $1_0 \dots$ }.

#### 11.4.4.3.12.2.3 Software Operational Model for FSTNs

Software must create a consistent, coherent schedule for the host controller to traverse.

When using FSTNs, system software must adhere to the following rules:

- Each *Save-Place* indicator requires a matching *Restore* indicator.
  - The *Save-Place* indicator is an FSTN with a valid *Back Path Link Pointer* and *T-bit* equal to zero.
    - *Back Path Link Pointer.Type* field must be set to indicate the referenced data structure is a queue head. The *Restore* indicator is an FSTN with its *Back Path Link Pointer.T-bit* set to one.
  - A *Restore* FSTN may be matched to one or more *Save-Place* FSTNs. For example, if the schedule includes a poll-rate 1 level, then system software only needs to place a *Restore* FSTN at the beginning of this list in order to match all possible *Save-Place* FSTNs.
- If the schedule does not have elements linked at a poll-rate level of one, and one or more *Save-Place* FSTNs are used, then System Software must ensure the *Restore* FSTN's *Normal Path Link Pointer's T-bit* is set to one, as this is used to mark the end of the periodic list.
- When the schedule does have elements linked at a poll rate level of one, a *Restore* FSTN must be the first data structure on the poll rate one list. All traversal paths from the frame list converge on the poll-rate one list. System software must ensure that *Recovery Path* mode is exited before the host controller is allowed to traverse the poll rate level one list.
- A *Save-Place* FSTN's *Back Path Link Pointer* must reference a queue head data structure. The referenced queue head must be reachable from the previous frame list

location. In other words, if the *Save-Place* FSTN is reachable from frame list offset N, then the FSTN's *Back Path Link Pointer* must reference a queue head that is reachable from frame list offset N-1.

Software should make the schedule as efficient as possible. What this means in this context is that software should have no more than one *Save-Place* FSTN reachable in any single frame. Note there is times when two (or more, depending on the implementation) could exist as full/low-speed footprints change with bandwidth adjustments. This could occur, for example when a bandwidth re-balance causes system software to move the *Save-Place* FSTN from one poll rate level to another. During the transition, software must preserve the integrity of the previous schedule until the new schedule is in place.

#### 11.4.4.3.12.2.4 Tracking Split Transaction Progress for Interrupt Transfers

To correctly maintain the data stream, the host controller must be able to detect and report errors where data is lost.

For interrupt-IN transfers, data is lost when it makes it into the USB 2.0 hub, but the USB 2.0 host system is unable to get it from the USB 2.0 Hub and into the system before it expires from the transaction translator pipeline.

When a lost data condition is detected, the queue must be halted, thus signaling system software to recover from the error. A data-loss condition exists whenever a start-split is issued, accepted and successfully executed by the USB 2.0 Hub, but the complete-splits get unrecoverable errors on the high-speed link, or the complete-splits do not occur at the correct times. One reason complete-splits might not occur at the right time would be due to host-induced system hold-offs that cause the host controller to miss bus transactions because it cannot get timely access to the schedule in system memory.

The same condition can occur for an interrupt-OUT, but the result is not an endpoint halt condition, but rather effects only the progress of the transfer. The queue head has the following fields to track the progress of each split transaction. These fields are used to keep incremental state about which (and when) portions have been executed.

- *C-prog-mask*. This is an eight-bit bit-vector where the host controller keeps track of which complete-splits have been executed. Due to the nature of the Transaction Translator periodic pipeline, the complete-splits need to be executed in-order. The host controller needs to detect when the complete-splits have not been executed in order. This can only occur due to system hold-offs where the host controller cannot get to the memory-based schedule. *C-prog-mask* is a simple bit-vector that the host controller sets one of the *C-prog-mask* bits for each complete-split executed. The bit position is determined by the micro-frame number in which the complete-split was executed. The host controller always checks *C-prog-mask* before executing a

- complete-split transaction. If the previous complete-splits have not been executed then it means one (or more) have been skipped and data has potentially been lost.
- *FrameTag*. This field is used by the host controller during the complete-split portion of the split transaction to tag the queue head with the frame number (*H-Frame* number) when the next complete split must be executed.
  - *S-bytes*. This field can be used to store the number of data payload bytes sent during the start-split (if the transaction was an OUT). The *S-bytes* field must be used to accumulate the data payload bytes received during the complete-splits (for an IN).

#### 11.4.4.3.12.2.5 Split Transaction Execution State Machine for Interrupt

In the following presentation, all references to micro-frame are in the context of a micro-frame within an *H-Frame*.

>As with asynchronous Full- and Low-speed endpoints, a split-transaction state machine is used to manage the split transaction sequence.

Aside from the fields defined in the queue head for scheduling and tracking the split transaction, the host controller calculates one internal mechanism that is also used to manage the split transaction. The internal calculated mechanism is:

- *cMicroFrameBit*. This is a single-bit encoding of the current micro-frame number. It is an eight-bit value calculated by the host controller at the beginning of every micro-frame. It is calculated from the three least significant bits of the *FRINDEX* register (that is,  $cMicroFrameBit = (1 \text{ shifted-left}(FRINDEX[2:0]))$ ). The *cMicroFrameBit* has at most one bit asserted, which always corresponds to the current micro-frame number. For example, if the current micro-frame is 0, then *cMicroFrameBit* will equal 00000001b. The variable *cMicroFrameBit* is used to compare against the *S-mask* and *C-mask* fields to determine whether the queue head is marked for a start- or complete-split transaction for the current micro-frame.

The following figure illustrates the state machine for managing a complete interrupt split transaction. There are two phases to each split transaction. The first is a single start-split transaction, which occurs when the *SplitXState* is at *Do\_Start* and the single bit in *cMicroFrameBit* has a corresponding bit active in *QH.S-mask*. The transaction translator does not acknowledge the receipt of the periodic start-split, so the host controller unconditionally transitions the state to *Do\_Complete*. Due to the available jitter in the transaction translator pipeline, there will be more than one complete-split transaction scheduled by software for the *Do\_Complete* state. This translates simply to the fact that there are multiple bits set to a one in the *QH.C-mask* field.

The host controller keeps the queue head in the *Do\_Complete* state until the split transaction is complete (see definition below), or an error condition triggers the *three-strikes-rule* (for example, after the host tries the same transaction three times, and each

encounters an error, the host controller will stop retrying the bus transaction and halt the endpoint, thus requiring system software to detect the condition and perform system-dependent recovery).

**Figure 11-82. Split Transaction State Machine for Interrupt**

See Previous Section for the frame tag management rules.

### Periodic Interrupt - Do Start Split

This is the state software must initialize a full- or low-speed interrupt queue head *StartXState* bit. This state is entered from the *Do\_Complete Split* state only after the split transaction is complete. This occurs when one of the following events occur: The transaction translator responds to a complete-split transaction with one of the following:

- **NAK.** A NAK response is a propagation of the full- or low-speed endpoint's NAK response.
- **ACK.** An ACK response is a propagation of the full- or low-speed endpoint's ACK response. Only occurs on an OUT endpoint.
- **DATA 0/1.** Only occurs for INs. Indicates that this is the last of the data from the endpoint for this split transaction.
- **ERR.** The transaction on the low-/full-speed link below the transaction translator had a failure (for example, timeout, bad CRC, etc.).
- **NYET (and Last).** The host controller issued the last complete-split and the transaction translator responded with a NYET handshake. This means that the start-split was not correctly received by the transaction translator, so it never executed a transaction to the full- or low-speed endpoint, see Section [Periodic Isochronous - Do Complete Split](#) for the definition of 'Last'.

Each time the host controller visits a queue head in this state (once within the Execute Transaction state), it performs the following test to determine whether to execute a start-split.

- *QH.S-mask* is bit-wise anded with *cMicroFrameBit*.

If the result is non-zero, then the host controller will issue a start-split transaction. If the *PIDCode* field indicates an IN transaction, the host controller must zero-out the *QH.S-bytes* field. After the split-transaction has been executed, the host controller sets up state in the queue head to track the progress of the complete-split phase of the split transaction. Specifically, it records the expected frame number into *QH.FrameTag* field (see Section ), set *C-prog-mask* to zero (00h), and exits this state. Note that the host controller must not adjust the value of *CErr* as a result of completion of a start-split transaction.

### Periodic Interrupt - Do Complete Split

This state is entered unconditionally from the Do Start Split state after a start-split transaction is executed on the bus. Each time the host controller visits a queue head in this state (once within the Execute Transaction state), it checks to determine whether a complete-split transaction should be executed now.

There are four tests to determine whether a complete-split transaction should be executed.

- Test A. *cMicroFrameBit* is bit-wise anded with *QH.C-mask* field. A non-zero result indicates that software scheduled a complete-split for this endpoint, during this micro-frame.
- Test B. *QH.FrameTag* is compared with the current contents of *FRINDEX[7:3]*. An equal indicates a match.
- Test C. The complete-split progress bit vector is checked to determine whether the previous bit is set, indicating that the previous complete-split was appropriately executed. An example algorithm for this test is provided below:

```
Algorithm Boolean CheckPreviousBit(QH.C-prog-mask, QH.C-mask, cMicroFrameBit)
Begin
-- Return values:
-- TRUE - no error
-- FALSE - error
--
Boolean rvalue = TRUE;
previousBit = cMicroframeBit logical-rotate-right(1)
-- Bit-wise anding previousBit with C-mask indicates
-- whether there was an intent
-- to send a complete split in the previous micro-frame. So,
-- if the
-- 'previous bit' is set in C-mask, check C-prog-mask to
-- make sure it
-- happened.
If (previousBit bitAND QH.C-mask) then
    If not(previousBit bitAND QH.C-prog-mask) then
        rvalue = FALSE;
    End if
End If
-- If the C-prog-mask already has a one in this bit position,
```

```

-- then an aliasing
-- error has occurred. It will probably get caught by the
-- FrameTag Test, but
-- at any rate it is an error condition that as detectable here
-- should not allow
-- a transaction to be executed.
If (cMicroFrameBit bitAND QH.C-prog-mask) then
  rvalue = FALSE;
End if
return (rvalue)
End Algorithm

```

- Test D. Check to see if a start-split should be executed in this micro-frame. Note this is the same test performed in the Do Start Split state (see Section [Periodic Isochronous - Do Start Split](#)). Whenever it evaluates to TRUE and the controller is NOT processing in the context of a *Recovery Path* mode, it means a start-split should occur in this micro-frame. Test D and Test A evaluating to TRUE at the same time is a system software error. Behavior is undefined.

If (A .and. B .and. C .and. not(D)) then the host controller will execute a complete-split transaction. When the host controller commits to executing the complete-split transaction, it updates *QH.C-prog-mask* by bit-ORing with *cMicroFrameBit*. On completion of the complete-split transaction, the host controller records the result of the transaction in the queue head and sets *QH.FrameTag* to the expected *H-Frame* number (see Section ). The effect to the state of the queue head and thus the state of the transfer depends on the response by the transaction translator to the complete-split transaction. The following responses have the effects (note that any responses that result in decrementing of the *CErr* will result in the queue head being halted by the host controller if the result of the decrement is zero):

- NYET (and Last). On each NYET response, the host controller checks to determine whether this is the last complete-split for this split transaction. Last is defined in this context as the condition where all of the scheduled complete-splits have been executed. If it is the last complete-split (with a NYET response), then the transfer state of the queue head is not advanced (never received any data) and this state exited. The transaction translator must have responded to all the complete-splits with NYETs, meaning that the start-split issued by the host controller was not received. The start-split should be retried at the next poll period.
- The test for whether this is the Last complete split can be performed by XOR *QH.C-mask* with *QH.C-prog-mask*. If the result is all zeros then all complete-splits have been executed. When this condition occurs, the *XactErr* status bit is set to a one and the *CErr* field is decremented.
- NYET (and not Last). See above description for testing for Last. The complete-split transaction received a NYET response from the transaction translator. Do not update any transfer state (except for *C-prog-mask* and *FrameTag*) and stay in this state. The host controller must not adjust *CErr* on this response.

- Transaction Error (XactErr). Timeout, data CRC failure, etc. The *CErr* field is decremented and the *XactErr* bit in the *Status* field is set to a one. The complete split transaction is *immediately* retried (if *Cerr* is non-zero). If there is not enough time in the micro-frame to complete the retry and the endpoint is an IN, or *CErr* is decremented to a zero from a one, the queue is halted. If there is not enough time in the micro-frame to complete the retry and the endpoint is an OUT and *CErr* is not zero, then this state is exited (that is, return to Do Start Split). This results in a retry of the entire OUT split transaction, at the next poll period. Refer to Chapter 11 Hubs (specifically the section full- and low-speed Interrupts) in the USB Specification Revision 2.0 for detailed requirements on why these errors must be immediately retried.
- ACK. This can only occur if the target endpoint is an OUT. The target endpoint ACK'd the data and this response is a propagation of the endpoint ACK up to the host controller. The host controller must advance the state of the transfer. The *Current Offset* field is incremented by *Maximum Packet Length* or *Bytes to Transfer*, whichever is less. The field *Bytes To Transfer* is decremented by the same amount. And the data toggle bit (*dt*) is toggled. The host controller will then exit this state for this queue head. The host controller must reload *CErr* with maximum value on this response. Advancing the transfer state may cause other process events such as retirement of the qTD and advancement of the queue (see Section [Managing Control/Bulk/Interrupt Transfers through Queue Heads](#)).
- MDATA. This response will only occur for an IN endpoint. The transaction translator responded with zero or more bytes of data and an MDATA PID. The incremental number of bytes received is accumulated in *QH.S-bytes*. The host controller must not adjust *CErr* on this response.
- DATA0/1. This response may only occur for an IN endpoint. The number of bytes received is added to the accumulated byte count in *QH.S-bytes*. The state of the transfer is advanced by the result and the host controller will exit this state for this queue head.
- Advancing the transfer state may cause other processing events such as retirement of the qTD and advancement of the queue (see Section [Managing Control/Bulk/Interrupt Transfers through Queue Heads](#)).
- If the data sequence PID does not match the expected, the entirety of the data received in this split transaction is ignored, the transfer state is not advanced and this state is exited.
- NAK. The target endpoint Nak'd the full- or low-speed transaction. The state of the transfer is not advanced, and this state is exited. The host controller must reload *CErr* with maximum value on this response.

- **ERR.** There was an error during the full- or low-speed transaction. The ERR status bit is set to a one, *Cerr* is decremented, the state of the transfer is not advanced, and this state is exited.
- **STALL.** The queue is halted (an exit condition of the Execute Transaction state). The status field bits: *Active* bit is set to zero and the *Halted* bit is set to a one and the qTD is retired. Responses which are not enumerated in the list or which are received out of sequence are illegal and may result in undefined host controller behavior. The other possible combinations of tests A, B, C, and D may indicate that data or response was lost. The table below lists the possible combinations and the appropriate action.

**Table 11-103. Interrupt IN/OUT Do Complete Split State Execution Criteria**

Condition	Action	Description
not(A) not(D)	Ignore QHD	Neither a start nor complete-split is scheduled for the current micro-frame. Host controller should continue walking the schedule.
A not(C)	If <i>PIDCode</i> = IN Halt QHD If <i>PIDCode</i> = OUT Retry start-split	Progress bit check failed. These means a complete-split has been missed. There is the possibility of lost data. If <i>PIDCode</i> is an IN, then the Queue head must be halted.  If <i>PIDCode</i> is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not effect <i>CERR</i> .  In either case, set the <i>Missed Micro-frame</i> bit in the status field to a one.
A not(B) C	If <i>PIDCode</i> = IN Halt QHD If <i>PIDCode</i> = OUT Retry start-split	<i>QH.FrameTag</i> test failed. This means that exactly one or more <i>H-Frames</i> have been skipped. This means complete-splits and have missed. There is the possibility of lost data. If <i>PIDCode</i> is an IN, then the Queue head must be halted.  If <i>PIDCode</i> is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not effect <i>CERR</i> .  In either case, set the <i>Missed Micro-frame</i> bit in the status field to a one.
A B C not(D)	Execute complete-split	This is the non-error case where the host controller executes a complete-split transaction.
D	If <i>PIDCode</i> = IN Halt QHD If <i>PIDCode</i> = OUT Retry start-split	This is a degenerate case where the start-split was issued, but all of the complete-splits were skipped and all possible intervening opportunities to detect the missed data failed to fire. If <i>PIDCode</i> is an IN, then the Queue head must be halted.  If <i>PIDCode</i> is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not effect <i>CERR</i> .  In either case, set the <i>Missed Micro-frame</i> bit in the status field to a one. Note: When executing in the context of a <i>Recovery Path</i> mode, the host controller is allowed to process the queue head and take the actions indicated above, or it may wait until the queue head is visited in the

**Table 11-103. Interrupt IN/OUT Do Complete Split State Execution Criteria**

		normal processing mode. Regardless, the host controller must not execute a start-split in the context of a executing in a <i>Recovery Path</i> mode.
--	--	--

### Managing QH.FrameTag Field

The *QH.FrameTag* field in a queue head is completely managed by the host controller. The rules for setting *QH.FrameTag* are simple:

- Rule 1: If transitioning from Do Start Split to Do Complete Split and the current value of *FRINDEX*[2:0] is 6 *QH.FrameTag* is set to *FRINDEX*[7:3] + 1. This accommodates split transactions whose start-split and complete-splits are in different *H-Frames* (case 2a, see [Figure 11-79](#)).
- Rule 2: If the current value of *FRINDEX*[2:0] is 7, *QH.FrameTag* is set to *FRINDEX*[7:3] + 1. This accommodates staying in Do Complete Split for cases 2a, 2b, and 2c ([Figure 11-79](#)).
- Rule 3: If transitioning from Do\_Start Split to Do Complete Split and the current value of *FRINDEX*[2:0] is not 6, or currently in Do Complete Split and the current value of (*FRINDEX*[2:0]) is not 7, *FrameTag* is set to *FRINDEX*[7:3]. This accommodates all other cases ([Figure 11-79](#)).

#### 11.4.4.3.12.2.6 Rebalancing the periodic schedule

System software must occasionally adjust a periodic queue head's S-mask and C-mask fields during operation.

This need occurs when adjustments to the periodic schedule create a new bandwidth budget and one or more queue head's are assigned new execution footprints (that is, new S-mask and C-mask values).

It is imperative that System software must not update these masks to new values in the midst of a split transaction. In order to avoid any race conditions with the update, the EHCI host controller provides a simple assist to system software. System software sets the *Inactivate-on-next-Transaction (I)* bit to a one to signal the host controller that it intends to update the S-mask and C-mask on this queue head. System software will then wait for the host controller to observe the *I-bit* is a one and transition the *Active* bit to a zero. The rules for how and when the host controller sets the *Active* bit to zero are enumerated below:

- If the *Active* bit is a zero, no action is taken. The host controller does not attempt to advance the queue when the *I-bit* is a one.
- If the *Active* bit is a one and the *SplitXState* is DoStart (regardless of the value of *S-mask*), the host controller will simply set *Active* bit to a zero. The host controller is

not required to write the transfer state back to the *current* qTD. Note that if the *S-mask* indicates that a start-split is scheduled for the current micro-frame, the host controller must not issue the start-split bus transaction. It must set the *Active* bit to zero.

System software must save transfer state before setting the *I-bit* to a one. This is required so that it can correctly determine what transfer progress (if any) occurred after the *I-bit* was set to a one and the host controller executed its final bus-transaction and set *Active* to a zero.

After system software has updated the S-mask and C-mask, it must then reactivate the queue head. Because the *Active* bit and the *I-bit* cannot be updated with the same write, system software needs to use the following algorithm to coherently re-activate a queue head that has been stopped via the *I-bit*.

1. Set the *Halted* bit to a one, then
2. Set the *I-bit* to a zero, then
3. Set the *Active* bit to a one and the *Halted* bit to a zero in the same write.

Setting the *Halted* bit to a one inhibits the host controller from attempting to advance the queue between the time the *I-bit* goes to a zero and the *Active* bit goes to a one.

### 11.4.4.3.12.3 Split Transaction Isochronous

Full-speed isochronous transfers are managed using the split-transaction protocol through a USB 2.0 transaction translator in a USB2.0 Hub. The EHCI controller utilizes siTD data structure to support the special requirements of isochronous split-transactions.

This data structure uses the scheduling model of isochronous TDs (iTDD, Section [Isochronous \(High-Speed\) Transfer Descriptor \(iTDD\)](#)) (see Section [Managing Isochronous Transfers Using iTDDs](#) for the operational model of iTDDs) with the contiguous data feature provided by queue heads. This simple arrangement allows a single isochronous scheduling model and adds the additional feature that all data received from the endpoint (per split transaction) must land into a contiguous buffer.

#### 11.4.4.3.12.3.1 Split Transaction Scheduling Mechanisms for Isochronous

Full-speed isochronous transactions are managed through a transaction translator's periodic pipeline. As with full- and low-speed interrupt, system software manages each transaction translator's periodic pipeline by budgeting and scheduling exactly during which micro-frames the start-splits and complete-splits for each full-speed isochronous endpoint occur.

The requirements described in Section [Split Transaction Scheduling Mechanisms for Interrupt](#) apply. The following figure illustrates the general scheduling boundary conditions that are supported by the EHCI periodic schedule. The <sup>S</sup>X and <sup>C</sup>X labels indicate micro-frames where software can schedule start- and complete-splits (respectively). The *H-Frame* boundaries are marked with a large, solid bold vertical line. The *B-Frame* boundaries are marked with a large, bold, dashed line. The bottom of the figure illustrates the relationship of an siTD to the *H-Frame*.

**Figure 11-83. Split Transaction, Isochronous Scheduling Boundary Conditions**

When the endpoint is an isochronous OUT, there are only start-splits, and no complete-splits. When the endpoint is an isochronous IN, there is at most one start-split and one to *N* complete-splits. The scheduling boundary cases are:

- *Case 1:* The entire split transaction is completely bounded by an *H-Frame*. For example: the start-splits and complete-splits are all scheduled to occur in the same *H-Frame*.

- *Case 2a*: This boundary case is where one or more (at most two) complete-splits of a split transaction IN are scheduled across an *H-Frame* boundary. This can only occur when the split transaction has the possibility of moving data in *B-Frame*, micro-frames 6 or 7 (*H-Frame* micro-frame 7 or 0). When an *H-Frame* boundary wrap condition occurs, the scheduling of the split transaction spans more than one location in the periodic list. (For example, it takes two siTDs in adjacent periodic frame list locations to fully describe the scheduling for the split transaction.)
- Although the scheduling of the split transaction may take two data structures, all of the complete-splits for each full-speed IN isochronous transaction must use only one data pointer. For this reason, siTDs contain a back pointer, the use of which is described below.
- Software must never schedule full-speed isochronous OUTs across an *H-Frame* boundary.
- *Case 2b*: This case can only occur for a very large isochronous IN. It is the only allowed scenario where a start-split and complete-split for the same endpoint can occur in the same micro-frame. Software must enforce this rule by scheduling the large transaction first. Large is defined to be anything larger than 579 byte maximum packet size.

A subset of the same mechanisms employed by full- and low-speed interrupt queue heads are employed in siTDs to schedule and track the portions of isochronous split transactions. The following fields are initialized by system software to instruct the host controller when to execute portions of the split transaction protocol.

- *SplitXState*. This is a single bit residing in the *Status* field of an siTD (see [Figure 11-84](#)). This bit is used to track the current state of the split transaction. The rules for managing this bit are described in [Section Split Transaction Execution State Machine for Interrupt](#).
- *Frame S-mask*. This is a bit-field where-in system software sets a bit corresponding to the micro-frame (within an *H-Frame*) that the host controller should execute a start-split transaction. This is always qualified by the value of the *SplitXState* bit. For example, referring to the IN example in [Figure 11-83](#), case one, the *S-mask* would have a value of 00000001b indicating that if the siTD is traversed by the host controller, and the *SplitXState* indicates Do Start Split, and the current micro-frame as indicated by `USB_n_FRINDEX[2:0]` is 0, then execute a start-split transaction.
- *Frame C-mask*. This is a bit-field where system software sets one or more bits corresponding to the micro-frames (within an *H-Frame*) that the host controller should execute complete-split transactions. The interpretation of this field is always qualified by the value of the *SplitXState* bit. For example, referring to the IN example in [Figure 11-83](#), case one, the *C-mask* would have a value of 00111100b indicating that if the siTD is traversed by the host controller, and the *SplitXState* indicates Do

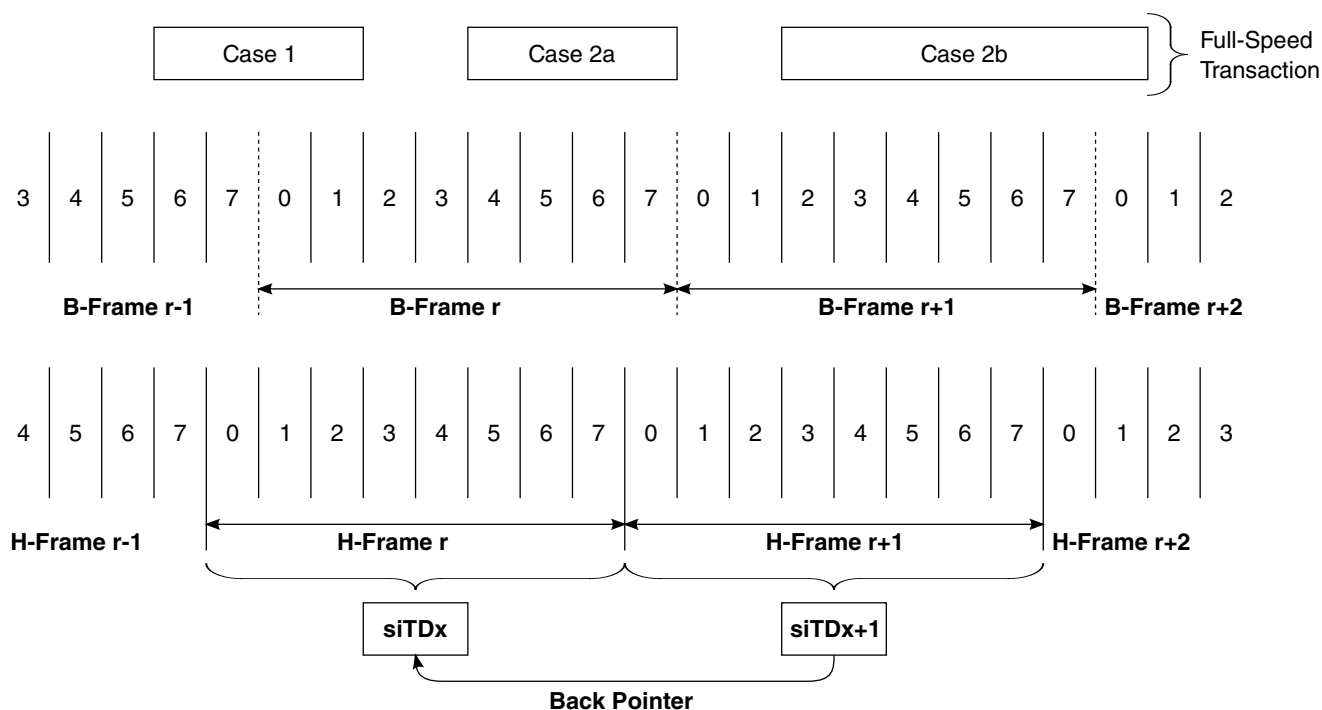

Complete Split, and the current micro-frame as indicated by *USB\_n\_FRINDEX*[2:0] is 2, 3, 4, or 5, then execute a complete-split transaction.

- *Back Pointer*. This field in a siTD is used to complete an IN split-transaction using the previous *H-Frame*'s siTD. This is only used when the scheduling of the complete-splits span an *H-Frame* boundary.

There exists a one-to-one relationship between a high-speed isochronous split transaction (including all start- and complete-splits) and one full-speed isochronous transaction. An siTD contains (amongst other things) buffer state and split transaction scheduling information. An siTD's buffer state always maps to one full-speed isochronous data payload. This means that for any full-speed transaction payload, a single siTD's data buffer must be used. This rule applies to both IN and OUTs. An siTD's scheduling information usually also maps to one high-speed isochronous split transaction. The exception to this rule is the *H-Frame* boundary wrap cases mentioned above.

The siTD data structure describes at most, one frame's worth of high-speed transactions and that description is strictly bounded within a frame boundary. The figure below illustrates some examples. On the top are examples of the full-speed transaction footprints for the boundary scheduling cases described above. In the middle are time-frame references for both the *B-Frames* (HS/FS/LS Bus) and the *H-Frames*. On the bottom is illustrated the relationship between the scope of an siTD description and the time references. Each *H-Frame* corresponds to a single location in the periodic frame list. The implication is that each siTD is reachable from a single periodic frame list location at a time.

**Figure 11-84. siTD Scheduling Boundary Examples**

Each case is described below:

- *Case 1*: One siTD is sufficient to describe and complete the isochronous split transaction because the whole isochronous split transaction is tightly contained within a single *H-Frame*.
- *Case 2a, 2b*: Although both INs and OUTs can have these footprints, OUTs always take only one siTD to schedule. However, INs (for these boundary cases) require two siTDs to complete the scheduling of the isochronous split transaction.  $siTD_X$  is used to always issue the start-split and the first  $N$  complete-splits. The full-speed transaction (for these cases) can deliver data on the full-speed bus segment during micro-frame 7 of *H-Frame* <sub>$Y+1$</sub> , or micro-frame 0 of *H-Frame* <sub>$Y+2$</sub> . The complete splits are scheduled using  $siTD_{X+2}$  (not shown). The complete-splits to extract this data must use the buffer pointer from  $siTD_{X+1}$ . The only way for the host controller to reach  $siTD_{X+1}$  from *H-Frame* <sub>$Y+2$</sub>  is to use  $siTD_{X+2}$ 's back pointer. The host controller rules for when to use the back pointer are described in Section [Periodic Isochronous - Do Complete Split](#).

Software must apply the following rules when calculating the schedule and linking the schedule data structures into the periodic schedule:

- Software must ensure that an isochronous split-transaction is started so that it will complete before the end of the *B-Frame*.
- Software must ensure that for a single full-speed isochronous endpoint, there is never a start-split and complete-split in *H-Frame, micro-frame 1*. This is mandated as a rule so that case 2a and case 2b can be discriminated. According to the core USB specification, the long isochronous transaction illustrated in Case 2b, could be scheduled so that the start-split was in micro-frame 1 of *H-Frame N* and the last complete-split would need to occur in micro-frame 1 of *H-Frame N+1*. However, it is impossible to discriminate between cases 2a and case 2b, which has significant impact on the complexity of the host controller.

#### 11.4.4.3.12.3.2 Tracking Split Transaction Progress for Isochronous Transfers

To correctly maintain the data stream, the host controller must be able to detect and report errors where device to host data is lost. Isochronous endpoints do not employ the concept of a halt on error, however the host is required to identify and report per-packet errors observed in the data stream. This includes schedule traversal problems (skipped micro-frames), timeouts and corrupted data received.

In similar kind to interrupt split-transactions, the portions of the split transaction protocol must execute in the micro-frames they are scheduled. The queue head data structure used to manage full- and low-speed interrupt has several mechanisms for tracking when portions of a transaction have occurred. Isochronous transfers use siTDs, for their transfers, and the data structures are only reachable via the schedule in the exact micro-frame in which they are required (so all the mechanism employed for tracking in queue heads is not required for siTDs). Software has the option of reusing siTD several times in the complete periodic schedule. However, it must ensure that the results of split transaction *N* are consumed and the siTD reinitialized (activated) before the host controller gets back to the siTD (in a future micro-frame).

Split-transaction isochronous OUTs utilize a low-level protocol to indicate which portions of the split transaction data have arrived. Control over the low-level protocol is exposed in an siTD via the fields *Transaction Position (TP)* and *Transaction Count (T-count)*. If the entire data payload for the OUT split transaction is larger than 188 bytes, there will be more than one start-split transaction, each of which require proper annotation. If host hold-offs occur, then the sequence of annotations received from the host will not be complete, which is detected and handled by the transaction translator. See Section [Periodic Isochronous - Do Start Split](#) for a description on how these fields are used during a sequence of start-split transactions.

The fields *siTD.T-Count* and *siTD.TP* are used by the host controller to drive and sequence the transaction position annotations. It is the responsibility of system software to properly initialize these fields in each siTD. Once the budget for a split-transaction

isochronous endpoint is established, *S-mask*, *T-Count*, and *TP* initialization values for all the siTD associated with the endpoint are constant. They remain constant until the budget for the endpoint is recalculated by software and the periodic schedule adjusted.

For IN-endpoints, the transaction translator simply annotates the response data packets with enough information to allow the host controller to identify the last data. As with split transaction Interrupt, it is the host controller's responsibility to detect when it has missed an opportunity to execute a complete-split. The following field in the siTD is used to track and detect errors in the execution of a split transaction for an IN isochronous endpoint.

- *C-prog-mask*. This is an eight-bit bit-vector where the host controller keeps track of which complete-splits have been executed. Due to the nature of the Transaction Translator periodic pipeline, the complete-splits need to be executed in-order. The host controller needs to detect when the complete-splits have not been executed in order. This can only occur due to system hold-offs where the host controller cannot get to the memory-based schedule. *C-prog-mask* is a simple bit-vector that the host controller sets a bit for each complete-split executed. The bit position is determined by the micro-frame (`USB_n_FRINDEX[2:0]`) number in which the complete-split was executed. The host controller always checks *C-prog-mask* before executing a complete-split transaction. If the previous complete-splits have not been executed, then it means one (or more) have been skipped and data has potentially been lost. System software is required to initialize this field to zero before setting an siTD's *Active* bit to a one.

If a transaction translator returns with the final data before all of the complete-splits have been executed, the state of the transfer is advanced so that the remaining complete-splits are not executed. Refer to Section [Asynchronous - Do Complete Split](#) for a description on how the state of the transfer is advanced. It is important to note that an IN siTD is retired based solely on the responses from the Transaction Translator to the complete-split transactions. This means, for example, that it is possible for a transaction translator to respond to a complete-split with an MDATA PID. The number of bytes in the MDATA's data payload could cause the siTD field *Total Bytes to Transfer* to decrement to zero. This response can occur, before all of the scheduled complete-splits have been executed. In other interface, data structures (for example, high-speed data streams through queue heads), the transition of *Total Bytes to Transfer* to zero signals the end of the transfer and results in setting of the *Active* bit to zero. However, in this case, the result has not been delivered by the Transaction Translator and the host must continue with the next complete-split transaction to extract the residual transaction state. This scenario occurs because of the pipeline rules for a Transaction Translator (see Chapter 11 of the Universal Serial Bus Revision 2.0). In summary the periodic pipeline rules require that on a micro-frame boundary, the Transaction Translator will hold the final two bytes received (if it has not seen an End Of Packet (EOP)) in the full-speed bus pipe stage and give the

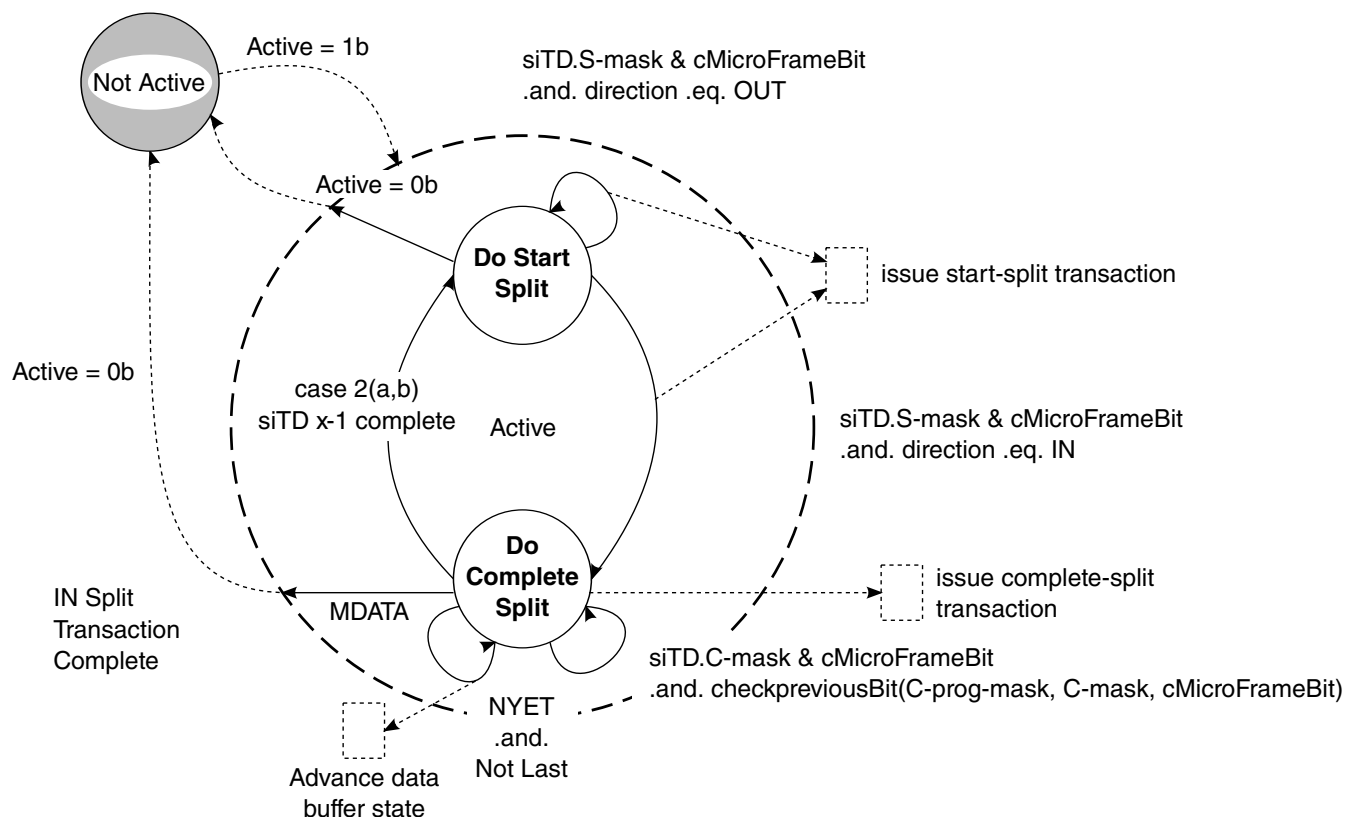

remaining bytes to the high-speed pipeline stage. At the micro-frame boundary, the Transaction Translator could have received the entire packet (including both CRC bytes) but not received the packet EOP. In the next micro-frame, the Transaction Translator will respond with an MDATA and send all of the data bytes (with the two CRC bytes being held in the full-speed pipeline stage). This could cause the siTD to decrement its *Total Bytes to Transfer* field to zero, indicating it has received all expected data. The host must still execute one more (scheduled) complete-split transaction in order to extract the results of the full-speed transaction from the Transaction Translator (for example, the Transaction Translator may have detected a CRC failure, and this result must be forwarded to the host).

If the host experiences hold-offs that cause the host controller to skip one or more (but not all) scheduled split transactions for an isochronous OUT, then the protocol to the transaction translator will not be consistent and the transaction translator will detect and react to the problem. Likewise, for host hold-offs that cause the host controller to skip one or more (but not all) scheduled split transactions for an isochronous IN, the *C-prog-mask* is used by the host controller to detect errors. However, if the host experiences a hold-off that causes it to skip all of an siTD, or an siTD expires during a host hold off (for example, a hold-off occurs and the siTD is no longer reachable by the host controller in order for it to report the hold-off event), then system software must detect that the siTDs have not been processed by the host controller (that is, state not advanced) and report the appropriate error to the client driver.

#### 11.4.4.3.12.3.3 Split Transaction Execution State Machine for Isochronous

In the following presentation, all references to micro-frame are in the context of a micro-frame within an *H-Frame*.

If the *Active* bit in the *Status* byte is a zero, the host controller will ignore the siTD and continue traversing the periodic schedule. Otherwise the host controller will process the siTD as specified below. A split transaction state machine is used to manage the split-transaction protocol sequence. The host controller uses the fields defined in Section [Tracking Split Transaction Progress for Interrupt Transfers](#), plus the variable *cMicroFrameBit* defined in Section [Split Transaction Execution State Machine for Interrupt](#) to track the progress of an isochronous split transaction. The figure below illustrates the state machine for managing an siTD through an isochronous split transaction. Bold, dotted circles denote the state of the *Active* bit in the *Status* field of a siTD. The Bold, dotted arcs denote the transitions between these states. Solid circles denote the states of the split transaction state machine and the solid arcs denote the transitions between these states. Dotted arcs and boxes reference actions that take place either as a result of a transition or from being in a state.

**Figure 11-85. Split Transaction State Machine for Isochronous**

#### 11.4.4.3.12.3.4 Periodic Isochronous - Do Start Split

Isochronous split transaction OUTs use only this state.

An *siTD* for a split-transaction isochronous IN is either initialized to this state, or the *siTD* transitions to this state from **Do Complete Split** when a case 2a (IN) or 2b scheduling boundary isochronous split-transaction completes.

Each time the host controller reaches an active *siTD* in this state, it checks the *siTD.S-mask* against *cMicroFrameBit*. If there is a one in the appropriate position, the *siTD* will execute a start-split transaction. By definition, the host controller cannot *reach* an *siTD* at the wrong time. If the *I/O* field indicates an IN, then the start-split transaction includes only the extended token plus the full-speed token. Software must initialize the *siTD.Total Bytes To Transfer* field to the number of bytes expected. This is usually the maximum packet size for the full-speed endpoint. The host controller exits this state when the start-split transaction is complete.

The remainder of this section is specific to an isochronous OUT endpoint (that is, the *I/O* field indicates an OUT). When the host controller executes a start-split transaction for an isochronous OUT it includes a data payload in the start-split transaction. The memory

buffer address for the data payload is constructed by concatenating *siTD.Current Offset* with the page pointer indicated by the page selector field (*siTD.P*). A zero in this field selects Page 0 and a 1 selects Page 1. During the start-split for an OUT, if the data transfer crosses a page boundary during the transaction, the host controller must detect the page cross, update the *siTD.P*-bit from a zero to a one, and begin using the *siTD.Page 1* with *siTD.Current Offset* as the memory address pointer. The field *siTD.TP* is used to annotate each start-split transaction with the indication of which part of the split-transaction data the current payload represents (ALL, BEGIN, MID, END). In all cases the host controller simply uses the value in *siTD.TP* to mark the start-split with the correct transaction position code.

*T-Count* is always initialized to the number of start-splits for the current frame. *TP* is always initialized to the first required transaction position identifier. The scheduling boundary case (see [Figure 11-84](#)) is used to determine the initial value of *TP*. The initial cases are summarized in the following table.

**Table 11-104. Initial Conditions for OUT siTD's TP and T-count Fields**

Case	T-count	TP	Description
1, 2a	=1	ALL	When the OUT data payload is less than (or equal to) 188 bytes, only one start-split is required to move the data. The one start-split must be marked with an ALL.
1, 2a	!=1	BEGIN	When the OUT data payload is greater than 188 bytes more than one start-split must be used to move the data. The initial start-split must be marked with a BEGIN.

After each start-split transaction is complete, the host controller updates *T-Count* and *TP* appropriately so that the next start-split is correctly annotated.

The table below illustrates all of the *TP* and *T-count* transitions, which must be accomplished by the host controller.

**Table 11-105. Transaction Position (TP)/Transaction Count (T-Count) Transition Table**

TP	T-count next	TP next	Description
ALL	0	N/A	Transition from ALL, to done.
BEGIN	1	END	Transition from BEGIN to END. Occurs when <i>T-count</i> starts at 2.
BEGIN	!=1	MID	Transition from BEGIN to MID. Occurs when <i>T-count</i> starts at greater than 2.
MID	!=1	MID	<i>TP</i> stays at MID while <i>T-count</i> is not equal to 1 (that is, greater than 1). This case can occur for any of the scheduling boundary cases where the <i>T-count</i> starts greater than 3.
MID	1	END	Transition from MID to END. This case can occur for any of the scheduling boundary cases where the <i>T-count</i> starts greater than 2.

The start-split transactions do not receive a handshake from the transaction translator, so the host controller always advances the transfer state in the siTD after the bus transaction is complete. To advance the transfer state the following operations take place:

- The *siTD.Total Bytes To Transfer* and the *siTD.Current Offset* fields are adjusted to reflect the number of bytes transferred.
- The *siTD.P* (page selector) bit is updated appropriately.
- The *siTD.TP* and *siTD.T-count* fields are updated appropriately as defined in [Table 11-105](#).

These fields are then written back to the memory based siTD. The *S-mask* is fixed for the life of the current budget. As mentioned above, *TP* and *T-count* are set specifically in each siTD to reflect the data to be sent from this siTD. Therefore, regardless of the value of *S-mask*, the actual number of start-split transactions depends on *T-count* (or equivalently, *Total Bytes to Transfer*). The host controller must set the *Active* bit to a zero when it detects that all of the schedule data has been sent to the bus. The preferred method is to detect when *T-Count* decrements to zero as a result of a start-split bus transaction. Equivalently, the host controller can detect when *Total Bytes to Transfer* decrements to zero. Either implementation must ensure that if the initial condition is *Total Bytes to Transfer* equal to zero and *T-count* is equal to a one, then the host controller will issue a single start-split, with a zero-length data payload. Software must ensure that *TP*, *T-count* and *Total Bytes to Transfer* are set to deliver the appropriate number of bus transactions from each siTD. An inconsistent combination will yield undefined behavior.

If the host experiences hold-offs that cause the host controller to skip start-split transactions for an OUT transfer, the state of the transfer will not progress appropriately. The transaction translator will observe protocol violations in the arrival of the start-splits for the OUT endpoint (that is, the transaction position annotation will be incorrect as received by the transaction translator).

Example scenarios are described in [Section Split Transaction for Isochronous - Processing Examples](#).

A host controller implementation can optionally track the progress of an OUT split transaction by setting appropriate bits in the *siTD.C-prog-mask* as it executes each scheduled start-split. The *checkPreviousBit()* algorithm defined in [Periodic Isochronous - Do Complete Split](#) can be used prior to executing each start-split to determine whether start-splits were skipped. The host controller can use this mechanism to detect missed micro-frames. It can then set the siTD's *Active* bit to zero and stop execution of this siTD. This saves on both memory and high-speed bus bandwidth.

## 11.4.4.3.12.3.5 Periodic Isochronous - Do Complete Split

This state is only used by a split-transaction isochronous IN endpoint.

This state is entered unconditionally from the Do Start State after a start-split transaction is executed for an IN endpoint. Each time the host controller visits an siTD in this state, it conducts a number of tests to determine whether it should execute a complete-split transaction. The individual tests are listed below. The sequence they are applied depends on which micro-frame the host controller is currently executing which means that the tests might not be applied until after the siTD referenced from the back pointer has been fetched.

- Test A. *cMicroFrameBit* is bit-wise anded with *siTD.C-mask* field. A non-zero result indicates that software scheduled a complete-split for this endpoint, during this micro-frame. This test is always applied to a newly fetched siTD that is in this state.
- Test B. The *siTD.C-prog-mask* bit vector is checked to determine whether the previous complete splits have been executed. An example algorithm is below (this is slightly different than the algorithm used in Section [Periodic Isochronous - Do Complete Split](#)). The sequence in which this test is applied depends on the current value of `USB_n_FRINDEX[2:0]`. If `USB_n_FRINDEX[2:0]` is 0 or 1, it is not applied until the back pointer has been used. Otherwise it is applied immediately.

Algorithm Boolean CheckPreviousBit(*siTD.C-prog-mask*, *siTD.C-mask*, *cMicroFrameBit*)

Begin

```

Boolean rvalue = TRUE;
previousBit = cMicroFrameBit rotate-right(1)
-- Bit-wise anding previousBit with C-mask indicates whether there was an intent
-- to send a complete split in the previous micro-frame. So, if the
-- 'previous bit' is set in C-mask, check C-prog-mask to make sure it
-- happened.
if previousBit bitAND siTD.C-mask then
    if not (previousBit bitAND siTD.C-prog-mask) then
        rvalue = FALSE
    End if
End if
Return rvalue

```

End Algorithm

If Test A is true and `USB_n_FRINDEX[2:0]` is zero or one, then this is a case 2a or 2b scheduling boundary (see [Figure 11-83](#)). See Section [Periodic Isochronous - Do Complete Split](#) for details in handling this condition.

If Test A and Test B evaluate to true, then the host controller will execute a complete-split transaction using the transfer state of the current siTD. When the host controller commits to executing the complete-split transaction, it updates *QH.C-prog-mask* by bit-ORing with *cMicroFrameBit*. The transfer state is advanced based on the completion status of the complete-split transaction. To advance the transfer state of an IN siTD, the host controller must:

- Decrement the number of bytes received from *siTD.Total Bytes To Transfer*,
- Adjust *siTD.Current Offset* by the number of bytes received,

- Adjust *siTD.P* (page selector) field if the transfer caused the host controller to use the next page pointer, and
- Set any appropriate bits in the *siTD.Status* field, depending on the results of the transaction.

Note that if the host controller encounters a condition where *siTD.Total Bytes To Transfer* is zero, and it receives more data, the host controller must not write the additional data to memory. The *siTD.Status.Active* bit must be set to zero and the *siTD.Status.Babble Detected* bit must be set to a one. The fields *siTD.Total Bytes To Transfer*, *siTD.Current Offset*, and *siTD.P* (page selector) are not required to be updated as a result of this transaction attempt.

The host controller must accept (assuming good data packet CRC and sufficient room in the buffer as indicated by the value of *siTD.Total Bytes To Transfer*) MDATA and DATA0/1 data payloads up to and including 192 bytes. A host controller implementation may optionally set *siTD.Status Active* to a zero and *siTD.Status.Babble Detected* to a one when it receives and MDATA or DATA0/1 with a data payload of more than 192 bytes. The following responses have the noted effects:

- ERR. The full-speed transaction completed with a time-out or bad CRC and this is a reflection of that error to the host. The host controller sets the *ERR* bit in the *siTD.Status* field and sets the *Active* bit to a zero.
- Transaction Error (XactErr). The complete-split transaction encounters a Timeout, CRC16 failure, etc. The *siTD.Status* field *XactErr* field is set to a one and the complete-split transaction must be retried immediately. The host controller must use an internal error counter to count the number of retries as a counter field is not provided in the siTD data structure. The host controller will not retry more than two times. If the host controller exhausts the retries or the end of the micro-frame occurs, the *Active* bit is set to zero.
- DATAx (0 or 1). This response signals that the final data for the split transaction has arrived. The transfer state of the siTD is advanced and the *Active* bit is set to a zero. If the *Bytes To Transfer* field has not decremented to zero (including the reception of the data payload in the DATAx response), then less data than was expected, or allowed for was actually received. This *short packet* event does not set the USBINT status bit in the USBSTS register to a one. The host controller will not detect this condition.
- NYET (and Last). On each NYET response, the host controller also checks to determine whether this is the last complete-split for this split transaction. Last was defined in Section [Periodic Isochronous - Do Complete Split](#) . If it is the last complete-split (with a NYET response), then the transfer state of the siTD is not advanced (never received any data) and the *Active* bit is set to a zero. No bits are set in the *Status* field because this is essentially a skipped transaction. The transaction translator must have responded to all the scheduled complete-splits with NYETs,

meaning that the start-split issued by the host controller was not received. This result should be interpreted by system software as if the transaction was completely skipped. The test for whether this is the last complete split can be performed by XORing C-mask with C-prog-mask. A zero result indicates that all complete-splits have been executed.

- MDATA (and Last). See above description for testing for Last. This can only occur when there is an error condition. Either there has been a babble condition on the full-speed link, which delayed the completion of the full-speed transaction, or software set up the *S-mask* and/or *C-masks* incorrectly. The host controller must set *XactErr* bit to a one and the *Active* bit is set to a zero.
- NYET (and not Last). See above description for testing for Last. The complete-split transaction received a NYET response from the transaction translator. Do not update any transfer state (except for *C-prog-mask*) and stay in this state.
- MDATA (and not Last). The transaction translator responds with an MDATA when it has partial data for the split transaction. For example, the full-speed transaction data payload spans from micro-frame X to X+1 and during micro-frame X, the transaction translator will respond with an MDATA and the data accumulated up to the end of micro-frame X. The host controller advances the transfer state to reflect the number of bytes received.

If Test A succeeds, but Test B fails, it means that one or more of the complete-splits have been skipped. The host controller sets the *Missed Micro-Frame* status bit and sets the *Active* bit to a zero.

11.4.4.3.12.3.6 Complete-Split for Scheduling Boundary Cases 2a, 2b

Boundary cases 2a and 2b (INs only) (see [Figure 11-83](#)) require that the host controller use the transaction state context of the previous siTD to finish the split transaction. The table below enumerates the transaction state fields.

**Table 11-106. Summary siTD Split Transaction State**

Buffer State	Status	Execution Progress
Total Bytes To Transfer	All bits in the status field	C-prog-mask
P (page select)		
Current Offset		
TP (transaction position)		
T-count (transaction count)		

**NOTE**

*TP* and *T-count* are used only for Host to Device (OUT) endpoints.

If software has budgeted the schedule of this data stream with a frame wrap case, then it must initialize the *siTD.Back Pointer* field to reference a valid siTD and will have the *siTD.Back Pointer.T-bit* in the *siTD.Back Pointer*

field set to a zero. Otherwise, software must set the *siTD.Back Pointer.T-bit* in the *siTD.Back Pointer* field to a one. The host controller's rules for interpreting when to use the *siTD.Back Pointer* field are listed below. These rules apply only when the siTD's *Active* bit is a one and the *SplitXState* is Do Complete Split.

- When *cMicroFrameBit* is a 1h and the *siTDX.Back Pointer.T-bit* is a zero, or
- If *cMicroFrameBit* is a 2h and *siTDX.S-mask[0]* is a zero

When either of these conditions apply, then the host controller must use the transaction state from *siTD<sub>X-1</sub>*.

In order to access *siTD<sub>X-1</sub>*, the host controller reads on-chip the siTD referenced from *siTD<sub>X</sub>.Back Pointer*.

The host controller must save the entire state from *siTD<sub>X</sub>* while processing *siTD<sub>X-1</sub>*. This is to accommodate for case 2b processing. The host controller must not recursively walk the list of *siTD.Back Pointers*.

If *siTD<sub>X-1</sub>* is active (*Active* bit is a one and *SplitXStat* is Do Complete Split), then both Test A and Test B are applied as described above. If these criteria to execute a complete-split are met, the host controller executes the complete split and evaluates the results as described above. The transaction state (see [Table 11-106](#)) of *siTD<sub>X-1</sub>* is appropriately advanced based on the results and written back to memory. If the resultant state of *siTD<sub>X-1</sub>*'s *Active* bit is a one, then the host controller returns to the context of *siTD<sub>X</sub>*, and follows its next pointer to the next schedule item. No updates to *siTD<sub>X</sub>* are necessary.

If *siTD<sub>X-1</sub>* is active (*Active* bit is a one and *SplitXStat* is Do Start Split), then the host controller must set *Active* bit to a zero and *Missed Micro-Frame* status bit to a one and the resultant status written back to memory.

If *siTD<sub>X-1</sub>*'s *Active* bit is a zero, (because it was zero when the host controller first visited *siTD<sub>X-1</sub>* via *siTD<sub>X</sub>*'s back pointer, it transitioned to zero as a result of a detected error, or the results of *siTD<sub>X-1</sub>*'s complete-split transaction transitioned it to zero), then the host controller returns to the context of *siTD<sub>X</sub>* and transitions its *SplitXState* to Do Start Split. The host controller then determines whether the case 2b start split boundary condition exists (that is, if *cMicroframeBit* is a 1b and *siTD<sub>X</sub>.S-mask[0]* is a 1b). If this criterion is met the host controller immediately executes a start-split transaction and appropriately advances the transaction state of *siTD<sub>X</sub>*, then follows *siTD<sub>X</sub>.Next Pointer* to the next schedule item. If the criterion is not met, the host controller simply follows *siTD<sub>X</sub>.Next Pointer* to the next schedule item. Note that in the case of a 2b boundary case, the split-transaction of *siTD<sub>X-1</sub>* will have its *Active* bit set to zero when the host controller returns

to the context of  $siTD_x$ . Also, note that software should not initialize an siTD with *C-mask* bits 0 and 1 set to a one and an *S-mask* with bit zero set to a one. This scheduling combination is not supported and the behavior of the host controller is undefined.

11.4.4.3.12.3.7 Split Transaction for Isochronous - Processing Examples

There is an important difference between how the hardware/software manages the isochronous split transaction state machine and how it manages the asynchronous and interrupt split transaction state machines.

The asynchronous and interrupt split transaction state machines are encapsulated within a single queue head. The progress of the data stream depends on the progress of each split transaction. In some respects, the split-transaction state machine is sequenced via the Execute Transaction queue head traversal state machine (see [Figure 11-76](#)).

Isochronous is a pure time-oriented transaction/data stream. The interface data structures are optimized to efficiently describe transactions that need to occur at specific times. The isochronous split-transaction state machine must be managed across these time-oriented data structures. This means that system software must correctly describe the scheduling of split-transactions across more than one data structure.

Then the host controller must make the appropriate state transitions at the appropriate times, in the correct data structures.

For example, the table below illustrates a couple of frames worth of scheduling required to schedule a case 2a full-speed isochronous data stream.

**Table 11-107. Example Case 2a - Software Scheduling siTDs for an IN Endpoint**

siTDx		Micro-Frames								Initial
#	Masks	0	1	2	3	4	5	6	7	SplitXState
X	S-Mask	-	-	-	-	1	-	-	-	Do Start Split
	C-Mask	1	1	-	-	-	-	1	1	
X+1	S-Mask	-	-	-	-	1	-	-	-	Do Complete Split
	C-Mask	1	1					1	1	
X+2	S-Mask	-	-	-	-	1	-	-	-	Do Complete Split
	C-Mask	1	1					1	1	
X+3	S-Mask	Repeats previous pattern								Do Complete Split
	C-Mask									

This example shows the first three siTDs for the transaction stream. Because this is the case-2a frame-wrap case, *S-masks* of all siTDs for this endpoint have a value of 10h (a one bit in micro-frame 4) and *C-mask* value of C3h (one-bits in micro-frames 0,1, 6 and 7). Additionally, software ensures that the *Back Pointer* field of each siTD references the appropriate siTD data structure (and the *Back PointerT-bits* are set to zero).

The initial *SplitXState* of the first siTD is Do Start Split. The host controller will visit the first siTD eight times during frame X. The C-mask bits in micro-frames 0 and 1 are ignored because the state is Do Start Split. During micro-frame 4, the host controller determines that it can run a start-split (and does) and changes *SplitXState* to Do Complete Split. During micro-frames 6 and 7, the host controller executes complete-splits. Notice the siTD for frame X+1 has its *SplitXState* initialized to Do Complete Split. As the host controller continues to traverse the schedule during *H-Frame* X+1, it will visit the second siTD eight times. During micro-frames 0 and 1 it will detect that it must execute complete-splits.

During *H-Frame* X+1, micro-frame 0, the host controller detects that siTD<sub>X+1</sub>'s *Back Pointer.T-bit* is a zero, saves the state of siTD<sub>X+1</sub> and fetches siTD<sub>X</sub>. It executes the complete split transaction using the transaction state of siTD<sub>X</sub>. If the siTD<sub>X</sub> split transaction is complete, siTD's *Active* bit is set to zero and results written back to siTD<sub>X</sub>. The host controller retains the fact that siTD<sub>X</sub> is retired and transitions the *SplitXState* in the siTD<sub>X+1</sub> to Do Start Split. At this point, the host controller is prepared to execute the start-split for siTD<sub>X+1</sub> when it reaches micro-frame 4. If the split-transaction completes early (transaction-complete is defined in Section [Periodic Isochronous - Do Complete Split](#)), that is, before all the scheduled complete-splits have been executed, the host controller will transition *siTD<sub>X</sub>.SplitXState* to Do Start Split early and naturally skip the remaining scheduled complete-split transactions. For this example, siTD<sub>X+1</sub> does not receive a DATA0 response until *H-Frame* X+2, micro-frame 1.

During *H-Frame* X+2, micro-frame 0, the host controller detects that siTD<sub>X+2</sub>'s *Back Pointer.T-bit* is a zero, saves the state of siTD<sub>X+2</sub> and fetches siTD<sub>X+1</sub>. As described above, it executes another split transaction, receives an MDATA response, updates the transfer state, but does not modify the *Active* bit. The host controller returns to the context of siTD<sub>X+2</sub>, and traverses its next pointer without any state change updates to siTD<sub>X+2</sub>. S

During *H-Frame* X+2, micro-frame 1, the host controller detects siTD<sub>X+2</sub>'s *S-mask[0]* is a zero, saves the state of siTD<sub>X+2</sub> and fetches siTD<sub>X+1</sub>. It executes another complete-split transaction, receives a DATA0 response, updates the transfer state and sets the *Active* bit to a zero. It returns to the state of siTD<sub>X+2</sub> and changes its *SplitXState* to Do Start Split. At this point, the host controller is prepared to execute start-splits for siTD<sub>X+2</sub> when it

reaches micro-frame 4. <TBD... describe how software detects that there was missing micro-frames (don't think we care about missing out micro-frames. There is enough residual state to identify than not all transactions were executed.).

#### 11.4.4.3.13 Host Controller Pause

When the host controller's *HCHalted* bit in the USBSTS register is a zero, the host controller is sending SOF (Start OF Frame) packets down all enabled ports.

When the schedules are enabled, the EHCI host controller will access the schedules in main memory each micro-frame. This constant pinging of main memory is known to create ARM platform power management problems for mobile systems. Specifically, mobile systems aggressively manage the state of the ARM platform, based on recent history usage. In the more aggressive power saving modes, the ARM platform can disable its caches. Current PC architectures assume that bus-master accesses to main memory must be cache-coherent. So, when bus masters are busy touching memory, the ARM platform power management software can detect this activity over time and inhibit the transition of the ARM platform into its lowest power savings mode. USB controllers are bus-masters and the frequency at which they access their memory-based schedules keeps the ARM platform power management software from placing the ARM platform into its lowest power savings state.

USB Host controllers don't access main memory when they are suspended. However, there are a variety of reasons why placing the USB controllers into suspend won't work, but they are beyond the scope of this document. The base requirement is that the USB controller needs to be kept out of main memory, while at the same time, the USB bus is kept from going into suspend.

EHCI controllers provide a large-grained mechanism that can be manipulated by system software to change the memory access pattern of the host controller. System software can manipulate the schedule enable bits in the USBCMD register to turn on/off the scheduling traversal. A software heuristic can be applied to implement an on/off duty cycle that allows the USB to make reasonable progress and allow the ARM platform power management to get the ARM platform into its lowest power state. This method is not intended to be applied at all times to throttle USB, but should only be applied in very specific configurations and usage loads. For example, when only a keyboard or mouse is attached to the USB, the heuristic could detect times when the USB is attempting to move data only very infrequently and can adjust the duty cycle to allow the ARM platform to reach its low power state for longer periods of time. Similarly, it could detect increases in the USB load and adjust the duty cycle appropriately, even to the point where the schedules are never disabled. The assumption here is that the USB is moving data and the ARM platform will be required to process the data streams.

It is suggested that in order to provide a complete solution for the system, the companion host controllers should also provide a similar method to allow system software to inhibit the companion host controller from accessing its shared memory based data structures (schedule lists or otherwise).

#### 11.4.4.3.14 Port Test Modes -Host Operational Model

EHCI host controllers must implement the port test modes Test J\_State, Test K\_State, Test\_Packet, Test Force\_Enable, and Test SEO\_NAK as described in the USB Specification Revision 2.0.

The system is only allowed to test ports that are owned by the EHCI controller (for example, *CF-bit* is a one and *PortOwner* bit is a zero). System software is allowed to have at most one port in test mode at a time. Placing more than one port in test mode will yield undefined results. The required, per port test sequence is (assuming the *CF-bit* in the USB\_n\_CONFIGFLAG register is a one):

- Disable the periodic and asynchronous schedules by setting the *Asynchronous Schedule Enable* and *Periodic Schedule Enable* bits in the USBCMD register to a zero.
- Place all enabled root ports into the suspended state by setting the *Suspend* bit in each appropriate USB\_n\_PORTSC register to a one.
- Set the *Run/Stop* bit in the USBCMD register to a zero and wait for the *HCHalted* bit in the USBSTS register, to transition to a one. Note that an EHCI host controller implementation may optionally allow port testing with the *Run/Stop* bit set to a one. However, all host controllers must support port testing with *Run/Stop* set to a zero and *HCHalted* set to a one.
- Set the *Port Test Control* field in the port under test PORTSC register to the value corresponding to the desired test mode. If the selected test is Test\_Force\_Enable, then the *Run/Stop* bit in the USBCMD register must then be transitioned back to one, in order to enable transmission of SOFs out of the port under test.
- When the test is complete, system software must ensure the host controller is halted (*HCHalted* bit is a one) then it terminates and exits test mode by setting *HCRreset* to a one.

#### 11.4.4.3.15 Interrupts-Host Operational Model

The EHCI Host Controller hardware provides interrupt capability based on a number of sources.

There are several general groups of interrupt sources:

- Interrupts as a result of executing transactions from the schedule (success and error conditions),
- Host controller events (Port change events, etc.), and
- Host Controller error events

All transaction-based sources are maskable through the Host Controller's Interrupt Enable register (USBINTR, see Section ). Additionally, individual transfer descriptors can be marked to generate an interrupt on completion. This section describes each interrupt source and the processing that occurs in response to the interrupt.

During normal operation, interrupts may be immediate or deferred until the next interrupt threshold occurs. The interrupt threshold is a tunable parameter via the *Interrupt Threshold Control* field in the USBCMD register. The value of this register controls when the host controller will generate an interrupt on behalf of normal transaction execution. When a transaction completes during an interrupt interval period, the interrupt signaling the completion of the transfer will not occur until the interrupt threshold occurs. For example, the default value is eight micro-frames. This means that the host controller will not generate interrupts any more frequently than once every eight micro-frames.

Section [Host System Error](#) details effects of a host system error.

If an interrupt has been scheduled to be generated for the current interrupt threshold interval, the interrupt is not signaled until after the status for the last complete transaction in the interval has been written back to host memory. This may sometimes result in the interrupt not being signaled until the next interrupt threshold.

Initial interrupt processing is the same, regardless of the reason for the interrupt. When an interrupt is signaled by the hardware, ARM platform control is transferred to host controller's USB interrupt handler. The precise mechanism to accomplish the transfer is OS specific. For this discussion it is just assumed that control is received. When the interrupt handler receives control, its first action is to read the USBSTS (USB Status Register). It then acknowledges the interrupt by clearing all of the interrupt status bits by writing ones to these bit positions. The handler then determines whether the interrupt is due to schedule processing or some other event. After acknowledging the interrupt, the handler (via an OS-specific mechanism), schedules a deferred procedure call (DPC) which will execute later. The DPC routine processes the results of the schedule execution. The precise mechanisms used are beyond the scope of this document.

Note: the host controller is not required to de-assert a currently active interrupt condition when software sets the interrupt enables (in the USBINTR register, see Section ) to a zero. The only reliable method software should use for acknowledging an interrupt is by transitioning the appropriate status bits in the USBSTS register (Section ) from a one to a zero.

### 11.4.4.3.15.1 Transfer/Transaction Based Interrupts

These interrupt sources are associated with transfer and transaction progress. They are all dependent on the next interrupt threshold.

#### 11.4.4.3.15.1.1 Transaction Error

A transaction error is any error that caused the host controller to think that the transfer did not complete successfully.

The table below lists the events/responses that the host can observe as a result of a transaction. The effects of the error counter and interrupt status are summarized in the following paragraphs. Most of these errors set the *XactErr* status bit in the appropriate interface data structure.

There is a small set of protocol errors that relate only when executing a queue head and fit under the umbrella of a WRONG PID error that are significant to explicitly identify. When these errors occur, the *XactErr* status bit in the queue head is set and the *CErr* field is decremented. When the *PIDCode* indicates a SETUP, the following responses are protocol errors and result in *XactErr* bit being set to a one and the *CErr* field being decremented.

- *EPS* field indicates a high-speed device and it returns a Nak handshake to a SETUP.
- *EPS* field indicates a high-speed device and it returns a Nyet handshake to a SETUP.
- *EPS* field indicates a low- or full-speed device and the complete-split receives a Nak handshake.

**Table 11-108. Summary of Transaction Errors**

Event / Result	Queue Head/qTD/iTD/siTD Side-effects		USB Status Register (USBSTS)
	Cerr	Status Field	USBERRINT
CRC	-1	XactErr set to a one.	1 <sup>1</sup>
Timeout	-1	XactErr set to a one.	1 <sup>1</sup>
Bad PID <sup>2</sup>	-1	XactErr set to a one.	1 <sup>1</sup>
Babble	N/A	Section <a href="#">Serial Bus Babble</a>	1
Buffer Error	N/A	Section <a href="#">Data Buffer Error</a>	

1. If occurs in a queue head, then *USBERRINT* is asserted only when *CErr* counts down from a one to a zero. In addition the queue is halted, see [Halting a Queue Head](#).
2. The host controller received a response from the device, but it could not recognize the PID as a valid PID.

## 11.4.4.3.15.1.2 Serial Bus Babble

When a device transmits more data on the USB than the host controller is expecting for this transaction, it is defined to be babbling. In general, this is called a *Packet Babble*.

When a device sends more data than the *Maximum Length* number of bytes, the host controller sets the *Babble Detected* bit to a one and halts the endpoint if it is using a queue head (see [Halting a Queue Head](#)). *Maximum Length* is defined as the minimum of *Total Bytes to Transfer* and *Maximum Packet Size*. The *CErr* field is not decremented for a packet babble condition (only applies to queue heads). A babble condition also exists if IN transaction is in progress at High-speed EOF2 point. This is called a frame babble. A frame babble condition is recorded into the appropriate schedule data structure. In addition, the host controller must disable the port to which the frame babble is detected.

The *USBERRINT* bit in the *USB\_n\_USBSTS* register is set to a one and if the *USB Error Interrupt Enable* bit in the *USB\_n\_USBINTR* register is a one, then a hardware interrupt is signaled to the system at the next interrupt threshold. The host controller must never start an OUT transaction that will babble across a micro-frame EOF.

**NOTE**

When a host controller detects a data PID mismatch, it must either: disable the packet babble checking for the duration of the bus transaction or do packet babble checking based solely on *Maximum Packet Size*. The USB core specification defines the requirements on a data receiver when it receives a data PID mismatch (for example, expects a DATA0 and gets a DATA1 or visa-versa). In summary, it must ignore the received data and respond with an ACK handshake, in order to advance the transmitter's data sequence.

The EHCI interface allows System software to provide buffers for a Control, Bulk or Interrupt IN endpoint that are not an even multiple of the maximum packet size specified by the device. Whenever a device misses an ACK for an IN endpoint, the host and device are out of synchronization with respect to the progress of the data transfer. The host controller may have advanced the transfer to a buffer that is less than maximum packet size. The device will re-send its maximum packet size data packet, with the original data PID, in response to the next IN token. In order to properly manage the bus protocol, the host controller must disable the packet babble check when it observes the data PID mismatch.

#### 11.4.4.3.15.1.3 Data Buffer Error

This event indicates that an overrun of incoming data or a underrun of outgoing data has occurred for this transaction.

This would generally be caused by the host controller not being able to access required data buffers in memory within necessary latency requirements. These conditions are not considered transaction errors, and do not effect the error count in the queue head. When these errors do occur, the host controller records the fact the error occurred by setting the *Data Buffer Error* bit in the queue head, iTD or siTD.

If the data buffer error occurs on a non-isochronous IN, the host controller will not issue a handshake to the endpoint. This will force the endpoint to resend the same data (and data toggle) in response to the next IN to the endpoint.

If the data buffer error occurs on an OUT, the host controller must corrupt the end of the packet so that it cannot be interpreted by the device as a good data packet. Simply truncating the packet is not considered acceptable. An acceptable implementation option is to 1's complement the CRC bytes and send them. There are other options suggested in the Transaction Translator section of the USB Specification Revision 2.0.

#### 11.4.4.3.15.1.4 USB Interrupt (Interrupt on Completion (IOC))

Transfer Descriptors (iTDS, siTDS, and queue heads (qTDS)) contain a bit that can be set to cause an interrupt on their completion. The completion of the transfer associated with that schedule item causes the USB Interrupt (USBINT) bit in the USB\_n\_USBSTS register to be set to a one.

In addition, if a short packet is encountered on an IN transaction associated with a queue head, then this event also causes USBINT to be set to a one. If the USB Interrupt Enable bit in the USB\_n\_USBINTR register is set to a one, a hardware interrupt is signaled to the system at the next interrupt threshold. If the completion is because of errors, the *USBERRINT* bit in the USB\_n\_USBSTS register is also set to a one.

#### 11.4.4.3.15.1.5 Short Packet

Reception of a data packet that is less than the endpoint's Max Packet size during Control, Bulk or Interrupt transfers signals the completion of the transfer. Whenever a short packet completion occurs during a queue head execution, the *USBINT* bit in the USB\_n\_USBSTS register is set to a one.

If the *USB Interrupt Enable* bit is set in the USB\_n\_USBINTR register, a hardware interrupt is signaled to the system at the next interrupt threshold.

### 11.4.4.3.15.2 Host Controller Event Interrupts

These interrupt sources are independent of the interrupt threshold (with the one exception being the Interrupt on Async Advance, see Section [Interrupt on Async Advance](#) ).

#### 11.4.4.3.15.2.1 Port Change Events

Port registers contain status and status change bits. When the status change bits are set to a one, the host controller sets the *Port Change Detect* bit in the USBSTS register to a one.

If the *Port Change Interrupt Enable* bit in the USB\_n\_USBINTR register is a one, then the host controller will issue a hardware interrupt. The port status change bits include:

- Connect Status Change
- Port Enable/Disable Change
- Over-current Change
- Force Port Resume

#### 11.4.4.3.15.2.2 Frame List Rollover

This event indicates that the host controller has wrapped the frame list. The current programmed size of the frame list effects how often this interrupt occurs.

If the frame list size is 1024, then the interrupt will occur every 1024 milliseconds, if it is 512, then it will occur every 512 milliseconds, etc. When a frame list rollover is detected, the host controller sets the *Frame List Rollover* bit in the USB.USBSTS register to a one. If the *Frame List Rollover Enable* bit in the USB.USBINTR register is set to a one, the host controller issues a hardware interrupt. This interrupt is not delayed to the next interrupt threshold.

#### 11.4.4.3.15.2.3 Interrupt on Async Advance

This event is used for deterministic removal of queue heads from the asynchronous schedule. Whenever the host controller advances the on-chip context of the asynchronous schedule, it evaluates the value of the *Interrupt on Async Advance Doorbell* bit in the USB.USBCMD register.

If it is a one, it sets the *Interrupt on Async Advance* bit in the USB.USBSTS register to a one. If the *Interrupt on Async Advance Enable* bit in the USB.USBINTR register is a one, the host controller issues a hardware interrupt at the next interrupt threshold. A detailed explanation of this feature is described in Section [Removing Queue Heads from Asynchronous Schedule](#) .

#### 11.4.4.3.15.2.4 Host System Error

The host controller is a bus master and any interaction between the host controller and the system may experience errors.

The type of host error may be catastrophic to the host controller (such as a Master Abort) making it impossible for the host controller to continue in a coherent fashion. In the presence of non-catastrophic host errors, such as parity errors, the host controller could potentially continue operation. The recommended behavior for these types of errors is to escalate it to a catastrophic error and halt the host controller. Host-based error must result in the following actions:

- The *Run/Stop* bit in the USB.USBCMD register is set to a zero.
- The following bits in the USB.USBSTS register are set:
  - *Host System Error* bit is to a one.
  - *HCHalted* bit is set to a one.
- If the *Host System Error Enable* bit in the USB.USBINTR register is a one, then the host controller will issue a hardware interrupt. This interrupt is not delayed to the next interrupt threshold. The following table summarizes the required actions taken on the various host errors.

**Table 11-109. Summary Behavior of EHCI Host Controller on Host System Errors**

Cycle Type	Master Abort	Target Abort	Data Phase Parity
Frame list pointer fetch (read)	Fatal	Fatal	Fatal [o]
siTD fetch (read)	Fatal	Fatal	Fatal [o]
siTD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
iTD fetch (read)	Fatal	Fatal	Fatal [o]
iTD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
qTD fetch (read)	Fatal	Fatal	Fatal [o]
qHD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
Data write	Fatal [o]	Fatal [o]	Fatal [o]
Data read	Fatal	Fatal	Fatal [o]

Potentially, a host controller implementation could continue operation without a halt. However, the recommended behavior is to halt the host controller.

#### NOTE

After a *Host System Error*, Software must reset the host controller through *HCRreset* in the USB.USBCMD register before re-initializing and restarting the host controller.

#### 11.4.4.4 EHCI Deviation

For the purposes a dual-role Host/Device controller with support for On-The-Go applications, it is necessary to deviate from the EHCI specification. Enhanced Host Controller Interface Specification for Universal Serial Bus, Revision 0.95, November 2000, Intel Corporation. <http://www.intel.com>. Device operation & On-The-Go operation is not specified in the EHCI and thus the implementation supported in this core is proprietary.

The host mode operation of the core is near EHCI compatible with few minor differences documented in this section.

The particulars of the deviations occur in the areas summarized here:

- Embedded Transaction Translator - Allows direct attachment of FS and LS devices in host mode without the need for a companion controller.
- Device operation - In host mode the device operational registers are generally disabled and thus device mode is mostly transparent when in host mode. However, there are a couple exceptions documented in the following sections.
- Embedded design interface - This core does not have a PCI Interface and therefore the PCI configuration registers described in the EHCI specification are not applicable.
- On-The-Go Operation - This design includes an On-The-Go controller for Port #1.

##### 11.4.4.4.1 Embedded Transaction Translator Function

The OTG controller supports directly connected full and low speed devices without requiring a companion controller by including the capabilities of a USB 2.0 high speed hub transaction translator.

Although there is no separate Transaction Translator block in the system, the transaction translator function normally associated with a high speed hub has been implemented within the DMA and Protocol engine blocks. The embedded transaction translator function is an extension to EHCI interface, but makes use of the standard data structures and operational models that exist in the EHCI specification to support full and low speed devices.

###### 11.4.4.4.1.1 Capability Registers

The following additions have been added to the capability registers to support the embedded Transaction Translator Function:

- N\_TT added to USB.HCSPARAMS - Host Control Structural Parameters
- N\_PTT added to USB.HCSPARAMS - Host Control Structural Parameters

#### 11.4.4.4.1.2 Operational Registers

The following additions have been added to the operational registers to support the embedded TT:

- Addition of two-bit Port Speed (PSPD) to the register.

#### 11.4.4.4.1.3 Discovery-EHCI Deviation

In a standard EHCI controller design, the EHCI host controller driver detects a Full speed (FS) or Low speed (LS) device by noting if the port enable bit is set after the port reset operation.

The port enable will only be set in a standard EHCI controller implementation after the port reset operation and when the host and device negotiate a High-Speed connection (that is, Chirp completes successfully).

Because this controller has an embedded Transaction Translator, the port enable will always be set after the port reset operation regardless of the result of the host device chirp result and the resulting port speed will be indicated by the PSPD field in USB.PORTSCx.

Therefore, the standard EHCI host controller driver requires an alteration to handle directly connected Full and Low speed devices or hubs.

The change is a fundamental one in that is summarized in the following table.

**Table 11-110. Summary of EHCI**

Standard EHCI	EHCI with embedded Transaction Translator
After port enable bit is set following a connection and reset sequence, the device/hub is assumed to be HS.	After port enable bit is set following a connection and reset sequence, the device/hub speed is noted from USB.PORTSCx.
FS and LS devices are assumed to be downstream from a HS hub thus, all port-level control is performed through the Hub Class to the nearest Hub.	FS and LS device can be either downstream from a HS hub or directly attached. When the FS/LS device is downstream from a HS hub, then port-level control is done using the Hub Class through the nearest Hub. When a FS/LS device is directly attached, then port-level control is accomplished using USB.PORTSCx.
FS and LS devices are assumed to be downstream from a HS hub with HubAddr=X. [where HubAddr > 0 and HubAddr is the address of the Hub where the bus transitions from HS to FS/LS (ie. Split target hub)]	FS and LS device can be either downstream from a HS hub with HubAddr = X [HubAddr > 0] or directly attached [where HubAddr = 0 and HubAddr is the address of the Root Hub where the bus transitions from HS to FS/LS (ie. Split target hub is the root hub) ]

#### 11.4.4.4.1.4 Data Structures

The same data structures used for FS/LS transactions through a HS hub are also used for transactions through the Root Hub with sm embedded Transaction Translator.

Here it is demonstrated how the Hub Address and Endpoint Speed fields should be set for directly attached FS/LS devices and hubs:

1. QH (for direct attach FS/LS) - Async. (Bulk/Control Endpoints) Periodic (Interrupt)
  - Hub Address = 0
  - Transactions to direct attached device/hub.
    - QH.EPS = Port Speed
  - Transactions to a device downstream from direct attached FS hub.
    - QH.EPS = Downstream Device Speed

#### NOTE

When QH.EPS = 01 (LS) and PORTSCx.PSPD = 00 (FS), a LS-pre-pid will be sent before the transmitting LS traffic.

Maximum Packet Size must be less than or equal 64 or undefined behaviour may result.

2. siTD (for direct attach FS) - Periodic (ISO Endpoint)
  - All FS ISO transactions:
    - Hub Address = 0
    - siTD.EPS = 00 (full speed)
      - Maximum Packet Size must less than or equal to 1023 or undefined behaviour may result.

#### 11.4.4.4.1.5 Operational Model

The operational models are well defined for the behavior of the Transaction Translator (see USB 2.0 specification. Universal Serial Bus Specification, Revision 2.0, April 2000, Compaq, Hewlett-Packard, Intel, Lucent, Microsoft, NEC, Philips. <http://www.usb.org>) and for the EHCI controller moving packets between system memory and a USB-HS hub. Because the embedded Transaction Translator exists within the host controller there is no physical bus between EHCI host controller driver and the USB FS/LS bus. These sections will briefly discuss the operational model for how the EHCI and Transaction Translator operational models are combined without the physical bus between. The following sections assume the reader is familiar with both the EHCI and USB 2.0 Transaction Translator operational models.

#### 11.4.4.4.1.5.1 Micro-frame Pipeline

The EHCI operational model uses the concept of H-frames and B-frames to describe the pipeline between the Host (H) and the Bus (B). The embedded Transaction Translator shall use the same pipeline algorithms specified in the USB 2.0 specification for a Hub-based Transaction Translator.

All periodic transfers always begin at B-frame 0 (after SOF) and continue until the stored periodic transfers are complete. As an example of the micro-frame pipeline implemented in the embedded Transaction Translator, all periodic transfers that are tagged in EHCI to execute in H-frame 0 will be ready to execute on the bus in B-frame 0.

It is important to note that when programming the S-mask and C-masks in the EHCI data structures to schedule periodic transfers for the embedded Transaction Translator, the EHCI host controller driver must follow the same rules specified in EHCI for programming the S-mask and C-mask for downstream Hub-based Transaction Translators.

Once periodic transfers are exhausted, any stored asynchronous transfer will be moved. Asynchronous transfers are opportunistic in that they shall execute whenever possible and their operation is not tied to H-frame and B-frame boundaries with the exception that an asynchronous transfer can not babble through the SOF (start of B-frame 0.)

#### 11.4.4.4.1.5.2 Split State Machines

The start and complete split operational model differs from EHCI slightly because there is no bus medium between the EHCI controller and the embedded Transaction Translator.

Where a start or complete-split operation would occur by requesting the split to the HS hub, the start/complete split operation is simple an internal operation to the embedded Transaction Translator. The following table summarizes the conditions where handshakes are emulated from internal state instead of actual handshakes to HS split bus traffic.

**Table 11-111. Summary of the Conditions of Handshakes<sup>1</sup>**

Condition	Emulate TT Response
Start-Split: All asynchronous buffers full.	NAK
Start-Split: All periodic buffers full.	ERR
Start-Split: Success for start of Async. Transaction.	ACK
Start-Split: Start Periodic Transaction.	No Handshake (Ok)
Complete-Split: Failed to find transaction in queue.	Bus Time Out
Complete-Split: Transaction in Queue is Busy.	NYET
Complete-Split: Transaction in Queue is Complete.	[Actual Handshake from LS/FS device]

1. The un-shaded cells represent Start-Splits and the shaded cells represent Complete-Splits

### 11.4.4.4.1.5.3 *Asynchronous Transaction Scheduling and Buffer Management*

The following USB 2.0 specification items are implemented in the embedded Transaction Translator:

#### 11.4.4.4.1.5.3.1 *USB 2.0 - 11.17.3*

- Sequencing is provided & a packet length estimator ensures no full-speed/low-speed packet babbles into SOF time.

#### 11.4.4.4.1.5.3.2 *USB 2.0 - 11.17.4*

- Transaction tracking for 2 data pipes.

### 11.4.4.4.1.5.4 *Periodic Transaction Scheduling and Buffer Management*

The following USB 2.0 specification items are implemented in the embedded Transaction Translator:

#### 11.4.4.4.1.5.4.1 *USB 2.0 - 11.18.6.[1-2]*

- Abort of pending start-splits
  - EOF (and not started in micro-frames 6)
  - Idle for more than 4 micro-frames
- Abort of pending complete-splits
  - EOF
  - Idle for more than 4 micro-frames

#### 11.4.4.4.1.5.4.2 *USB 2.0 - 11.18.[7-8]*

- Transaction tracking for up to 16 data pipes.
- Complete-split transaction searching.

### **NOTE**

There is no data schedule mechanism for these transactions other than the micro-frame pipeline. The embedded TT assumes the number of packets scheduled in a frame does not exceed the frame duration (1 ms) or else undefined behavior may result.

### 11.4.4.4.1.5.5 *Multiple Transaction Translators*

The maximum number of embedded Transaction Translators that is currently supported is one as indicated by the N\_TT field in the register.

#### 11.4.4.4.2 Device Operation

The co-existence of a device operational controller within the host controller has little effect on EHCI compatibility for host operation except as noted in this section.

##### 11.4.4.4.2.1 USB\_USBMODE Register

Given that the dual-role controller is initialized in neither host nor device mode, the [USB Device Mode \(USB\\_USBMODE\)](#) register must be programmed for host operation before the EHCI host controller driver can begin EHCI host operations.

##### 11.4.4.4.2.2 Non-Zero Fields the Register File

Some of the reserved fields and reserved addresses in the capability registers and operational register have use in device mode, the following must be adhered to:

- Write operations to all EHCI reserved fields (some of which are device fields) with the operation registers should always be written to zero. This is an EHCI requirement of the device controller driver that must be adhered to.
- Read operations by the host controller must properly mask EHCI reserved fields (some of which are device fields) because fields that are used exclusive for device are undefined in host mode .

##### 11.4.4.4.2.3 SOF Interrupt

This SOF Interrupt used for device mode is shared as a free running 125us interrupt for host mode.

EHCI does not specify this interrupt but it has been added for convenience and as a potential software time base. See and registers.

##### 11.4.4.4.3 Embedded Design Interface

This is an Embedded USB Host Controller as defined by the EHCI specification and thus does not implement the PCI configuration registers.

#### 11.4.4.4.3.1 Frame Adjust Register

Given that the optional PCI configuration registers are not included in this implementation, there is no corresponding bit level timing adjustments like is provided by the Frame Adjust register in the PCI configuration registers. Starts of micro-frames are timed precisely to 125 us using the transceiver clock as a reference clock. That is, a 60 Mhz transceiver clock for 8-bit physical interfaces & full-speed serial interfaces or 30 Mhz transceiver clock for 16-bit physical interfaces.

#### 11.4.4.4.4 Miscellaneous variations from EHCI

##### 11.4.4.4.4.1 Programmable Physical Interface Behaviour

This design supports multiple Physical interfaces which can operate in differing modes when the core is configured with software programmable Physical Interface Modes.

Software programmability allows the selection of the Physical interface part during the board design phase instead of during the chip design phase.

The control bits for selecting the Physical Interface operating mode have been added to the register providing a capability that is not defined by EHCI.

##### 11.4.4.4.4.2 Discovery

###### 11.4.4.4.4.2.1 Port Reset

The port connect methods specified by EHCI require setting the port reset bit in the register for a duration of 10ms. Due to the complexity required to support the attachment of devices that are not high speed there are counter already present in the design that can count the 10ms reset pulse to alleviate the requirement of the software to measure this duration. Therefore, the basic connection is then summarized as the following:

- [Port Change Interrupt] Port connect change occurs to notify the host controller driver that a device has attached.
- Software shall write a '1' to reset the device.
- Software shall write a '0' to reset the device after 10 ms.
  - This step, which is necessary in a standard EHCI design, may be omitted with this implementation. Should the EHCI host controller driver attempt to write a '0' to the reset bit while a reset is in progress, the write will simple be ignored and the reset will continue until completion.
- [Port Change Interrupt] Port enable change occurs to notify the host controller that the device is now operational and at this point the port speed has been determined.

#### 11.4.4.4.2.2 Port Speed Detection

After the port change interrupt indicates that a port is enabled, the EHCI stack should determine the port speed. Unlike the EHCI implementation, which will re-assign the port owner for any device that does not connect at High-Speed, this host controller supports direct attach of non High-Speed devices.

Therefore, the following differences are important regarding port speed detection:

- Port Owner is read-only and always reads 0.
- A 2-bit Port Speed indicator has been added to PORTSC to provide the current operating speed of the port to the host controller driver.
- A 1-bit High Speed indicator has been added to PORTSC to signify that the port is in High-Speed vs. Full/Low Speed - *This information is redundant with the 2-bit Port Speed indicator above.*

#### 11.4.4.4.3 Port Test Mode

Port Test Control mode behaves fully as described in EHCI. An alternate host controller driver procedure is not necessary or supported.

### 11.4.4.5 Device Data Structures

This section defines the interface data structures used to communicate control, status, and data between Device Controller Driver (DCD) Software and the Device Controller.

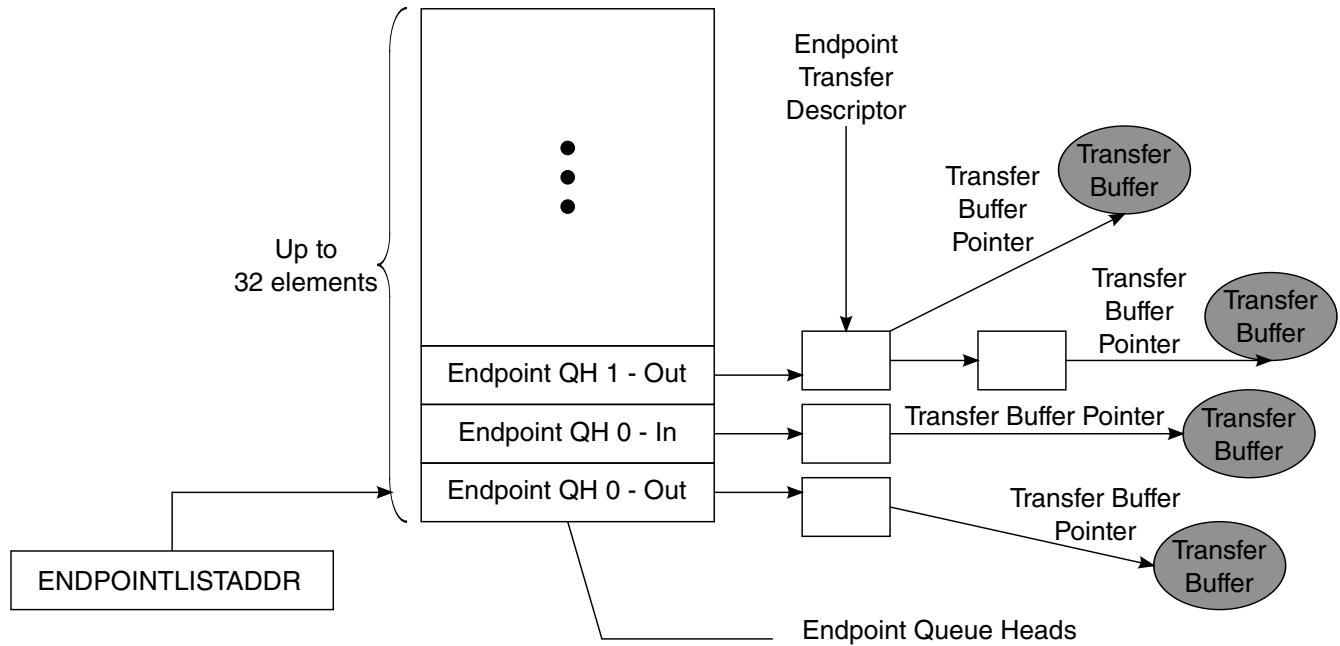

The data structure definitions in this chapter support a 32-bit memory buffer address space. The interface consists of device Queue Heads and Transfer Descriptors.

#### NOTE

Software must ensure that no interface data structure reachable by the Device Controller spans a 4K-page boundary.

The data structures defined in the chapter are (from the device controller's perspective) a mix of read-only and read/ writable fields. The device controller must preserve the read-only fields on all data structure writes.

The figure below shows the organization of the EndPoint Queue Head.

**Figure 11-86. EndPoint Queue Head Organization**

Endpoint queue heads are arranged in an array in a continuous area of memory pointed to by the `USB.ENDPOINTLISTADDR` pointer. The even -numbered device queue heads in the list support receive endpoints (OUT/SETUP) and the odd-numbered queue heads in the list are used for transmit endpoints (IN/INTERRUPT). The device controller will index into this array based upon the endpoint number received from the USB bus. All information necessary to respond to transactions for all primed transfers is contained in this list so the Device Controller can readily respond to incoming requests without having to traverse a linked list.

**NOTE**

The Endpoint Queue Head List must be aligned to a 2k boundary.

**11.4.4.5.1 Endpoint Queue Head (dQH)**

The device Endpoint Queue Head (dQH) is where all transfers for a given endpoint are managed. The dQH is a 48-byte data structure, but must be aligned on 64-byte boundaries.

During priming of an endpoint, the dTD (device transfer descriptor) is copied into the overlay area of the dQH, which starts at the `nextTD` pointer DWord and continues through the end of the buffer pointers DWords. After a transfer is complete, the dTD

status DWord is updated in the dTD pointed to by the currentTD pointer. While a packet is in progress, the overlay area of the dQH is used as a staging area for the dTD so that the Device Controller can access needed information with little minimal latency.

**Table 11-112. Endpoint Queue Head (dQH)**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Host Controller Read Only

#### 11.4.4.5.1.1 Endpoint Capabilities/Characteristics

This DWord specifies static information about the endpoint, in other words, this information does not change over the lifetime of the endpoint. Device Controller software should not attempt to modify this information while the corresponding endpoint is enabled.

[Table 11-113](#) describes the endpoint capabilities.

**Table 11-113. Endpoint Capabilities/Characteristics**

Bit	Description
-----	-------------

*Table continues on the next page...*

**Table 11-113. Endpoint Capabilities/Characteristics (continued)**

31-30	Mult. This field is used to indicate the number of packets executed per transaction description as given by the following:  00 - Execute N Transactions as demonstrated by the USB variable length packet protocol where N is computed using the Maximum Packet Length (dQH) and the Total Bytes field (dTD)  01 Execute 1 Transaction. 10 Execute 2 Transactions. 11 Execute 3 Transactions.  <b>NOTE:</b> Non-ISO endpoints must set Mult="00". ISO endpoints must set Mult="01", "10", or "11" as needed.
29	Zero Length Termination Select. This bit is used to indicate when a zero length packet is used to terminate transfers where to total transfer length is a multiple . This bit is not relevant for Isochronous  0 - Enable zero length packet to terminate transfers equal to a multiple of the Maximum Packet Length. (default).  1 - Disable the zero length packet on transfers that are equal in length to a multiple Maximum Packet Length.
28-27	Reserved. These bit reserved for future use and should be set to zero.
26-16	Maximum Packet Length. This directly corresponds to the maximum packet size of the associated endpoint (wMaxPacketSize). The maximum value this field may contain is 0x400 (1024).
15	Interrupt On Setup (IOS). This bit is used on control type endpoints to indicate if USBINT is set in response to a setup being received.
14-0	Reserved. Bits reserved for future use and should be set to zero.

#### 11.4.4.5.1.2 Transfer Overlay-Endpoint Queue Head

The seven DWords in the overlay area represent a transaction working space for the device controller.

The general operational model is that the device controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, then it will not read the associated endpoint.

After an endpoint is readied, the dTD will be copied into this queue head overlay area by the device controller. Until a transfer is expired, software must not write the queue head overlay area or the associated transfer descriptor. When the transfer is complete, the device controller will write the results back to the original transfer descriptor and advance the queue.

See dTD for a description of the overlay fields.

#### 11.4.4.5.1.3 Current dTD Pointer

The current dTD pointer is used by the device controller to locate the transfer in progress. This word is for Device Controller (hardware) use only and should not be modified by DCD software.

The following table describes the dTD Pointer.

**Table 11-114. Next dTD Pointer**

Bit	Description
31-5	Current dTD. This field is a pointer to the dTD that is represented in the transfer overlay area. This field will be modified by the Device Controller to next dTD pointer during endpoint priming or queue advance.
4-0	Reserved. Bit reserved for future use and should be set to zero.

#### 11.4.4.5.1.4 Set-up Buffer

The set-up buffer is dedicated storage for the 8-byte data that follows a set-up PID.

#### NOTE

Each endpoint has a TX and an RX dQH associated with it, and only the RX queue head is used for receiving setup data packets.

The following table describes the Multiple Mode Control.

**Table 11-115. Multiple Mode Control (HCCPARAMS)**

DWord	Bits	Description
1	31-0	Setup Buffer 0. This buffer contains bytes 3 to 0 of an incoming setup buffer packet and is written by the device controller to be read by software.
2	31-0	Setup Buffer 1. This buffer contains bytes 7 to 4 of an incoming setup buffer packet and is written by the device controller to be read by software.

#### 11.4.4.5.2 Endpoint Transfer Descriptor (dTD)

The dTD describes to the device controller the location and quantity of data to be sent/received for a given transfer.

The DCD should not attempt to modify any field in an active dTD except the Next Like Pointer, which should only be modified as described in section [Managing Transfers with Transfer Descriptors](#).

Table below shows the Endpoint Transfer Descriptor (dTD).

**Table 11-116. Endpoint Transfer Descriptor (dTD)**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Buffer Pointer (Page 0)																		Current Offset													

*Table continues on the next page...*

**Table 11-116. Endpoint Transfer Descriptor (dTD) (continued)**

Buffer Pointer (Page 1)	0	Frame Number
Buffer Pointer (Page 2)	Reserved	
Buffer Pointer (Page 3)	Reserved	
Buffer Pointer (Page 4)	Reserved	

Host Controller Read/Write

Host Controller Read Only

The following table describes the dTD Pointer.

**Table 11-117. Next dTD Pointer**

Bit	Description
31-5	Next Transfer Element Pointer. This field contains the physical memory address of the next dTD to be processed. The field corresponds to memory address signals [31:5], respectively.
4-1	Reserved. Bits reserved for future use and should be set to zero.
0	Terminate (T). 1=pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Device Controller that there are no more valid entries in the queue.

The following table describes the dTD Token.

**Table 11-118. dTD Token**

Bit	Description
31	Reserved. Bit reserved for future use and should be set to zero.
30-16	Total Bytes. This field specifies the total number of bytes to be moved with this transfer descriptor. This field is decremented by the number of bytes actually moved during the transaction and only on the successful completion of the transaction.  The maximum value software may store in the field is 5*4K (5000H). This is the maximum number of bytes 5 page pointers can access. Although it is possible to create a transfer up to 20K this assumes the 1 <sup>st</sup> offset into the first page is 0. When the offset cannot be predetermined, crossing past the 5th page can be guaranteed by limiting the total bytes to 16K**. Therefore, the maximum recommended transfer is 16K (4000H).  If the value of the field is zero when the host controller fetches this transfer descriptor (and the active bit is set), the device controller executes a zero-length transaction and retires the transfer descriptor.  It is not a requirement for IN transfers that Total Bytes To Transfer be an even multiple of <i>Maximum Packet Length</i> . If software builds such a transfer descriptor for an IN transfer, the last transaction will always be less than <i>Maximum Packet Length</i> .
15	Interrupt On Complete (IOC). This bit is used to indicate if USBINT is to be set in response to device controller being finished with this dTD.
14-12	Reserved. Bits reserved for future use and should be set to zero.
11-10	Multiplier Override (MultO). This field can be used for transmit ISO's (ie. ISO-IN) to override the multiplier in the QH. This field must be zero for all packet types that are not transmit-ISO.  Example:

*Table continues on the next page...*

**Table 11-118. dTD Token (continued)**

	<p>if QH.multiplier = 3; Maximum packet size = 8; Total Bytes = 15; MultiO = 0 [default]  Three packets are sent: {Data2(8); Data1(7); Data0(0)}</p> <p>if QH.multiplier = 3; Maximum packet size = 8; Total Bytes = 15; MultiO = 2  Two packets are sent: {Data1(8); Data0(7)}</p> <p>For maximal efficiency, software should compute MultiO = greatest integer of (Total Bytes / Max. Packet Size) except for the case when Total Bytes = 0; then MultiO should be 1.</p> <p>Note: Non-ISO and Non-TX endpoints must set MultiO = "00".</p>
9-8	Reserved. Bits reserved for future use and should be set to zero.
7-0	<p>Status. This field is used by the Device Controller to communicate individual command execution states back to the Device Controller software. This field contains the status of the last transaction performed on this qTD. The bit encodings are:</p> <p>Bit Status Field Description</p> <p>7 Active.</p> <p>6 Halted.</p> <p>5 Data Buffer Error.</p> <p>3 Transaction Error.</p> <p>4, 2, 0 Reserved.</p>

The table below describes the dTD Buffer Page Pointer List.

**Table 11-119. dTD Buffer Page Pointer List**

Bit	Description
31-12	Buffer Pointer. Selects the page offset in memory for the packet buffer. Non virtual memory systems will typically set the buffer pointers to a series of incrementing integers.
0,11-0	Current Offset. Offset into the 4kb buffer where the packet is to begin.
1,10-0	Frame Number. Written by the device controller to indicate the frame number in which a packet finishes. This is typically be used to correlate relative completion times of packets on an ISO endpoint.

#### 11.4.4.6 Device Operational Model

The function of the device operation is to transfer a request in the memory image to and from the Universal Serial Bus.

Using a set of linked list transfer descriptors, pointed to by a queue head, the device controller will perform the data transfers. The following sections explain the use of the device controller from the device controller driver (DCD) point-of-view and further describe how specific USB bus events relate to status changes in the device controller programmer's interface.

### 11.4.4.6.1 Device Controller Initialization

After hardware reset, the device is disabled until the Run/Stop bit is set to a '1'. In the disabled state, the pull-up on the USB D+ is not active which prevents an attach event from occurring. At a minimum, it is necessary to have the queue heads setup for endpoint zero before the device attach occurs.

Shortly after the device is enabled, a USB reset will occur followed by setup packet arriving at endpoint 0. A Queue head must be prepared so that the device controller can store the incoming setup packet.

In order to initialize a device, the software should perform the following steps:

- Set Controller Mode in the USB.USBMODE register to device mode.

#### NOTE

Transitioning from host mode to device mode requires a device controller reset before modifying USB.USBMODE.

- Allocate and Initialize device queue heads in system memory.
  - Minimum: Initialize device queue heads 0 Tx & 0 Rx.

#### NOTE

All device queue heads for control endpoints must be initialized before the endpoint is enabled. Non-Control device queue heads before the endpoint can be used.

- For information on device queue heads, refer to section [Device Data Structures](#).
- Configure USB.ENDPOINTLISTADDR Pointer.
  - For additional information on USB.ENDPOINTLISTADDR, refer to the register table.
- Enable the microprocessor interrupt associated with the USB core.
  - Recommended: enable all device interrupts including: USBINT, USBERRINT, Port Change Detect, USB Reset Received, DCSuspend.
  - For a list of available interrupts refer to the and the register tables.
- Set Run/Stop bit to Run Mode.
  - After the Run bit is set and the device is connected to a host, a Bus Reset will be issued by host downstream port. The DCD must monitor the reset event and adjust the software state as described in the Bus Reset section of the Port State and Control section below.

#### NOTE

Endpoint 0 is designed as a control endpoint only and does not need to be configured using ENDPTCTRL0 register.

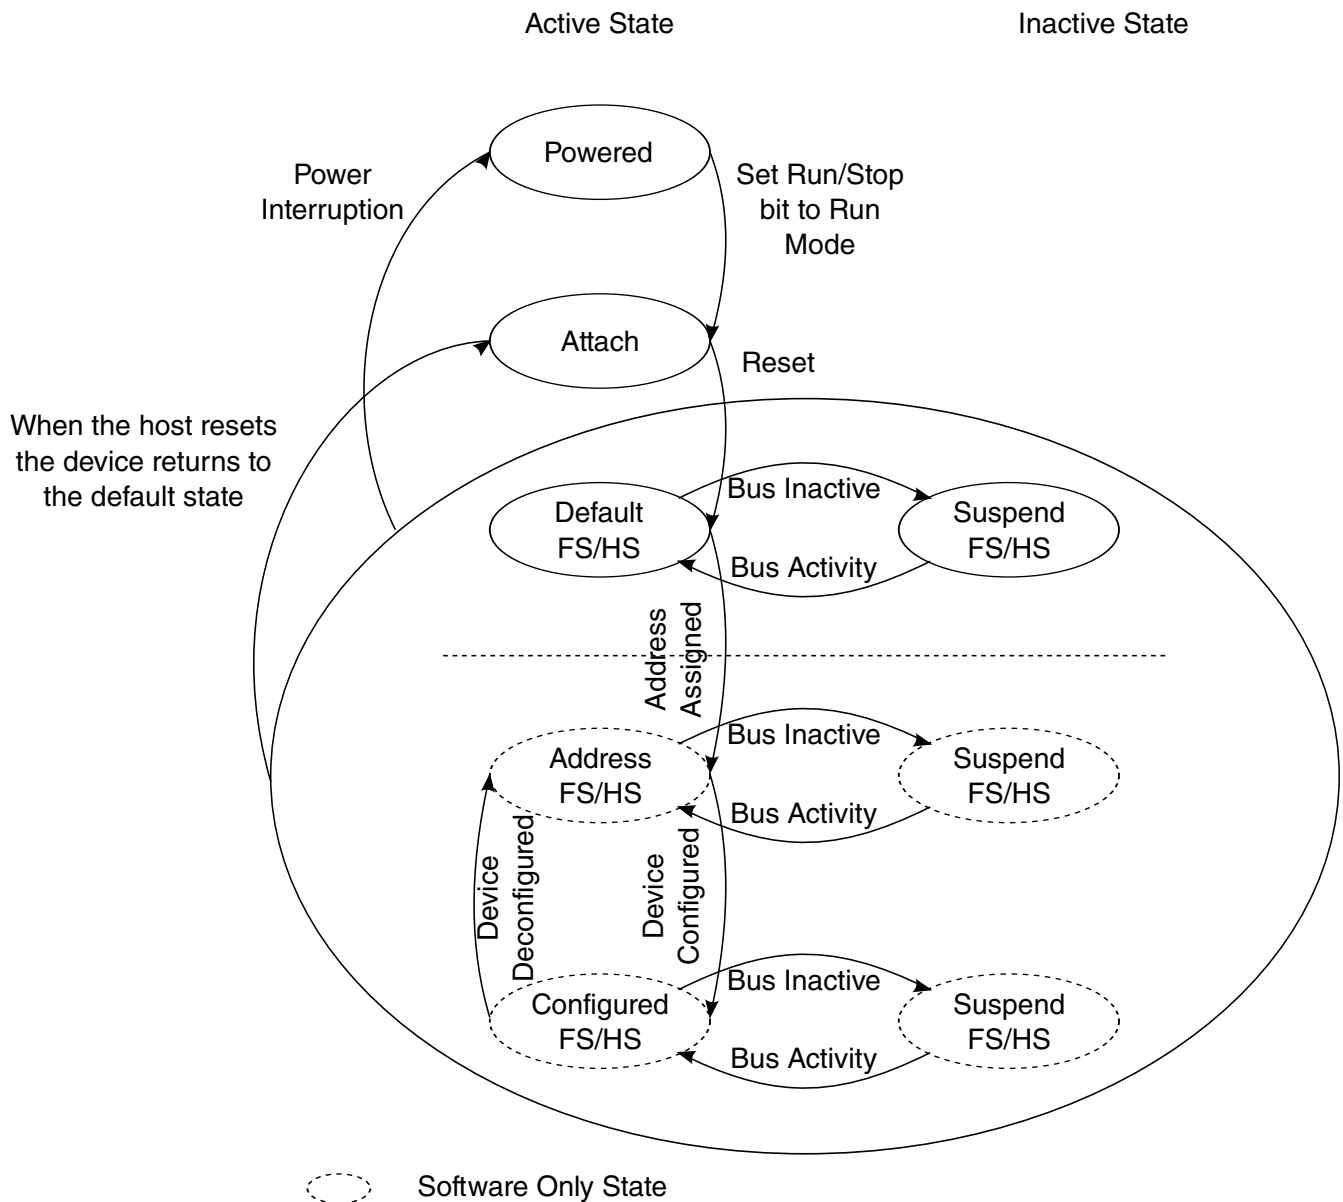

It is also not necessary to prime Endpoint 0 initially because the first packet received will always be a setup packet. The contents of the first setup packet will require a response in accordance with USB device framework (Chapter 9) command set.

#### 11.4.4.6.2 Port State and Control

From a chip or system reset, the device controller enters the *powered* state. A transition from the *powered* state to the *attach* state occurs when the Run/Stop bit is set to a '1'.

After receiving a reset on the bus, the port will enter the *defaultFS* or *defaultHS* state in accordance with the reset protocol described in Appendix C.2 of the USB Specification Rev. 2.0.

The following state diagram depicts the state of a USB 2.0 device.

**Figure 11-87. Device State Diagram**

States *powered*, *attach*, *defaultFS/HS*, *suspendFS/HS* are implemented in the device controller and are communicated to the DCD using the following status bits:

The following table describes the Device Controller State Information Bits.

**Table 11-120. Device Controller State Information Bits**

Bit	Register
DCSuspend	
USB Reset Received	
Port Change Detect	
High-Speed Port	

It is the responsibility of the DCD to maintain a state variable to differentiate between the *DefaultFS/HS* state and the *Address/Configured* states. Change of state from *Default* to *Address* and the *Configured* states is part of the enumeration process described in the device framework section of the USB 2.0 Specification.

As a result of entering the *Address* state, the device address register (DEVICEADDR) must be programmed by the DCD.

Entry into the *Configured* indicates that all endpoints to be used in the operation of the device have been properly initialized by programming the USB\_UOG\_ENDPTCTRLx registers and initializing the associated queue heads.

#### 11.4.4.6.2.1 Bus Reset

A bus reset is used by the host to initialize downstream devices.

When a bus reset is detected, the device controller will renegotiate its attachment speed, reset the device address to 0, and notify the DCD by interrupt (assuming the USB Reset Interrupt Enable is set). After a reset is received, all endpoints (except endpoint 0) are disabled and any primed transactions will be cancelled by the device controller. The concept of priming will be clarified below, but the DCD must perform the following tasks when a reset is received:

Clear all setup token semaphores by reading the register and writing the same value back to the register.

Clear all the endpoint complete status bits by reading the register and writing the same value back to the register.

Cancel all primed status by waiting until all bits in the are 0 and then writing 0xFFFFFFFF to [Endpoint Flush \(USB\\_ENDPTFLUSH\)](#).

Read the reset bit in the register and make sure that it is still active. A USB reset will occur for a minimum of 3 ms and the DCD must reach this point in the reset cleanup before end of the reset occurs, otherwise a hardware reset of the device controller is recommended (rare.)

- A hardware reset can be performed by writing a one to the device controller reset bit in the USBCMD reset. Note: a hardware reset will cause the device to detach from the bus by clearing the Run/Stop bit. Thus, the DCD must completely re-initialize the device controller after a hardware reset.

Free all allocated dTDs because they will no longer be executed by the device controller. If this is the first time the DCD is processing a USB reset event, then it is likely that no dTDs have been allocated.

At this time, the DCD may release control back to the OS because no further changes to the device controller are permitted until a Port Change Detect is indicated.

After a Port Change Detect, the device has reached the default state and the DCD can read the to determine if the device is operating in FS or HS mode. At this time, the device controller has reached normal operating mode and DCD can begin enumeration according to the USB Chapter 9 - Device Framework.

### NOTE

The device DCD may use the FS/HS mode information to determine the bandwidth mode of the device

In some applications, it may not be possible to enable one or more pipes while in FS mode. *Beyond the data rate issue, there is no difference in DCD operation between FS and HS modes.*

## 11.4.4.6.2.2 Suspend/Resume

### 11.4.4.6.2.2.1 Suspend

#### Suspend Description

In order to conserve power, USB devices automatically enter the suspended state when the device has observed no bus traffic for a specified period. When suspended, the USB device maintains any internal status, including its address and configuration. Attached devices must be prepared to suspend at any time they are powered, regardless of if they have been assigned a non-default address, are configured, or neither. Bus activity may cease due to the host entering a suspend mode of its own. In addition, a USB device shall also enter the suspended state when the hub port it is attached to is disabled.

A USB device exits suspend mode when there is bus activity. A USB device may also request the host to exit suspend mode or selective suspend by using electrical signaling to indicate remote wakeup. The ability of a device to signal remote wakeup is optional. If the USB device is capable of remote wakeup signaling, the device must support the ability of the host to enable and disable this capability. When the device is reset, remote wakeup signaling must be disabled.

#### Suspend Operational Model

The device controller moves into the suspend state when suspend signaling is detected or activity is missing on the upstream port for more than a specific period. After the device controller enters the suspend state, the DCD is notified by an interrupt (assuming *DC Suspend Interrupt* is enabled). When the *DCSuspend* bit in the is set to a '1', the device controller is suspended.

DCD response when the device controller is suspended is application specific and may involve switching to low power operation.

Information on the bus power limits in suspend state can be found in USB 2.0 specification.

### NOTE

Review system level clocking issues defined in section (Ref: Signals-Clocking) for the clocking requirements of a suspended device controller.

#### 11.4.4.6.2.2.2 Resume

If the device controller is suspended, its operation is resumed when any non-idle signaling is received on its upstream facing port. In addition, the device can signal the system to resume operation by forcing resume signaling to the upstream port.

Resume signaling is sent upstream by writing a '1' to the Resume bit in the in the [Port Status & Control \(USB\\_PORTSC1\)](#) while the device is in suspend state. Sending resume signal to an upstream port should cause the host to issue resume signaling and bring the suspended bus segment (one more devices) back to the active condition.

### NOTE

Before resume signaling can be used, the host must enable it by using the Set Feature command defined in device framework (chapter 9) of the USB 2.0 Specification.

### 11.4.4.6.3 Managing Endpoints

The USB 2.0 specification defines an endpoint, also called a device endpoint or an address endpoint as a uniquely addressable portion of a USB device that can source or sink data in a communications channel between the host and the device.

The endpoint address is specified by the combination of the endpoint number and the endpoint direction.

The channel between the host and an endpoint at a specific device represents a data pipe. Endpoint 0 for a device is always a *control* type data channel used for device discovery and enumeration. Other types of endpoints support by USB include *bulk*, *interrupt*, and

*isochronous*. Each endpoint type has specific behavior related to packet response and error handling. More detail on endpoint operation can be found in the USB 2.0 specification.

The USB OTG device controller hardware supports up to 8 endpoint numbers.

Each endpoint direction is essentially independent and can be configured with differing behavior in each direction. For example, the DCD can configure endpoint 1-IN to be a bulk endpoint and endpoint 1-OUT to be an isochronous endpoint. This helps to conserve the total number of endpoints required for device operation. The only exception is that control endpoints must use both directions on a single endpoint number to function as a control endpoint. Endpoint 0 is, for example, is always a control endpoint and uses the pair of directions.

Each endpoint direction requires a *queue head* allocated in memory. To support the 8 endpoint numbers, 16 *queue heads* are required. The operation of an endpoint and use of *queue heads* are described later in this document.

#### 11.4.4.6.3.1 Endpoint Initialization

After hardware reset, all endpoints except endpoint zero are uninitialized and disabled. The DCD must configure and enable each endpoint by writing to configuration bit in the USB\_UOG\_ENDPTCTRLx register.

Each 32-bit USB\_UOG\_ENDPTCTRLx is split into an upper and lower half. The lower half of USB\_UOG\_ENDPTCTRLx is used to configure the receive or OUT endpoint and the upper half is likewise used to configure the corresponding transmit or IN endpoint. Control endpoints must be configured the same in both the upper and lower half of the USB\_UOG\_ENDPTCTRLx register otherwise the behavior is undefined. The following table shows how to construct a configuration word for endpoint initialization. The following table shows the fields and values for the Device Controller Endpoint initialization.

**Table 11-121. Device Controller Endpoint Initialization**

Field	Value
Data Toggle Reset	1
Data Toggle Inhibit	0
Endpoint Type	00 Control 01 Isochronous 10 Bulk 11 Interrupt
Endpoint Stall	0

### 11.4.4.6.3.2 Stalling

There are two occasions where the device controller may need to return to the host a STALL.

The first occasion is the functional stall, which is a condition set by the DCD as described in the USB 2.0 device framework. A functional stall is only used on non-control endpoints and can be enabled in the device controller by setting the endpoint stall bit in the USB\_UOG\_ENDPTCTRLx register associated with the given endpoint and the given direction. In a functional stall condition, the device controller will continue to return STALL responses to all transactions occurring on the respective endpoint and direction until the endpoint stall bit is cleared by the DCD.

A protocol stall, unlike a function stall, is used on control endpoints is automatically cleared by the device controller at the start of a new control transaction (setup phase). When enabling a protocol stall, the DCD should enable the stall bits (both directions) as a pair. A single write to the USB\_UOG\_ENDPTCTRLx register can ensure that both stall bits are set at the same instant.

#### NOTE

Any write to the USB\_UOG\_ENDPTCTRLx register during operational mode must preserve the endpoint type field (that is, perform a read-modify-write).

The following table shows the response matrix for the Device Controller Stall.

**Table 11-122. Device Controller Stall Response Matrix**

USB Packet	Endpoint Stall Bit.	Effect on STALL bit.	USB Response
SETUP packet received by a non-control endpoint.	N/A	None.	STALL
IN/OUT/PING packet received by a non-control endpoint.	'1'	None.	STALL
IN/OUT/PING packet received by a non-control endpoint.	'0'	None.	ACK/ NAK/ NYET
SETUP packet received by a control endpoint.	N/A	Cleared	ACK
IN/OUT/PING packet received by a control endpoint	'1'	None	STALL
IN/OUT/PING packet received by a control endpoint.	'0'	None.	ACK/ NAK/ NYET

### 11.4.4.6.3.3 Data Toggle

Data toggle is a mechanism to maintain data coherency between host and device for any given data pipe.

For more information on data toggle, refer to the USB 2.0 specification.

#### 11.4.4.6.3.3.1 Data Toggle Reset

The DCD may reset the data toggle state bit and cause the data toggle sequence to reset in the device controller by writing a '1' to the data toggle reset bit in the USB\_UOG\_ENDPTCTRLx register.

This should only be necessary when configuring/initializing an endpoint or returning from a STALL condition.

#### 11.4.4.6.3.3.2 Data Toggle Inhibit

### NOTE

This feature is for test purposes only and should never be used during normal device controller operation.

Setting the *data toggle Inhibit bit* active ('1') causes the device controller to ignore the data toggle pattern that is normally sent and accept all incoming data packets regardless of the data toggle state.

In normal operation, the device controller checks the DATA0/DATA1 bit against the data toggle to determine if the packet is valid. If Data PID does not match the data toggle state bit maintained by the device controller for that endpoint, the Data toggle is considered not valid. If the data toggle is not valid, the device controller assumes the packet was already received and discards the packet (not reporting it to the DCD). To prevent the host controller from re-sending the same packet, the device controller will respond to the error packet by acknowledging it with either an ACK or NYET response.

#### 11.4.4.6.3.3.3 Priming Transmit Endpoints

Priming a transmit endpoint will cause the device controller to fetch the device transfer descriptor (dTD) for the transaction pointed to by the device queue head (dQH).

After the dTD is fetched, it will be stored in the dQH until the device controller completes the transfer described by the dTD. Storing the dTD in the dQH allows the device controller to fetch the operating context needed to handle a request from the host without the need to follow the linked list, starting at the dQH when the host request is received.

After the device has loaded the dTD, the leading data in the packet is stored in a FIFO in the device controller. This FIFO is split into virtual channels so that the leading data can be stored for any endpoint up to the maximum number of endpoints configured at device synthesis time.

After a priming request is complete, an endpoint state of primed is indicated in the USB\_UOG\_ENDPTSTATUS register. For a primed transmit endpoint, the device controller can respond to an IN request from the host and meet the stringent bus turnaround time of High Speed USB.

Because only the leading data is stored in the device controller FIFO, it is necessary for the device controller to begin filling in behind leading data after the transaction starts. The FIFO must be sized to account for the maximum latency that can be incurred by the system memory bus. More information about FIFO sizing is presented in section .

#### 11.4.4.6.3.3.4 Priming Receive Endpoints

Priming receive endpoints is identical to priming of transmit endpoints from the point of view of the DCD. At the device controller the major difference in the operational model is that there is no data movement of the leading packet data simply because the data is to be received from the host.

Note as part of the architecture, the FIFO for the receive endpoints is not partitioned into multiple channels like the transmit FIFO. Thus, the size of the RX FIFO does not scale with the number of endpoints.

### 11.4.4.6.4 Operational Model For Packet Transfers

All transactions on the USB bus are initiated by the host and in turn, the device must respond to any request from the host within the turnaround time stated in the USB 2.0 Specification.

At USB 1.1 Full or Low Speed rates, this turnaround time was significant and the USB 1.1 device controllers were architected so that the device controller could access main memory or interrupt a host protocol processor in order to respond to the USB 1.1 transaction. The architecture of the USB 2.0 device controller must be different because same methods will not meet USB 2.0 High-speed turnaround time requirements by simply increasing clock rate.

A USB host will send requests to the device controller in an order that can not be precisely predicted as a single pipeline, so it is not possible to prepare a single packet for the device controller to execute. However, the order of packet requests is predictable when the endpoint number and direction is considered. For example, if endpoint 3 (transmit direction) is configured as a bulk pipe, then we can expect the host will send IN

requests to that endpoint. This device controller is architected in such a way that it can prepare packets for each endpoint/direction in anticipation of the host request. The process of preparing the device controller to send or receive data in response to host initiated transaction on the bus is referred to as "priming" the endpoint. This term will be used throughout the following documentation to describe the device controller operation so the DCD can be architected properly use priming. Further, note that the term "flushing" is used to describe the action of clearing a packet that was queued for execution.

**11.4.4.6.4.1 Interrupt/Bulk Endpoint Operational Model**

The behaviors of the device controller for interrupt and bulk endpoints are identical.

All valid IN and OUT transactions to bulk pipes will handshake with a NAK unless the endpoint had been primed. Once the endpoint has been primed, data delivery will commence.

A dTD will be retired by the device controller when the packets described in the transfer descriptor have been completed. Each dTD describes N packets to be transferred according to the USB Variable Length transfer protocol. The formula and table on the following page describe how the device controller computes the number and length of the packets to be sent/received by the USB vary according to the total number of bytes and maximum packet length.

With Zero Length Termination (ZLT) = 0

$$N = \text{INT}(\text{Number Of Bytes}/\text{Max. Packet Length}) + 1$$

With Zero Length Termination (ZLT) = 1

$$N = \text{MAXINT}(\text{Number Of Bytes}/\text{Max. Packet Length})$$

**Table 11-123. Variable Length Transfer Protocol Example (ZLT = 0)**

Bytes (dTD)	Max. Packet Length (dQH)	N	P1	P2	P3
511	256	2	256	255	
512	256	3	256	256	0
512	512	2	512	0	

**Table 11-124. Variable Length Transfer Protocol Example (ZLT = 1)**

Bytes (dTD)	Max. Packet Length (dQH)	N	P1	P2	P3
511	256	2	256	255	
512	256	2	256	256	
512	512	1	512		

**NOTE**

The MULT field in the dQH must be set to "00" for bulk, interrupt, and control endpoints.

TX-dTD is complete when:

- All packets described dTD were successfully transmitted. \*\*\* Total bytes in dTD will equal zero when this occurs.

RX-dTD is complete when:

- All packets described in dTD were successfully received. \*\*\* Total bytes in dTD will equal zero when this occurs.
- A short packet (number of bytes < maximum packet length) was received. \*\*\* This is a successful transfer completion; DCD must check Total Bytes in dTD to determine the number of bytes that are remaining. From the total bytes remaining in the dTD, the DCD can compute the actual bytes received.
- A long packet was received (number of bytes > maximum packet size) OR (total bytes received > total bytes specified). \*\*\* This is an error condition. The device controller will discard the remaining packet, and set the Buffer Error bit in the dTD. In addition, the endpoint will be flushed and the USBERR interrupt will become active.

On the successful completion of the packet(s) described by the dTD, the active bit in the dTD will be cleared and the next pointer will be followed when the Terminate bit is clear. When the Terminate bit is set, the device controller will flush the endpoint/direction and cease operations for that endpoint/direction.

On the unsuccessful completion of a packet (see long packet above), the dQH will be left pointing to the dTD that was in error. In order to recover from this error condition, the DCD must properly reinitialize the dQH by clearing the active bit and update the nextTD pointer before attempting to re-prime the endpoint.

**NOTE**

All packet level errors such as a missing handshake or CRC error will be retried automatically by the device controller.

There is no required interaction with the DCD for handling such errors.

#### 11.4.4.6.4.1.1 *Interrupt/Bulk Endpoint Bus Response Matrix*

The table below shows the response matrix for Interrupt/Bulk Endpoint Bus.

**Table 11-125. Interrupt/Bulk Endpoint Bus Response Matrix**

	Stall	Not Primed	Primed	Underflow	Overflow
Setup	Ignore	Ignore	Ignore	N/A	N/A
In	STALL	NAK	Transmit	BS Error	N/A
Out	STALL	NAK	Receive + NYET/ACK	N/A	NAK
Ping	STALL	NAK	ACK	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

**NOTE**

BS Error = Force Bit Stuff Error

NYET/ACK - NYET unless the Transfer Descriptor has packets remaining according to the USB variable length protocol then ACK.

SYSERR - System error should never occur when the latency FIFOs are correctly sized and the DCD is responsive.

**11.4.4.6.4.2 Control Endpoint Operation Model**

*11.4.4.6.4.2.1 Setup Phase*

All requests to a control endpoint begin with a setup phase followed by an optional data phase and a required status phase. The device controller will always accept the setup phase unless the setup lockout is engaged.

The setup lockout will engage so that future setup packets are ignored. Lockout of setup packets ensures that while software is reading the setup packet stored in the queue head, that data is not written as it is being read potentially causing an invalid setup packet.

The setup lockout mechanism can be disabled and a new tripwire type semaphore will ensure that the setup packet payload is extracted from the queue head without being corrupted by an incoming setup packet. This is the preferred behavior because ignoring repeated setup packets due to long software interrupt latency would be a compliance issue.

- Disable Setup Lockout by writing 1 to Setup Lockout Mode (SLOM) in . (once at initialization). Setup lockout is not necessary when using the tripwire as described below.

**NOTE**

Leaving the Setup Lockout Mode As 0 will result in pre-2.3 hardware behavior.

- After receiving an interrupt and inspecting to determine that a setup packet was received on a particular pipe:
  - a. Write 1 to clear corresponding bit .
  - b. Write 1 to Setup Tripwire (SUTW) in register.
  - c. Duplicate contents of dQH.SetupBuffer into local software byte array.
  - d. Read Setup TripWire (SUTW) in register. (if set - continue; if cleared - goto 2)
  - e. Write 0 to clear Setup Tripwire (SUTW) in register.
  - f. Process setup packet using local software byte array copy and execute status/handshake phases.

### **NOTE**

After receiving a new setup packet the status and/or handshake phases may still be pending from a previous control sequence. These should be flushed & deallocated before linking a new status and/or handshake dTD for the most recent setup packet.

#### 11.4.4.6.4.2.2 *Data Phase*

Following the setup phase, the DCD must create a device transfer descriptor for the data phase and prime the transfer.

After priming the packet, the DCD must verify a new setup packet has not been received by reading the USB.ENDPTSETUPSTAT register immediately verifying that the prime had completed. A prime will complete when the associated bit in the register is zero and the associated bit in the register is a one. If a prime fails, ie. The bit goes to zero and the [Endpoint Status \(USB\\_ENDPTSTAT\)](#) bit is not set, then the prime has failed. This can only be due to improper setup of the dQH, dTD or a setup arriving during the prime operation. If a new setup packet is indicated after the ENDPTPRIME bit is cleared, then the transfer descriptor can be freed and the DCD must reinterpret the setup packet.

Should a setup arrive after the data stage is primed, the device controller will automatically clear the prime status () to enforce data coherency with the setup packet.

### **NOTE**

- The MULT field in the dQH must be set to "00" for bulk, interrupt, and control endpoints.
- Error handling of data phase packets is the same as bulk packets described previously.

#### 11.4.4.6.4.2.3 *Status Phase*

Similar to the data phase, the DCD must create a transfer descriptor (with byte length equal zero) and prime the endpoint for the status phase.

The DCD must also perform the same checks of the USB.ENDPTSETUPSTAT as described above in the data phase.

**NOTE**

- The MULT field in the dQH must be set to 00 for bulk, interrupt, and control endpoints.
- Error handling of data phase packets is the same as bulk packets described previously.

11.4.4.6.4.2.4 Control Endpoint Bus Response Matrix

Shown in the following table is the device controller response to packets on a control endpoint according to the device controller state.

The table below shows the response matrix for the Control Endpoint Bus.

**Table 11-126. Control Endpoint Bus Response Matrix**

Token Type	Endpoint State					Setup Lockout
	Stall	Not Primed	Primed	Underflow	Overflow	
Setup	ACK	ACK	ACK	N/A	SYSERR	
In	STALL	NAK	Transmit	BS Error	N/A	N/A
Out	STALL	NAK	Receive + NYET/ACK	N/A	NAK	N/A
Ping	STALL	NAK	ACK	N/A	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore	Ignore

BS Error = Force Bit Stuff Error

NYET/ACK - NYET unless the Transfer Descriptor has packets remaining according to the USB variable length protocol then ACK.

SYSERR - System error should never occur when the latency FIFOs are correctly sized and the DCD is responsive.

**11.4.4.6.4.3 Isochronous Endpoint Operational Model**

Isochronous endpoints are used for real-time scheduled delivery of data and their operational model is significantly different than the host throttled Bulk, Interrupt, and Control data pipes.

Real time delivery by the device controller will be accomplished by the following:

- Exactly MULT Packets per (micro) Frame are transmitted/received. Note: MULT is a two-bit field in the device Queue Head. The variable length packet protocol is not used on isochronous endpoints.
- NAK responses are not used. Instead, zero length packets are sent in response to an IN request to an unprimed endpoints. For unprimed RX endpoints, the response to an OUT transaction is to ignore the packet within the device controller.
- Prime requests always schedule the transfer described in the dTD for the next (micro) frame. If the ISO-dTD is still active after that frame, then the ISO-dTD will be held ready until executed or canceled by the DCD.

An EHCI compatible host controller uses the periodic frame list to schedule data exchanges to Isochronous endpoints. The operational model for device mode does not use such a data structure. Instead, the same dTD used for Control/Bulk/Interrupt endpoints is also used for isochronous endpoints. The difference is in the handling of the dTD.

The first difference between bulk and ISO-endpoints is that priming an ISO-endpoint is a delayed operation such that an endpoint will become primed only after a SOF is received. After the DCD writes the prime bit, the prime bit will be cleared as usual to indicate to software that the device controller completed a priming the dTD for transfer. Internal to the design, the device controller hardware masks that prime start until the next frame boundary. This behavior is hidden from the DCD but occurs so that the device controller can match the dTD to a specific (micro)frame.

Another difference with isochronous endpoints is that the transaction must wholly complete in a (micro)frame. Once an ISO transaction is started in a (micro)frame it will retire the corresponding dTD when MULT transactions occur or the device controller finds a fulfillment condition.

The transaction error bit set in the status field indicates a fulfillment error condition. When a fulfillment error occurs, the frame after the transfer failed to complete wholly, the device controller will force retire the ISO-dTD and move to the next ISO-dTD.

It is important to note that fulfillment errors are only caused due to partially completed packets. If no activity occurs to a primed ISO-dTD, the transaction will stay primed indefinitely. This means it is up to software discard transmit ISO-dTDs that pile up from a failure of the host to move the data.

Finally, the last difference with ISO packets is in the data level error handling. When a CRC error occurs on a received packet, the packet is not retried similar to bulk and control endpoints. Instead, the CRC is noted by setting the *Transaction Error* bit and the data is stored as usual for the application software to sort out.

- TX Packet Retired
  - MULT counter reaches zero.
  - Fulfillment Error [*Transaction Error* bit is set]

- # Packets Occurred > 0 AND # Packets Occurred < MULT

**NOTE**

For TX-ISO, MULT Counter can be loaded with a lesser value in the dTD Multiplier Override field in hardware versions 2.3 and later. If the Multiplier Override is zero, the MULT Counter is initialized to the Multiplier in the QH.

- RX Packet Retired:
  - MULT counter reaches zero.
  - Non-MDATA Data PID is received\*\*
    - \*\* Exit criteria only valid in hardware version 2.3 or later. Previous to hardware version 2.3, any PID sequence that did not match the MULT field exactly would be flagged as a transaction error due to PID mismatch or fulfillment error.
  - Overflow Error:
    - Packet received is > maximum packet length. [*Buffer Error* bit is set]
    - Packet received exceeds total bytes allocated in dTD. [*Buffer Error* bit is set]
  - Fulfillment Error [*Transaction Error* bit is set]
    - # Packets Occurred > 0 AND # Packets Occurred < MULT
  - CRC Error [*Transaction Error* bit is set]

**NOTE**

For ISO, when a dTD is retired, the next dTD is primed for the next frame. For continuous (micro)frame to (micro)frame operation the DCD should ensure that the dTD linked-list is out ahead of the device controller by at least two (micro)frames.

11.4.4.6.4.3.1 *Isochronous Pipe Synchronization*

When it is necessary to synchronize an isochronous data pipe to the host, the (micro) frame number (USB\_UOG\_FRINDEX register) can be used as a marker.

To cause a packet transfer to occur at a specific (micro) frame number [N], the DCD should interrupt on SOF during frame N-1. When the USB\_UOG\_FRINDEX=N-1, the DCD must write the prime bit. The device controller will prime the isochronous endpoint in (micro) frame N-1 so that the device controller will execute delivery during (micro) frame N.

**NOTE**

Priming an endpoint towards the end of (micro) frame N-1 will not guarantee delivery in (micro) frame N. The delivery may actually occur in (micro) frame N+1 if device controller does

not have enough time to complete the prime before the SOF for packet N is received.

11.4.4.6.4.3.2 Isochronous Endpoint Bus Response Matrix

The following table shows the response matrix for the Isochronous Endpoint Bus.

**Table 11-127. Isochronous Endpoint Bus Response Matrix**

	Stall	Not Primed	Primed	Underflow	Overflow
Setup	STALL	STALL	STALL	N/A	N/A
In	NULL Packet	NULL Packet	Transmit	BS Error	N/A
Out	Ignore	Ignore	Receive	N/A	Drop Packet
Ping	Ignore	Ignore	Ignore	Ignore	Ignore
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

1. BS Error = Force Bit Stuff Error

NULL Packet = Zero Length Packet

11.4.4.6.5 Managing Queue Heads

The following figure shows the End Point Queue Head.

**Figure 11-88. End Point Queue Head Diagram**

The device queue head (dQH) points to the linked list of transfer tasks, each depicted by the device Transfer Descriptor (dTDT). An area of memory pointed to by USB.ENDPOINTLISTADDR contains a group of all dQH's in a sequential list as shown in [Figure 11-88](#). The even elements in the list of dQH's are used for receive endpoints (OUT/SETUP) and the odd elements are used for transmit endpoints (IN/INTERRUPT). Device transfer descriptors are linked head to tail starting at the queue head and ending at a terminate bit. Once the dTDT has been retired, it will no longer be part of the linked list from the queue head. Therefore, software is required to track all transfer descriptors because pointers will no longer exist within the queue head once the dTDT is retired (see section [Software Link Pointers](#)).

In addition to the current and next pointers and the dTDT overlay examined in section [Operational Model For Packet Transfers](#), the dQH also contains the following parameters for the associated endpoint: Multiplier, Maximum Packet Length, Interrupt On Setup. The complete initialization of the dQH including these fields is demonstrated in the next section.

### 11.4.4.6.5.1 Queue Head Initialization

One device queue head must be initialized for each active endpoint.

To initialize a device queue head:

- Write the wMaxPacketSize field as required by the USB Chapter 9 or application specific protocol.
- Write the multiplier field to 0 for control, bulk, and interrupt endpoints. For ISO endpoints, set the multiplier to 1,2, or 3 as required bandwidth and in conjunction with the USB Chapter 9 protocol.

#### NOTE

In FS mode, the multiplier field can only be 1 for ISO endpoints.

- Write the next dTDT Terminate bit field to 1.
- Write the Active bit in the status field to 0.
- Write the Halt bit in the status field to 0.

#### NOTE

The DCD must only modify dQH if the associated endpoint is not primed and there are no outstanding dTDT's.

### 11.4.4.6.5.2 Operational Model For Setup Transfers

As discussed in section [Control Endpoint Operation Model](#), setup transfer requires special treatment by the DCD. A setup transfer does not use a dTD but instead stores the incoming data from a setup packet in an 8-byte buffer within the dQH.

Upon receiving notification of the setup packet, the DCD should handle the setup transfer as demonstrated here:

1. Copy setup buffer contents from dQH - RX to software buffer.
2. Acknowledge setup backup by writing a "1" to the corresponding bit in ENDPTSETUPSTAT.

#### NOTE

- The acknowledge must occur before continuing to process the setup packet.
  - After the acknowledge has occurred, the DCD must not attempt to access the setup buffer in the dQH - RX. Only the local software copy should be examined.
3. Check for pending data or status dTD's from previous control transfers and flush if any exist as discussed in section [Flushing/De-priming an Endpoint](#).
  4. Decode setup packet and prepare data phase [optional] and status phase transfer as required by the USB Chapter 9 or application specific protocol.

#### NOTE

It is possible for the device controller to receive setup packets before previous control transfers complete. Existing control packets in progress must be flushed and the new control packet completed.

### 11.4.4.6.6 Managing Transfers with Transfer Descriptors

#### 11.4.4.6.6.1 Software Link Pointers

It is necessary for the DCD software to maintain head and tail pointers to the for the linked list of dTDs for each respective queue head.

This is necessary because the dQH only maintains pointers to the current working dTD and the next dTD to be executed. The operations described in next section for managing dTD will assume the DCD can use reference the head and tail of the dTD linked list. The following figure shows the Software Link Pointers.

**Figure 11-89. Software Link Pointers**

**NOTE**

To conserve memory, the reserved fields at the end of the dQH can be used to store the Head & Tail pointers, but it still remains the responsibility of the DCD to maintain the pointers.

**11.4.4.6.6.2 Building a Transfer Descriptor**

Before a transfer can be executed from the linked list, a dTD must be built to describe the transfer.

Use the following procedure for building dTDs.

Allocate 8-DWord dTD block of memory aligned to 8-DWord boundaries. Example: bit address 4:0 would be equal to "00000"

Write the following fields:

1. Initialize first 7 DWords to 0.
2. Set the terminate bit to 1.
3. Fill in total bytes with transfer size.
4. Set the interrupt on complete if desired.
5. Initialize the status field with the active bit set to 1 and all remaining status bits set to 0.
6. Fill in buffer pointer page 0 and the current offset to point to the start of the data buffer.
7. Initialize buffer pointer page 1 through page 4 to be one greater than each of the previous buffer pointer.

### 11.4.4.6.3 Executing A Transfer Descriptor

To safely add a dTD, the DCD must follow this procedure which will handle the event where the device controller reaches the end of the dTD list at the same time a new dTD is being added to the end of the list.

Determine whether the link list is empty: Check DCD driver to see if pipe is empty (internal representation of linked-list should indicate if any packets are outstanding).

- Case 1: Link list is empty
  - a. Write dQH next pointer AND dQH terminate bit to 0 as a single DWord operation.
  - b. Clear active & halt bit in dQH (in case set from a previous error).
  - c. Prime endpoint by writing 1 to correct bit position in .
- Case 2: Link list is not empty
  - a. Add dTD to end of linked list.
  - b. Read correct prime bit in - if 1 DONE.
  - c. Set ATDTW bit in USBCMD register to 1.
  - d. Read correct status bit in . (store in tmp. variable for later)
  - e. Read ATDTW bit in USBCMD register.
    - If 0 goto 3.
    - If 1 continue to 6.
  - f. Write ATDTW bit in USBCMD register to 0.
  - g. If status bit read in (3) is 1 DONE.
  - h. If status bit read in (3) is 0 then Goto Case 1: Step 1.

### 11.4.4.6.4 Transfer Completion

After a dTD has been initialized and the associated endpoint primed the device controller will execute the transfer upon the host-initiated request. The DCD will be notified with a USB interrupt if the Interrupt On Complete bit was set or alternately, the DCD can poll the endpoint complete register to find when the dTD had been executed. After a dTD has been executed, DCD can check the status bits to determine success or failure.

#### NOTE

Multiple dTD can be completed in a single endpoint complete notification. After clearing the notification, DCD must search the dTD linked list and retire all dTDs that have finished (Active bit cleared).

By reading the status fields of the completed dTDs, the DCD can determine if the transfers completed successfully. Success is determined with the following combination of status bits:

- Active = 0
- Halted = 0
- Transaction Error = 0
- Data Buffer Error = 0

Should any combination other than the one shown above exist, the DCD must take proper action. Transfer failure mechanisms are indicated in the [Device Error Matrix](#).

In addition to checking the status bit the DCD must read the Transfer Bytes field to determine the actual bytes transferred. When a transfer is complete, the Total Bytes transferred is by decremented by the actual bytes transferred. For Transmit packets, a packet is only complete after the actual bytes reaches zero, but for receive packets, the host may send fewer bytes in the transfer according the USB variable length packet protocol.

### 11.4.4.6.6.5 Flushing/De-priming an Endpoint

It is necessary for the DCD to flush to de-prime one more endpoints on a USB device reset or during a broken control transfer.

There may also be application specific requirements to stop transfers in progress. The following procedure can be used by the DCD to stop a transfer in progress:

1. Write a '1' to the corresponding bit(s) in .
2. Wait until all bits in are '0'.
  - Software note: this operation may take a large amount of time depending on the USB bus activity. It is not desirable to have this wait loop within an interrupt service routine.
3. Read to ensure that for all endpoints commanded to be flushed, that the corresponding bits are now '0'. If the corresponding bits are '1' after step #2 has finished, then the flush failed as described in the following:
  - Explanation: In very rare cases, a packet is in progress to the particular endpoint when commanded flush using . A safeguard is in place to refuse the flush to ensure that the packet in progress completes successfully. The DCD may need to repeatedly flush any endpoints that fail to flush by repeating steps 1-3 until each endpoint is successfully flushed.

### 11.4.4.6.6.6 Device Error Matrix

The following table summarizes packet errors that are not automatically handled by the Device Controller.

**Table 11-128. Device Error Matrix**

Error	Direction	Packet Type	Data Buffer Error Bit	Transaction Error Bit
Overflow **	RX	Any	1	0
ISO Packet Error	RX	ISO	0	1
ISO Fulfillment Error	Both	ISO	0	1

Notice that the device controller handles all errors on Bulk/Control/Interrupt Endpoints except for a data buffer overflow. However, for ISO endpoints, errors packets are not retried and errors are tagged as indicated. The table below describes the errors.

**Table 11-129. Error Descriptions**

Error	Description
Overflow	Number of bytes received exceeded max. packet size or total buffer length. ** This error will also set the Halt bit in the dQH and if there are dTDs remaining in the linked list for the endpoint, then those will not be executed.
ISO Packet Error	CRC Error on received ISO packet. Contents not guaranteed to be correct.
ISO Fulfillment Error	Host failed to complete the number of packets defined in the dQH mult field within the given (micro)frame. For scheduled data delivery the DCD may need to readjust the data queue because a fulfillment error will cause Device Controller to cease data transfers on the pipe for one (micro)frame. During the "dead" (micro)frame, the Device Controller reports error on the pipe and primes for the following frame.

#### 11.4.4.6.7 Servicing Interrupts

The interrupt service routine must consider that there are high-frequency, low-frequency operations, and error operations and order accordingly.

##### 11.4.4.6.7.1 High-Frequency Interrupts

High frequency interrupts in particular should be handled in the order below. The most important of these is listed first because the DCD must acknowledge a setup buffer in the timeliest manner possible.

The table below describes the High frequency interrupt events.

**Table 11-130. High Frequency Interrupt Events**

Execution Order	Interrupt	Action
1a	USB Interrupt - USB.ENDPTSETUPSTATUS	Copy contents of setup buffer and acknowledge setup packet (as indicated in <a href="#">Figure 11-88</a> shows the End Point Queue Head). Process setup packet according to USB 2.0 Chapter 9 or application specific protocol.

*Table continues on the next page...*

**Table 11-130. High Frequency Interrupt Events (continued)**

1b	USB Interrupt <sup>1</sup> - USB.ENDPTCOMPLETE	Handle completion of dTD as indicated in <a href="#">Figure 11-88</a> shows the End Point Queue Head.
2	SOF Interrupt	Action as deemed necessary by application. This interrupt may not have a use in all applications.

1. It is likely that multiple interrupts to stack up on any call to the Interrupt Service Routine AND during the Interrupt Service Routine.

#### 11.4.4.6.7.2 Low-Frequency Interrupts

The low frequency interrupts can be handled in any order because they do not occur often in comparison to the high-frequency interrupts.

The table below shows the Low frequency interrupt events.

**Table 11-131. Low Frequency Interrupt Events**

Interrupt	Action
Port Change	Change software state information.
Sleep Enable (Suspend)	Change software state information. Low power handling as necessary.
Reset Received	Change software state information. Abort pending transfers.

#### 11.4.4.6.7.3 Error Interrupts

Error interrupts will be least frequent and should be placed last in the interrupt service routine.

The following table shows the error interrupt events.

**Table 11-132. Error Interrupt Events**

Interrupt	Action
USB Error Interrupt	This error is redundant because it combines USB Interrupt and an error status in the dTD. The DCD will more aptly handle packet-level errors by checking dTD status field upon receipt of USB Interrupt (w/ USB.ENDPTCOMPLETE).
System Error	Unrecoverable error. Immediate Reset of core; free transfers buffers in progress and restart the DCD.

### 11.4.5 USB Non-Core Memory Map/Register Definition

There are two kinds of registers in the USB module: USB core registers and USB non-core registers.

USB core registers are used to control USB core functions, and more independent of USB features. Each USB controller core has its own core registers.

USB non-core registers are additional to USB core registers, and more dependent on USB features. i.MX series products vary in non-core registers.

This section describes only the USB non-core registers. For detailed descriptions of USB core registers, please refer to [Register Interface](#).

### NOTE

- For reserved bits, please preserve the value when writing (read its reset value, then write this value back)
- USBNC\_USB\_" prefix in register name indicates it is a USB non-core register.

### USBNC memory map

### 11.4.5.1 USBNC\_n\_CTRL1

The USB\_n\_PHY\_CTRL1 register controls the integration specific features of the USB PHY modules. These features are not directly related to basic USB functionality, but control special features, interfacing on the USB ports, as well as power control and wake-up functionality.

Address: 30B1\_0000h base + 200h offset + (65536d × i), where i=0d to 2d

**USBNC\_n\_CTRL1 field descriptions**

Field	Description
31 WIR	Wake-up Interrupt Request This bit indicates that a wake-up interrupt request is received on the OTG1 port. This bit is cleared by disabling the wake-up interrupt (clearing bit "OWIE").  1 Wake-up Interrupt Request received 0 No wake-up interrupt request received
30 Reserved	This field is reserved.
29 WKUP_DPDM_EN	Wake-up on DPDM change enable  1 (Default) DPDM changes wake-up to be enabled, it is for device only. 0 DPDM changes wake-up to be disabled only when VBUS is 0.
28–18 Reserved	This field is reserved.
17 WKUP_VBUS_EN	Wake-up on VBUS change enable  1 Enable 0 Disable
16 WKUP_ID_EN	Wake-up on ID change enable  1 Enable 0 Disable
15 WKUP_SW	Software Wake-up  1 Force wake-up 0 Inactive
14 WKUP_SW_EN	Software Wake-up Enable  1 Enable 0 Disable
13–11 Reserved	This field is reserved. Reserved. Do not write to.
10 WIE	Wake-up Interrupt Enable This bit enables or disables the OTG1 wake-up interrupt. Disabling the interrupt also clears the Interrupt request bit. Wake-up interrupt enable should be turned off after receiving a wake-up interrupt and turned on again prior to going in suspend mode  1 Interrupt Enabled 0 Interrupt Disabled
9 PWR_POL	Power Polarity This bit should be set according to PMIC Power Pin polarity.  1 PMIC Power Pin is High active. 0 PMIC Power Pin is Low active.
8 OVER_CUR_POL	Polarity of Overcurrent The polarity of OTG1/OTG2 port overcurrent event

*Table continues on the next page...*

## USBNC\_n\_CTRL1 field descriptions (continued)

Field	Description
	1 Low active (low on this signal represents an overcurrent condition) 0 High active (high on this signal represents an overcurrent condition)
7 OVER_CUR_DIS	Disable Overcurrent Detection 1 Disables overcurrent detection 0 Enables overcurrent detection
Reserved	This field is reserved.

## 11.4.5.2 USBNC\_n\_CTRL2

The USB\_OTGx\_PHY\_CTRL2 register allows observation of the UTMI Clock Valid status along with control of selected inputs to the USB OTG PHY transceiver.

Some of these input signals may be used for USB out-of-band signaling. Customers should use caution when overriding any UTMI signals since that will interfere with normal USB data communication.

Address: 30B1\_0000h base + 204h offset + (65536d × i), where i=0d to 2d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

### USBNC\_n\_CTRL2 field descriptions

Field	Description
31 UTMI_CLK_VLD	Indicate whether PHY clock is valid. Write 1 to clear  0 UTMI clock to USB PHY is not toggling (Default) 1 UTMI clock to USB PHY has toggled several times
30–28 Reserved	This field is reserved.
27–23 Reserved	This field is reserved.  0B11110 Default
22–21 Reserved	This field is reserved. Customers should not change the value of this bit field.
20 DIG_ID_SEL	Selects whether the USB OTG ID pin function is connected to the PHY's USB_OTG*_ID pin or a GPIO pin. The ID pin state is observed on USBNC_n_PHY_STATUS[ID_DIG].  0 Use the USB_OTG*_ID pin for the USB OTG ID pin detection function(default) 1 Use the pin configured by the IOMUXC_USB_OTG*_ID_SELECT_INPUT register for the USB OTG ID pin detection function
19–16 Reserved	This field is reserved. Customers should not change the value of this bit field.
15 DMPULLDOWN_OVERRIDEEN	Enables override of control of the DM pulldown resistor instead of the state set by the USB controller.  0 USB controller enables/disables the DM pulldown resistor in the USB PHY. 1 Use the value set by the USBNC_n_CTRL2[DMPULLDOWN_OVERRIDE] bit field to enable/disable the DM pulldown resistor in the USB PHY.
14 DMPULLDOWN_OVERRIDE	Controls state of DM pulldown resistor if USBNC_n_CTRL2[DMPULLDOWN_OVERRIDEEN] is set to 1'b1.  0 DM pulldown resistor disabled 1 DM pulldown resistor enabled

Table continues on the next page...

## USBNC\_n\_CTRL2 field descriptions (continued)

Field	Description
13 DPPULLDOWN_ OVERRIDEEN	Enables override of control of the DP pulldown resistor instead of using the state set by the USB controller.  0 USB controller enables/disables the DP pulldown resistor in the USB PHY. 1 Use the value set by the USBNC_n_CTRL2[DPPULLDOWN_OVERRIDE] bit field to enable/disable the DP pulldown resistor in the USB PHY.
12 DPPULLDOWN_ OVERRIDE	Controls state of DP pulldown resistor if USBNC_n_CTRL2[DPPULLDOWN_OVERRIDEEN] is set to 1'b1.  0 DP pulldown resistor disabled 1 DP pulldown resistor enabled
11 XCVRSEL_ OVERRIDEEN	Enables override of control of the UTMI XcvrSelect signals to the USB OTG PHY instead of using the state normally set by the USB controller.  0 The state of the UTMI XcvrSelect signals to the USB PHY is set by the USB controller. 1 The state of the UTMI XcvrSelect signals to the USB PHY is set by the values in the USBNC_x_CTRL2[XCVRSEL_OVERRIDE] bit field.
10–9 XCVRSEL_ OVERRIDE	Controls the state of the UTMI XcvrSelect signals to the USB OTG PHY if the value of USBNC_x_CTRL2[XCVRSEL_OVERRIDEEN] is set to 1'b1.  See the <i>UTMI+ Specification</i> for descriptions of the functions of the XcvrSelect signals.
8 OPMODE_ OVERRIDEEN	Enables override of control of the UTMI OpMode signals to the USB OTG PHY instead of using the state normally set by the USB controller.  0 The state of the UTMI OpMode signals to the USB PHY is set by the USB controller. 1 The state of the UTMI OpMode signals to the USB PHY is set by the values in the USBNC_x_CTRL2[OPMODE_OVERRIDE] bit field.
7–6 OPMODE_ OVERRIDE	Controls the state of the UTMI XcvrSelect signals to the USB OTG PHY if the value of USBNC_x_CTRL2[OPMODE_OVERRIDEEN] is set to 1'b1.  See the <i>UTMI+ Specification</i> for descriptions of the functions of the OpMode signals.
5 TERMSEL_ OVERRIDEEN	Enables override of control of the UTMI TermSelect signal to the USB OTG PHY instead of using the state normally set by the USB controller.  0 The state of the UTMI TermSelect signal to the USB PHY is set by the USB controller. 1 The state of the UTMI TermSelect signal to the USB PHY is set by the value in the USBNC_x_CTRL2[TERMSEL_OVERRIDE] bit field.
4 TERMSEL_ OVERRIDE	Controls the state of the UTMI TermSelect signal to the USB OTG PHY if the value of USBNC_x_CTRL2[TERMSEL_OVERRIDEEN] is set to 1'b1.  See the <i>UTMI+ Specification</i> for descriptions of the function of the TermSelect signal.
3 LOWSPEED_EN	Set if AUTURESUME_EN is set and works on low speed.  0 Default
2 AUTURESUME_ EN	Auto Resume Enable  This bit field is for UTMI OTG PHY host mode only (UH core does not have this feature since HSIC PHY does not support auto resume). To set USB, it will send resume with 32 KHz clock when it detects remote wakeup from device. This feature is useful if device drives a very short remote wakeup (minimal value is 1 ms for USB2 spec) and system 24 MHz is off during suspend mode.  0 Default

Table continues on the next page...

**USBNC\_n\_CTRL2 field descriptions (continued)**

Field	Description
VBUS_SOURCE_SEL	VBUS source select used to detect a VBUS wakeup event. This bit field is for UTMI OTG PHY only (UH core and HSIC PHY have no such feature).  2'b00 vbus_valid others sess_valid

**11.4.5.3 USB OTG PHY Configuration Register 1 (USBNC\_n\_PHY\_CFG1)**

The USB\_OTGx\_PHY\_CFG1 register allows control of selected inputs to the USB OTG PHY.

Most of these signals are used for parametric tuning of the USB transceiver functions.

One signal is used to allow persistent control of the USB\_OTG1\_CHD\_B external pin.

Address: 30B1\_0000h base + 230h offset + (65536d × i), where i=0d to 1d

**USBNC\_n\_PHY\_CFG1 field descriptions**

Field	Description
31 CHRGDET_Megamix	USB_OTG1_CHD_B output control  This signal controls the state of the USB_OTG1_CHD_B external pin together with the CHRGDET (USBNC_USB_OTG1_PHY_STATUS[29] signal during periods when the SOC is fully powered.  If either CHRGDET_Megamix or CHRGDET are set to 1'b1, then USB_OTG1_CHD_B will be pulled low. If both CHRGDET_Megamix and CHRGDET are set to 1'b0, then USB_OTG1_CHD_B will be pulled high by its external open-drain pull-up resistor.

*Table continues on the next page...*

## USBNC\_n\_PHY\_CFG1 field descriptions (continued)

Field	Description
	<p><b>Note:</b> The instance of this bit field for the USB OTG2 PHY does not produce results on an external pin. The R/W register bit may still be used as a memory location to store results of Battery Charger detection tests for USB OTG2 PHY.</p> <p>0 The external state of USB_OTG1_CHD_B is only controlled by the state of the CHRGET signal</p> <p>1 The external state of USB_OTG1_CHD_B is forced low</p>
30 TXPREEMPULSESETUNE0	<p>HS Transmitter Pre-Emphasis Duration Control</p> <p>This signal controls the duration for which the HS pre-emphasis current is sourced on the the USB_OTG*_DP and USB_OTG*_DN pins. The HS Transmitter pre-emphasis duration is defined in terms of unit amounts. One unit of pre-emphasis duration is approximately 580ps and is defined as 1X pre-emphasis duration. This signal is valid only if TXPREEMPAMPTUNE (USBNC_USB_OTGx_PHY_CFG1[29:28]) is NOT set to 2'b00.</p> <p>0 2X, long pre-emphasis current duration (design default)</p> <p>1 1X, short pre-emphasis current duration</p>
29–28 TXPREEMPAMPTUNE0	<p>HS Treansmitter Pre-Emphasis Current Control</p> <p>This signal controls the amount of current sourced to the USB_OTG*_DP and USB_OTG*_DN pins after a J-to-K or K-to-J transition. The HS Transmitter pre-emphasis current is defined in terms of unit amounts. One unit amount is approximately 600uA and is defined as 1X pre-emphasis current.</p> <p>00 HS Transmitter pre-emphasis is disabled</p> <p>01 HS Transmitter pre-emphasis circuit sources 1X pre-emphasis current (design default)</p> <p>10 HS Transmitter pre-emphasis circuit sources 2X pre-emphasis current</p> <p>11 HS Transmitter pre-emphasis circuit sources 3X pre-emphasis current</p>
27–26 TXRESTUNE0	<p>USB Source Impedance Adjustment</p> <p>In some applications, there can be significant series resistance on the USB DP/DN path between the USB_OTG*_DP/USB_OTG*_DN pins tns and the USB cable. This bus adjusts the driver source impedance to compensate for that added resistance.</p> <p><b>Note:</b> Any setting other than the design default can cause HS/FS signal integrity changes along with variation across process, voltage, and temperature conditions that affect compliance with USB 2.0 specification limits.</p> <p>00 Source impedance is increased by approximately 1.5 <math>\Omega</math></p> <p>01 Design default</p> <p>10 Source impedance is decreased by approximately 2 <math>\Omega</math></p> <p>11 Source impedance is decreased by approximately 4 <math>\Omega</math></p>
25–24 TXRISETUNE0	<p>HS Transmitter Rise/Fall Time Adjustment</p> <p>This bus adjust the rise/fall times of the high-speed transmitter waveform.</p> <p>00 -10%</p> <p>01 Design default</p> <p>10 +15%</p> <p>11 +20%</p>
23–20 TXVREFTUNE0	<p>HS DC Voltage Level Adjustment</p> <p>This bus adjust the high-speed transmitter DC level voltage.</p>

### 11.4.5.4 USB OTG PHY Configuration Register 2 (USBNC\_n\_PHY\_CFG2)

The USB\_OTGx\_PHY\_CFG2 register allows control of selected inputs to the USB OTG PHY.

Most of these signals are used for configuration of VBUS detection, ADP (Attach Detection Protocol), and Battery Charging ACA (Accessory Charging Adaptor) functions.

Address: 30B1\_0000h base + 234h offset + (65536d × i), where i=0d to 1d

**USBNC\_n\_PHY\_CFG2 field descriptions**

Field	Description
31–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 DRVVBUS0	VBUS Valid Comparator Enable  This signal controls the USB OTG PHY VBUS Valid comparator which indicates whether the voltage on the USB_OTG*_VBUS pin is below the VBUS Valid threshold. The VBUS Valid threshold is nominally 4.75V on this USB PHY. The VBUS Valid threshold can be adjusted using the USBNC_OTGn_PHY_CFG1[OTGTUNE0] bit field. Status of the VBUS Valid comparator, when it is enabled, is reported on the USBNC_OTGn_PHY_STATUS[VBUS_VLD] bit.  When OTGDISABLE0 (USBNC_USB_OTGx_PHY_CFG2[10]) is set to 1'b0 and DRVVBUS0 is set to 1'b1, the Bandgap circuitry and VBUS Valid comparator are powered, even in Suspend or Sleep mode.  DRVVBUS0 should be reset to 1'b0 when the internal VBUS Valid comparator is not required, to reduce quiescent current in Suspend or Sleep mode.  0 The VBUS Valid comparator is disabled 1 The VBUS Valid comparator is enabled
15 VBUSVLDXT	External VBUS Valid Indicator

Table continues on the next page...

## USBNC\_n\_PHY\_CFG2 field descriptions (continued)

Field	Description
	<p>This signal is used if a VBUS Valid signal generated from a circuit outside the USB OTG PHY is desired.</p> <p>If the USB OTG PHY is configured for Device mode and VBUSVLDEXTSEL0 (USBNC_USB_OTGx_PHY_CFG2[14] is set to 1'b1, VBUSVLD indicated whether the VBUS signal on the USB cable is valid and enables the pull-up resistor on USB_OTG1_DP.</p> <p>This signal has no effect when the USB OTG PHY is configured for Host mode.</p> <p>0 The VBUS signal sensed outside the USB OTG PHY is not valid, and the pull-up resistor on USB_OTG*_DP is disabled</p> <p>1 The VBUS signal sensed outside the USB OTG PHY is valid, and the pull-up resistor on USB_OTG*_DP is enabled</p>
14 VBUSVLDEXTSEL0	<p>External VBUS Valid Select</p> <p>This signal selects whether the VBUSVLDEXT input (USBNC_USB_OTGx_PHY_CFG2[15]) or the internal Session Valid comparator in the USB OTG PHY is used to check if the VBUS signal on USB_OTG*_VBUS is valid and to enable the pull-up resistor on the USB_OTG*_DP pin.</p> <p>The activation of the pull-up resistor on the USB_OTG*_DP pin also depends on the state of the XCVRSEL, OPMODE, TERMSEL, DPPULLDOWN, and DMPULLDOWN signals in the UTMI bus per the UTMI+ specification.</p> <p>0 The USB OTG PHY internal Session Valid comparator is used to enable the pull-up resistor on the USB_OTG*_DP pin</p> <p>1 The VBUSVLDEXT signal is used to enable the pull-up resistor on the USB_OTG*_DP pin</p>
13 ADPPRBENB0	<p>ADP Probe Enable</p> <p>This signal determines whether the ADP (Attach Detection Protocol) Probe comparator on the USB_OTG*_VBUS pin is enabled.</p> <p>The ADP Probe threshold is &gt; 0.6V and &lt; 0.75V on this USB PHY.</p> <p>0 ADP Probe comparator is disabled</p> <p>1 ADP Probe comparator is enabled</p>
12 ADPDISCHRG0	<p>VBUS Input ADP Discharge Enable</p> <p>This signal controls discharging the USB_OTG*_VBUS pin during ADP.</p> <p>The I<sub>ADP_SINK</sub> current is &gt;1.1mA and &lt;2.0mA.</p> <p>0 Disables discharging USB_OTG*_VBUS during ADP</p> <p>1 Enables discharging USB_OTG*_VBUS during ADP</p>
11 ADPCHRG0	<p>VBUS Input ADP Charge Enable</p> <p>This signal controls charging the USB_OTG*_VBUS pin during ADP.</p> <p>The I<sub>ADP_SRC</sub> current is &gt;1.1mA and &lt;1.65mA.</p> <p>0 Disables charging USB_OTG*_VBUS during ADP</p> <p>1 Disables charging USB_OTG*_VBUS during ADP</p>
10 OTGDISABLE0	<p>OTG Block Disable</p> <p>This signal powers down the VBUS Valid comparator. It does not control power to the Session Valid comparator, ADP Probe and Sense comparators, or the ID detection circuitry.</p>

<p>5 SLEEPM0</p>	<p>Sleep Mode Assertion</p> <p>Asserting this signal places the USB OTG PHY in Sleep mode according to the USB 2.0 Link Power Management (LPM) addendum to the USB 2.0 specification. In Sleep mode, the transmitter is tri-stated and the USB OTG PHY circuits used in this SOC are powered down.</p> <p><b>Note:</b>The USB controller used in this SOC does not support LPM operation. Leave this bit set to 1'b1 for normal operation.</p> <p>0 Sleep mode</p> <p>1 Normal operating mode</p>
<p>4 ACAENB0</p>	<p>ACA USB_OTG*_ID Pin Resistance Detection Enable</p> <p>This signal enables the circuitry to detect resistance on the USB_OTG*_ID pin if the USB cable is connected to an ACA (Accessory Charger Adaptor).</p> <p>When ACAENB0 is set to 1'b1, IDPULLUP0 (USB_OTGSC[26]) is overridden and set to 1'b0 internally to the USB OTG PHY.</p> <p>The RID* results are reported in USBNC_USB_OTGx_PHY_STATUS[28:24].</p> <p>0 Disables detection of resistance on the USB_OTG*_ID pin</p> <p>1 Enables detection of resistance on the USB_OTG*_ID pin</p>
<p>3 DCDENB</p>	<p>Data Contact Detection Enable</p> <p>This signal enables current sourcing on the USB_OTG*_DP pin and pull-down resistance on the USB_OTG*_DN pin for Data Contact Detect (DCD) per the USB Battery Charging Specification revision 1.2.</p>

Table continues on the next page...

## USBNC\_n\_PHY\_CFG2 field descriptions (continued)

Field	Description
	<p><b>Note:</b> During normal USB operation of the USB OTG PHY, set this signal to 1'b0.</p> <p>0 IDP_SRC current and R<sub>DM_DWN</sub> pull-down resistance are disabled</p> <p>1 IDP_SRC current and R<sub>DM_DWN</sub> pull-down resistance are enabled</p>
2 VDATSRCENB0	<p>Battery Charging Source Select</p> <p>This signal is used to enable the VD*_SRC voltage source and ID*_SINK current sink per the USB Battery Charging Specification revision 1.2.</p> <p>Pin selection for the voltage source and the current sink are controlled by USBNC_USB_OTGx_PHY_CFG2[0].</p> <p><b>Note:</b> During normal USB operation of the USB OTG PHY, set this signal to 1'b0.</p> <p>0 VD*_SRC and ID*_SINK are disabled</p> <p>1 VD*_SRC and ID*_SINK are enabled</p>
1 VDATDETENB0	<p>Battery Charging Attach / Connect Detection Enable</p> <p>This signal is used to enable attach/connect detection per the USB Battery Charging Specification revision 1.2.</p> <p>Results are reported by using the single-ended receiver status in USBNC_USB_OTGx_PHY_STATUS[1:0].</p> <p><b>Note:</b> During normal USB operation of the USB OTG PHY, set this signal to 1'b0.</p> <p>0 IDP_SRC current source compliant to VLGC_HI connected to USB_OTG*_DP pin is disabled</p> <p>1 IDP_SRC current source compliant to VLGC_HI connected to USB_OTG*_DP pin is enabled</p>
0 CHRGSEL	<p>Battery Charging Source Select</p> <p>This signal is used to select the Battery Charging detection connections per the USB Battery Charging Specification revision 1.2. It determines which of USB_OTG*_DP / USB_OTG*_DN has the VD*_SRC voltage source and which has the ID*_SINK current sink.</p> <p>Results are reported in USBNC_USB_OTGx_PHY_STATUS[29].</p> <p><b>Note:</b> During normal USB operation of the USB OTG PHY, set this signal to 1'b0.</p> <p>0 VDP_SRC is connected to USB_OTG*_DP and IDM_SINK is connected to USB_OTG*_DN. Used for Primary Detection.</p> <p>1 VDM_SRC is connected to USB_OTG*_DN and IDP_SINK is connected to USB_OTG*_DP. Used for Secondary Detection.</p>

### 11.4.5.5 USB OTG PHY Status Register (USBNC\_n\_PHY\_STATUS)

The USB\_OTGx\_PHY\_STATUS register allows visibility of selected outputs of the USB OTG PHY.

These signals are used for some VBUS detection, ADP (Attach Detection Protocol), and Battery Charging ACA (Accessory Charging Adaptor) functions.

## Universal Serial Bus Controller (USB)

Address: 30B1\_0000h base + 23Ch offset + (65536d × i), where i=0d to 1d

## USBNC\_n\_PHY\_STATUS field descriptions

Field	Description
31 ADPSNS0	<p>ADP Sense Indicator</p> <p>This signal is output from the USB OTG PHY ADP Sense comparator and indicates whether the voltage on the USB_OTG*_VBUS pin is below the ADP sensing voltage.</p> <p>0 The voltage on USB_OTG*_VBUS is below the ADP sensing voltage 1 The voltage on USB_OTG*_VBUS is above the ADP sensing voltage</p>
30 ADPPRB0	<p>ADP Probe Indicator</p> <p>This signal is output from the USB OTG PHY ADP Probe comparator and indicates whether the voltage on the USB_OTG*_VBUS pin is below the ADP probing voltage.</p> <p>0 The voltage on USB_OTG*_VBUS is below the ADP probing voltage 1 The voltage on USB_OTG*_VBUS is above the ADP probing voltage</p>
29 CHRGDET	<p>Battery Charger Detection Output</p> <p>This signal indicates whether the voltage level on USB_OTG*_DP or USB_OTG*_DN is greater than VDAT_REF as defined in the USB Battery Charger, Revision 1.2 Specification.</p> <p>The selection of which USB data pins have the VD*_SRC and the ID*_SINK sources is controlled by register bit USBNC_USB_OTGx_CFG2[0].</p> <p>The CHRGDET register bit is only valid when USBNC_USB_OTGx_CFG2[2:1] is set to 2'b11.</p> <p>0 VD* &lt; VDAT_REF 1 VD* &gt; VDAT_REF</p>
28 RIDFLOAT0	<p>ACA USB_OTG*_ID Pin Resistance Indicator</p> <p>For USB Charger Detection, indicates whether the USB_OTG*_ID pin connected to an ACA is floating (has resistance &gt; R<sub>ID_FLOAT</sub>).</p> <p>0 ACA OTG_ID pin resistance is ≤ R<sub>ID_A</sub> (max) 1 ACA OTG_ID pin resistance is ≥ R<sub>ID_FLOAT</sub> (min)</p>
27 RIDGND0	<p>ACA USB_OTG*_ID Pin Resistance Indicator</p> <p>For USB Charger Detection, indicates whether the USB_OTG*_ID pin connected to an ACA is grounded (has resistance &lt; R<sub>ID_GND</sub>).</p> <p>0 ACA OTG_ID pin resistance is ≥ R<sub>ID_C</sub> (min) 1 ACA OTG_ID pin resistance is ≤ R<sub>ID_GND</sub> (max)</p>
26 RIDA0	<p>ACA USB_OTG*_ID Pin Resistance Indicator</p> <p>For USB Charger Detection, indicates whether the USB_OTG*_ID pin connected to an ACA is within the R<sub>ID_A</sub> range.</p> <p>0 ACA OTG_ID pin resistance is ≥ R<sub>ID_FLOAT</sub> (min) and ≤ R<sub>ID_B</sub> max 1 ACA OTG_ID pin resistance is ≥ R<sub>ID_A</sub> (min) and ≤ R<sub>ID_A</sub> max</p>
25 RIDB0	<p>ACA USB_OTG*_ID Pin Resistance Indicator</p> <p>For USB Charger Detection, indicates whether the USB_OTG*_ID pin connected to an ACA is within the R<sub>ID_B</sub> range.</p> <p>0 ACA OTG_ID pin resistance is ≥ R<sub>ID_A</sub> (min) and ≤ R<sub>ID_C</sub> max 1 ACA OTG_ID pin resistance is ≥ R<sub>ID_B</sub> (min) and ≤ R<sub>ID_B</sub> max</p>

Table continues on the next page...

**USBNC\_n\_PHY\_STATUS field descriptions (continued)**

Field	Description
24 RIDCO	<p>ACA USB_OTG*_ID Pin Resistance Indicator</p> <p>For USB Charger Detection, indicates whether the USB_OTG*_ID pin connected to an ACA is within the R<sub>ID_C</sub>) range.</p> <p>0 ACA OTG_ID pin resistance is <math>\geq R_{ID\_B}</math> (min) and <math>\leq R_{ID\_GND}</math> max                      1 ACA OTG_ID pin resistance is <math>\geq R_{ID\_C}</math> (min) and <math>\leq R_{ID\_C}</math> max</p>
23–6 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
5 HOST_ DISCONNECT	<p>Peripheral Disconnect Indicator</p> <p>This signal indicates to the USB_OTGx controller that a peripheral has been disconnected from or connected to the USB cable.</p> <p>In high-speed host operation, HOST_DISCONNECT is updated only at the end of SOF packet transmission. In FS and LS host operations, HOST_DISCONNECT is updated according to UTMI+ Specification, Section 2.2.1.10.</p> <p>This output is valid only when the USB OTG PHY and associated USB controller are configured to Host mode by setting USBNC_n_USBMODE[1:0] to 2'b11.</p> <p>0 Peripheral is connected                      1 No peripheral is connected</p>
4 ID_DIG	<p>Micro- or Mini- A/B Plug Indicator</p> <p>This signal is the output from the ID pin A/B detector, which determines whether the resistance from the USB_OTG*_ID pin to VSS is grounded (10 <math>\Omega</math> maximum for a Micro- or Mini-A plug) or floating (1 Meg<math>\Omega</math> minimum for a Micro- or Mini- B plug).</p> <p>The USB OTG PHY internal ID pin A/B detector circuit is enabled or disabled depending on the states of register bits USBNC_n_OTGSC[5] and USBNC_USB_OTGx_PHY_CFG2[4].</p> <p>Selection of whether to use the USB OTG PHY ID pin A/B detector or a GPIO pin ID detector is determined by the state of the USBNC_n_CTRL2[<b>DIG_ID_SEL</b>] bit field.</p> <p>0 The connected plug is a Micro- or Mini-A plug                      1 The connected plug is a Micro- or Mini-B plug</p>
3 VBUS_VLD	<p>VBUS Valid Indicator from USB OTG PHY</p> <p>This signal is the output from the USB OTG PHY VBUS Valid comparator and indicates whether the voltage on the USB_OTG*_VBUS pin is below the VBUS Valid threshold. The threshold is 4.75V but can be adjusted with OTGTUNE0 (USBNC_USB_PHY_CFG1[12:10]).</p> <p>The USB OTG PHY VBUS Valid comparator is enabled or disabled depending on the states of register bits USBNC_USB_OTGx_PHY_CFG2[10] and USBNC_USB_OTGx_PHY_CFG2[16].</p> <p>0 The voltage on USB_OTG*_VBUS is below the VBUS Valid threshold                      1 The voltage on USB_OTG*_VBUS is above the VBUS Valid threshold</p>
2 SESS_VLD	<p>OTG Device Session Valid Indicator from USB OTG PHY</p> <p>This signal is the output from the USB OTG PHY Session Valid comparator and indicates whether the voltage on the USB_OTG*_VBUS pin is below the OTG Device Session Valid threshold. The Session Valid threshold is <math>&gt; 0.8V</math> and <math>&lt; 2.0V</math> on this USB PHY.</p> <p>0 The voltage on USB_OTG*_VBUS is below the OTG Device Session Valid threshold                      1 The voltage on USB_OTG*_VBUS is above the OTG Device Session Valid threshold</p>

*Table continues on the next page...*

## USBNC\_n\_PHY\_STATUS field descriptions (continued)

Field	Description
LINE_STATE	<p>Line State Indicator outputs from USB OTG PHY</p> <p>These signals reflect the state of the single-ended receivers as defined by the UTMI+ Specification. In Suspend or Sleep mode, this bus is a combinatorial output (directly reflecting the current state of DN and DP, respectively).</p> <p>During normal high-speed packet transfers, the line indicates a high-speed J state.</p> <p>00 SE0 (DP low, DN low)  01 J state for high-speed and full-speed USB traffic; K state for low-speed USB traffic (DP high, DN low)  10 K state for high-speed and full-speed USB traffic; J state for low-speed USB traffic (DP low, DN high)  11 SE1 (DP high, DN high)</p>

## 11.4.5.6 USBNC\_ADP\_CFG1

Address: 30B1\_0000h base + 250h offset = 30B1\_0250h

**USBNC\_ADP\_CFG1 field descriptions**

Field	Description
31–24 Reserved	This field is reserved. Normal read/write able register  8'b0 Default
23 ADP_PRB_EN	Set to enable the ADP probe sequence  0 Default
22 ADP_PRB_INT_EN	ADP probe interrupt enable  0 Default
21 ADP_SNS_INT_EN	ADP Sense Interrupt Enable  0 Default
20 TIMER_EN	ADP Timer Test Enable  Set will start the internal 18-bit counter.  0 Default
19–18 Reserved	This field is reserved.
ADP_WAIT	Delay between 2 ADP probe, default value is about 1.5 s in 32 KHz.  18'hc000 Default

## 11.4.5.7 USBNC\_ADP\_CFG2

Address: 30B1\_0000h base + 254h offset = 30B1\_0254h

### USBNC\_ADP\_CFG2 field descriptions

Field	Description
31–24 Reserved	This field is reserved. Normal read/write able register  8'b0 Default
23–16 ADP_DISCHG_ TIME	ADP Discharge time Default value is about 2.2 ms in 32 KHz.  8'h46 Default
15–8 ADP_CHRG_ SWTIME	ADP charge time assigned by software  8'h40 Default
7 ADP_CHRG_ SWCMP	If set, HW uses ADP_CHRG_SWTIME to compare. If clear, HW compares current charge time with n-2 (see otg2 spec).

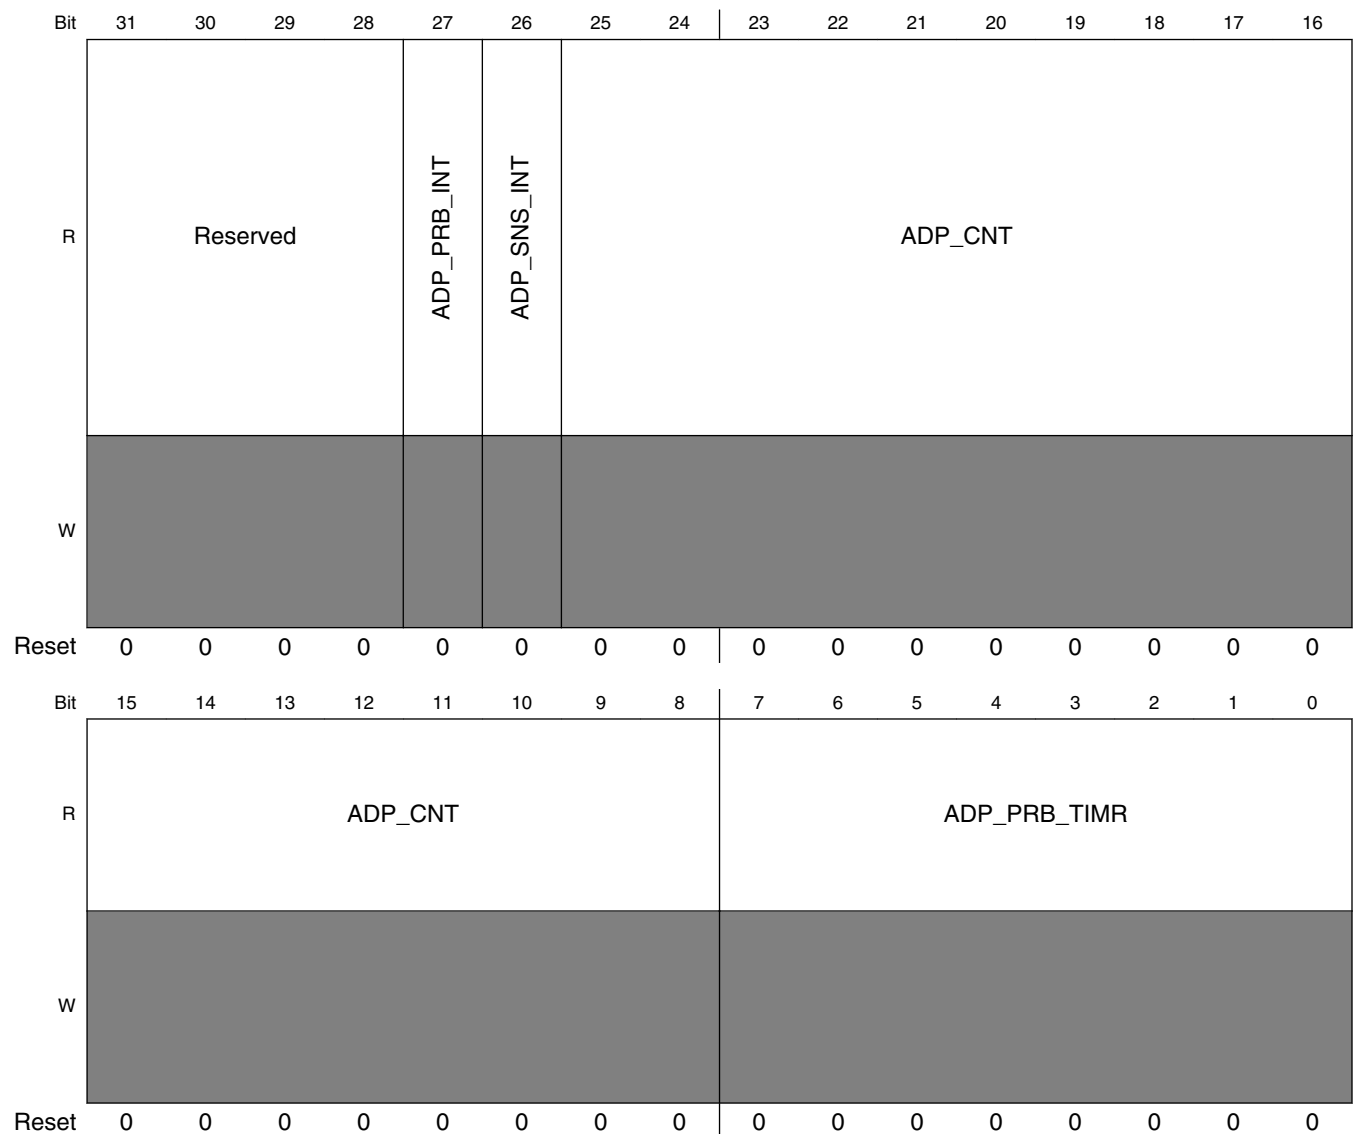

Table continues on the next page...

**USBNC\_ADP\_CFG2 field descriptions (continued)**

Field	Description
	0 Default
ADP_CHRG_DELTA	ADP charge time compare If diffence is larger than ADP_CHG_DELTA, it generates ADP_PROBE interrupt.
	7'h10 Default

**11.4.5.8 USBNC\_ADP\_STATUS**

Address: 30B1\_0000h base + 258h offset = 30B1\_0258h

### USBNC\_ADP\_STATUS field descriptions

Field	Description
31–28 Reserved	This field is reserved.
27 ADP_PRB_INT	ADP Probe Interrupt Status Set when ADP charge time exceed [ADP_CHG_MIN, ADP_CHG_MAX] cleared by CLEAR ADP_PRB_INT_EN 0 Default
26 ADP_SNS_INT	ADP Sense Interrupt Status Set when PHY detect ADP sense cleared by clear ADP_SNS_INT_EN 0 Default
25–8 ADP_CNT	ADP Internal 18-bit Counter It counts when ADP_PRB_EN or TIMER_TEST_EN is set cleared if both ADP_PRB_EN and TIMER_TEST_EN are 0, or internal state machine change internal state machine:  IDLE When ADP_PRB_EN is 0, change to DSCH when ADP_PRB_EN is set. DSCH ADP is discharging, change to CHRГ when timer reach ADP_DSCHG_TIME. CHRГ ADP is charging, change to WAIT when PHY indicate ADP_PROBE. WAIT Wait for next probe sequence. Change to DSCH when timer reach ADP_WAIT_TIME.
ADP_PRB_TIMR	ADP Probe Time It latches the internal counter when PHY indicates ADP_PROBE. 0 Default

#### 11.4.5.9 USB Host HSIC PHY Configuration Register (USBNC\_UH\_HSICPHY\_CFG1)

This register provides functional and parametric settings for the USB UH HSIC PHY.

Customers should not need to alter the settings on this register but it will be used for characterization of the USB\_H\_DATA and USB\_H\_STROBE pins.

Address: 30B1\_0000h base + 2\_0240h offset = 30B3\_0240h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
R	0						REFCLKSEL		0	REFCLKDIV							
W	1						1		0	0							
Reset	1	1	0	0	0	0	1	0	0	0	1	0	0	0	1	0	0

## Universal Serial Bus Controller (USB)

### USBNC\_UH\_HSICPHY\_CFG1 field descriptions

Field	Description
31–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–24 REFCLKSEL	Reference clock select. Leave this field set to 2'b10. Operation with other settings is undefined.
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–16 REFCLKDIV	Reference clock frequency select. This bus selects the HSIC PHY reference clock frequency. The value must remain static during normal operation.  0100100 12 MHz (Default) 0011100 15 MHz 0011010 16 MHz 0010101 19.2 MHz 0010100 20 MHz
15–12 TXSRTUNE	Driver slew rate adjustment for USB_H_DATA and USB_H_STROBE pins.  0000 -20% 0001 -10% 0011 Design default 0111 +10% 1111 +20%
11–10 TXRPDTUNE	Driver pull-down single-ended source impedance adjustment for USB_H_DATA and USB_H_STROBE pins when driving low.  00 +11% 01 +5% 10 Design default 11 -5%
9–8 TXRPUTUNE	Driver pull-up single-ended source impedance adjustment for USB_H_DATA and USB_H_STROBE pins when driving high.  00 +11% 01 +5% 10 Design default 11 -5%
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

## USBNC\_UH\_HSICPHY\_CFG1 field descriptions (continued)

Field	Description
6 TXBITSTUFFENH	<p>High-Byte Transmit Bit-Stuffing Enable</p> <p>This controller signal controls bit stuffing on DATAINH[7:0] when OPMODE[1:0] = 2'b11. For more information on the use of this setting see UTMI+ Specification Section 2.2.1.12 .</p> <p>0 Bit stuffing is disabled 1 Bit stuffing is enabled</p>
5 TXBITSTUFFEN	<p>Low-Byte Transmit Bit-Stuffing Enable</p> <p>This controller signal controls bit stuffing on DATAIN[7:0] when OPMODE[1:0] = 2'b11. For more information on the use of this setting see UTMI+ Specification Section 2.2.1.12 .</p> <p>0 Bit stuffing is disabled 1 Bit stuffing is enabled</p>
4 SLEEPM	<p>Sleep mode assertion.</p> <p>Resetting this signal laces the USB UH HSIC PHY in Sleep mode. Since the controller used for the HSB UH HSIC port does not support USB 2.0 Link Power Management (LPM) this bit field should remain at 1'b1.</p> <p>0 Sleep mode 1 Normal operating mode</p>
3 DMPULLDOWN	<p>Bus keeper resistors enable.</p> <p>If both DPPULLDOWN and DMPULLDOWN are set to 1'b1, the HSIC PHY is configured to operate as a Host. Otherwise, the HSIC PHY is configured to operate as a Device.</p> <p>Since the controller for the USB UH HSIC port only operates as a USB Host, these signals should not be reset to 1'b0 .</p> <p>0 Disable bus keeper resistors 1 Enable bus keeper resistors</p>
2 DPPULLDOWN	<p>Bus keeper resistors enable.</p> <p>If both DPPULLDOWN and DMPULLDOWN are set to 1'b1, the HSIC PHY is configured to operate as a Host. Otherwise, the HSIC PHY is configured to operate as a Device.</p> <p>Since the controller for the USB UH HSIC port only operates as a USB Host, these signals should not be reset to 1'b0 .</p> <p>0 Disable bus keeper resistors 1 Enable bus keeper resistors</p>
1 LOOPBACKENB	<p>Loopback test enable.</p> <p>This controller signal places the HSIC PHY in Loopback mode, which enables the receive and transmit logic concurrently.</p> <p><b>Note:</b> Loopback mode is for test purposes only; it cannot be used for normal operation.</p> <p>0 During data transmission, the receive logic is disabled 1 During data transmission, the receive logic is enabled</p>
0 COMMONONN	<p>This clock configuration setting should not be changed and must remain at 1'b1.</p>

**11.4.6.1 Identification register (USBx\_ID)**

The ID register identifies the USB 2.0 High-Speed core and its revision.

Address: Base address + 0h offset

**USBx\_ID field descriptions**

Field	Description
31–24 -	This field is reserved. Reserved
23–16 REVISION	Revision number of the controller core.

*Table continues on the next page...*

### USBx\_ID field descriptions (continued)

Field	Description
15–14 -	This field is reserved. Reserved
13–8 NID	Complement version of ID
7–6 -	This field is reserved. Reserved
ID	Configuration number. This number is set to 0x05 and indicates that the peripheral is USB 2.0 High-Speed core.

### 11.4.6.2 Hardware General (USBx\_HWGENERAL)

General hardware parameters as defined in System Level Issues and Core Configuration.

#### NOTE

The reset value could vary from instance to instance. Please see the detail in bit field description and ignore reset value in summary table in this case!

Address: Base address + 4h offset

Bit	31	30	29	28	27	26	25	24		23	22	21	20	19	18	17	16

**USBx\_HWTXBUF field descriptions**

Field	Description
31–24 -	This field is reserved. Reserved
23–16 TXCHANADD	TX FIFO Buffer size is: $(2^{TXCHANADD}) * 4$ Bytes. These bits are set to '08h', so buffer size is 256*4 Bytes. For the OTG controller operating in device mode, this is the FIFO buffer size per endpoint. As the OTG controller has 8 TX endpoint, there are 8 of these buffers. For the OTG controller operating in host mode, or for Host-only controller, the entire buffer memory is used as a single TX buffer. Therefore, there is only 1 of this buffer
15–8 -	This field is reserved. Reserved
TXBURST	Default burst size for memory to TX buffer transfer. This is reset value of TXPBURST bits in USB core regsiteer USB_n_BURSTSIZE. Please see <a href="#">Programmable Burst Size (USB_BURSTSIZE)</a> .

**11.4.6.6 RX Buffer Hardware Parameters (USBx\_HWRXBUF)**

Address: Base address + 14h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved																RXADD						RXBURST									
W	Reserved																Reserved						Reserved

#### USBx\_GPTIMER0LD field descriptions

Field	Description
31–24 -	This field is reserved. Reserved
GPTLD	General Purpose Timer Load Value These bit fields are loaded to GPTCNT bits when GPTRST bit is set '1b'. This value represents the time in microseconds minus 1 for the timer duration. Example: for a one millisecond timer, load 1000-1=999 or 0x0003E7. <b>NOTE:</b> Max value is 0xFFFFF or 16.777215 seconds.

### 11.4.6.8 General Purpose Timer #0 Controller (USBx\_GPTIMER0CTRL)

This register contains the control for this countdown timer and a data field can be queried to determine the running count value. This timer has granularity on 1 us and can be programmed to a little over 16 seconds. There are two counter modes which are described in the register table below. When the timer counter value transitions to zero, an interrupt could be generated if enable.

Interrupt status bit is TI0 bit in n\_USBSTS register (See [USB Status Register \(USB\\_USBSTS\)](#) ), interrupt enable bit is TIE0 bit in n\_USBINTR register. (See [Interrupt Enable Register \(USB\\_USBINTR\)](#) .)

Address: Base address + 84h offset

In repeat mode, the timer will count down to zero, generate an interrupt and automatically reload the counter value from GPTLD bits to start again.  0 One Shot Mode 1 Repeat Mode
GPTCNT	General Purpose Timer Counter.  This field is the count value of the countdown timer.

**11.4.6.11 System Bus Config (USBx\_SBUSCFG)**

Address: Base address + 90h offset

**USBx\_SBUSCFG field descriptions**

Field	Description
31–3 -	This field is reserved. Reserved
AHBBRST	AHB master interface Burst configuration  These bits control AHB master transfer type sequence (or priority).  <b>NOTE:</b> This register overrides n_BURSTSIZE register when its value is not zero.  000 Incremental burst of unspecified length only 001 INCR4 burst, then single transfer 010 INCR8 burst, INCR4 burst, then single transfer 011 INCR16 burst, INCR8 burst, INCR4 burst, then single transfer 100 Reserved, don't use 101 INCR4 burst, then incremental burst of unspecified length 110 INCR8 burst, INCR4 burst, then incremental burst of unspecified length 111 INCR16 burst, INCR8 burst, INCR4 burst, then incremental burst of unspecified length

### 11.4.6.12 Capability Registers Length (USBx\_CAPLENGTH)

The Capability Registers Length register contains the address offset to the Operational registers relative to the CAPLENGTH register.

Address: Base address + 100h offset

**USBx\_CAPLENGTH field descriptions**

Field	Description
CAPLENGTH	These bits are used as an offset to add to register base to find the beginning of the Operational Register. Default value is '40h'.

### 11.4.6.13 Host Controller Interface Version (USBx\_HCIVERSION)

This is a 2-byte register containing a BCD encoding of the EHCI revision number supported by this host controller. The most significant byte of this register represents a major revision and the least significant byte is the minor revision.

Address: Base address + 102h offset

**USBx\_HCIVERSION field descriptions**

Field	Description
HCIVERSION	Host Controller Interface Version Number Default value is '10h', which means EHCI rev1.0.

### 11.4.6.14 Host Controller Structural Parameters (USBx\_HCSPARAMS)

The following figure shows the port steering logic capabilities of Host Control Structural Parameters (n\_HCSPARAMS).

Address: Base address + 104h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved				N_TT				N_PTT				Reserved			PI

W	Reserved				Reserved				Reserved			Reserved	Reserved			
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	1

**USBx\_HCSPARAMS field descriptions**

Field	Description
31–28 -	This field is reserved. Reserved
27–24 N_TT	Number of Transaction Translators (N_TT). Default value '0000b' This field indicates the number of embedded transaction translators associated with the USB2.0 host controller. These bits would be set to '0001b' for Multi-Port Host, and '0000b' for Single-Port Host.
23–20 N_PTT	Number of Ports per Transaction Translator (N_PTT). Default value '0000b' This field indicates the number of ports assigned to each transaction translator within the USB2.0 host controller. These bits would be set to equal N_PORTS for Multi-Port Host, and '0000b' for Single-Port Host.
19–17 -	This field is reserved. Reserved
16 PI	Port Indicators (P INDICATOR) This bit indicates whether the ports support port indicator control. When set to one, the port status and control registers include a read/writeable field for controlling the state of the port indicator This bit is "1b" in all controller core.
15–12 N_CC	Number of Companion Controller (N_CC). This field indicates the number of companion controllers associated with this USB2.0 host controller. These bits are '0000b' in all controller core.  0 There is no internal Companion Controller and port-ownership hand-off is not supported. 1 There are internal companion controller(s) and port-ownership hand-offs is supported.

Table continues on the next page...

### USBx\_HCSPARAMS field descriptions (continued)

Field	Description
11–8 N_PCC	<p>Number of Ports per Companion Controller</p> <p>This field indicates the number of ports supported per internal Companion Controller. It is used to indicate the port routing configuration to the system software.</p> <p>For example, if N_PORTS has a value of 6 and N_CC has a value of 2 then N_PCC could have a value of 3. The convention is that the first N_PCC ports are assumed to be routed to companion controller 1, the next N_PCC ports to companion controller 2, etc. In the previous example, the N_PCC could have been 4, where the first 4 are routed to companion controller 1 and the last two are routed to companion controller 2. The number in this field must be consistent with N_PORTS and N_CC.</p> <p>These bits are '0000b' in all controller core.</p>
7–5 -	<p>This field is reserved.</p> <p>Reserved</p>
4 PPC	<p>Port Power Control</p> <p>This field indicates whether the host controller implementation includes port power control. A one indicates the ports have port power switches. A zero indicates the ports do not have port power switches. The value of this field affects the functionality of the Port Power field in each port status and control register</p>
N_PORTS	<p>Number of downstream ports. This field specifies the number of physical downstream ports implemented on this host controller. The value of this field determines how many port registers are addressable in the Operational Register.</p> <p>Valid values are in the range of 1h to Fh. A zero in this field is undefined.</p> <p>These bits are always set to '0001b' because all controller cores are Single-Port Host.</p>

### 11.4.6.15 Host Controller Capability Parameters (USBx\_HCCPARAMS)

This register identifies multiple mode control (time-base bit functionality), addressing capability.

Address: Base address + 108h offset

USBx\_HCCPARAMS field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
15–8 EECP	EHCI Extended Capabilities Pointer.  This field indicates the existence of a capabilities list. A value of 00h indicates no extended capabilities are implemented. A non-zero value in this register indicates the offset in PCI configuration space of the first EHCI extended capability. The pointer value must be 40h or greater if implemented to maintain the consistency of the PCI header defined for this class of device.  <b>NOTE:</b> These bits are set '00h' in all controller core.
7–4 IST	Isochronous Scheduling Threshold.  This field indicates, relative to the current position of the executing host controller, where software can reliably update the isochronous schedule. When bit [7] is zero, the value of the least significant 3 bits indicates the number of micro-frames a host controller can hold a set of isochronous data structures (one or more) before flushing the state. When bit [7] is a one, then host software assumes the host controller may cache an isochronous data structure for an entire frame.  These bits are set '00h' in all controller core.
3 -	This field is reserved. Reserved

Table continues on the next page...

**USBx\_HCCPARAMS field descriptions (continued)**

Field	Description
2 ASP	<p>Asynchronous Schedule Park Capability</p> <p>If this bit is set to a one, then the host controller supports the park feature for high-speed queue heads in the Asynchronous Schedule. The feature can be disabled or enabled and set to a specific level by using the <i>Asynchronous Schedule Park Mode Enable</i> and <i>Asynchronous Schedule Park Mode Count</i> fields in the USBCMD register.</p> <p><b>NOTE:</b> ASP bit reset value: '00b' for OTG controller core, '11b' for Host-only controller core.</p>
1 PFL	<p>Programmable Frame List Flag</p> <p>If this bit is set to zero, then the system software must use a frame list length of 1024 elements with this host controller. The USBCMD register Frame List Size field is a read-only register and must be set to zero.</p> <p>If set to a one, then the system software can specify and use a smaller frame list and configure the host controller via the USBCMD register Frame List Size field. The frame list must always be aligned on a 4K-page boundary. This requirement ensures that the frame list is always physically contiguous.</p> <p>This bit is set '1b' in all controller core.</p>
0 ADC	<p>64-bit Addressing Capability</p> <p>This bit is set '0b' in all controller core, no 64-bit addressing capability is supported.</p>

**11.4.6.16 Device Controller Interface Version (USBx\_DCIVERSION)**

This register indicates the two-byte BCD encoding of the device controller interface version number.

Address: Base address + 120h offset

**USBx\_DCIVERSION field descriptions**

Field	Description
DCIVERSION	<p>Device Controller Interface Version Number</p> <p>Default value is '01h', which means rev0.1.</p>

**11.4.6.17 Device Controller Capability Parameters (USBx\_DCCPARAMS)**

These fields describe the overall device capability of the controller.

**NOTE**

This register is only available in OTG controller core.

Address: Base address + 124h offset

Bit	31	30	29	28	27	26	25	24		23	22	21	20	19	18	17	16

W	Reserved										Reserved			Reserved				
Reset	0	0	0	0	0	0	0	1		1	0	0	0	1	0	0	0	

**USBx\_DCCPARAMS field descriptions**

Field	Description
31–9 -	This field is reserved. Reserved
8 HC	Host Capable When this bit is 1, this controller is capable of operating as an EHCI compatible USB 2.0 host controller.
7 DC	Device Capable When this bit is 1, this controller is capable of operating as a USB 2.0 device.
6–5 -	This field is reserved. Reserved
DEN	Device Endpoint Number This field indicates the number of endpoints built into the device controller. If this controller is not device capable, then this field will be zero. Valid values are 0 - 15.

### 11.4.6.18 USB Command Register (USBx\_USBCMD)

The Command Register indicates the command to be executed by the serial bus host/device controller. Writing to the register causes a command to be executed.

Address: Base address + 140h offset

**USBx\_USBCMD field descriptions**

Field	Description
31–24 -	This field is reserved. Reserved
23–16 ITC	Interrupt Threshold Control -Read/Write. The system software uses this field to set the maximum rate at which the host/device controller will issue interrupts. ITC contains the maximum interrupt interval measured in micro-frames. Valid values are shown below. Value Maximum Interrupt Interval 0x00 Immediate (no threshold) 0x01 1 micro-frame 0x02 2 micro-frames 0x04 4 micro-frames 0x08 8 micro-frames 0x10 16 micro-frames

Table continues on the next page...

## USBx\_USBCMD field descriptions (continued)

Field	Description
	0x20 32 micro-frames 0x40 64 micro-frames
15 FS_2	See also bits 3-2 Frame List Size - (Read/Write or Read Only). [host mode only] This field is Read/Write only if Programmable Frame List Flag in the HCCPARAMS registers is set to one. This field specifies the size of the frame list that controls which bits in the Frame Index Register should be used for the Frame List Current index. <b>NOTE:</b> This field is made up from USBCMD bits 15, 3 and 2. Value Meaning  000 1024 elements (4096 bytes) Default value 001 512 elements (2048 bytes) 010 256 elements (1024 bytes) 011 128 elements (512 bytes) 100 64 elements (256 bytes) 101 32 elements (128 bytes) 110 16 elements (64 bytes) 111 8 elements (32 bytes)
14 -	This field is reserved. Reserved
13 SUTW	Setup TripWire - Read/Write. [device mode only] This bit is used as a semaphore to ensure that the setup data payload of 8 bytes is extracted from a QH by the DCD without being corrupted. If the setup lockout mode is off (SLOM bit in USB core register n_USBMODE, see <a href="#">USB Device Mode (USB_USBMODE)</a> ) then there is a hazard when new setup data arrives while the DCD is copying the setup data payload from the QH for a previous setup packet. This bit is set and cleared by software.  This bit would also be cleared by hardware when a hazard detected.
12 ATDTW	Add dTD TripWire - Read/Write. [device mode only] This bit is used as a semaphore to ensure proper addition of a new dTD to an active (primed) endpoint's linked list. This bit is set and cleared by software.  This bit would also be cleared by hardware when state machine is hazard region for which adding a dTD to a primed endpoint may go unrecognized.
11 ASPE	Asynchronous Schedule Park Mode Enable - Read/Write. If the <i>Asynchronous Park Capability</i> bit in the HCCPARAMS register is a one, then this bit defaults to a 1h and is R/W. Otherwise the bit must be a zero and is RO. Software uses this bit to enable or disable Park mode. When this bit is one, Park mode is enabled. When this bit is a zero, Park mode is disabled. <b>NOTE:</b> ASPE bit reset value: '0b' for OTG controller core, '1b' for Host-only controller core.
10 -	This field is reserved. Reserved
9–8 ASP	Asynchronous Schedule Park Mode Count - Read/Write. If the <i>Asynchronous Park Capability</i> bit in the HCCPARAMS register is a one, then this field defaults to 3h and is R/W. Otherwise it defaults to zero and is Read-Only. It contains a count of the number of successive transactions the host controller is allowed to execute from a high-speed queue head on the

Table continues on the next page...

**USBx\_USBCMD field descriptions (continued)**

Field	Description
	Asynchronous schedule before continuing traversal of the Asynchronous schedule. Valid values are 1h to 3h. Software must not write a zero to this bit when <i>Park Mode Enable</i> is a one as this will result in undefined behavior.  This field is set to 3h in all controller core.
7 -	This field is reserved. Reserved
6 IAA	Interrupt on Async Advance Doorbell - Read/Write.  This bit is used as a doorbell by software to tell the host controller to issue an interrupt the next time it advances asynchronous schedule. Software must write a 1 to this bit to ring the doorbell.  When the host controller has evicted all appropriate cached schedule states, it sets the Interrupt on Async Advance status bit in the USBSTS register. If the Interrupt on Sync Advance Enable bit in the USBINTR register is one, then the host controller will assert an interrupt at the next interrupt threshold.  The host controller sets this bit to zero after it has set the Interrupt on Sync Advance status bit in the USBSTS register to one. Software should not write a one to this bit when the asynchronous schedule is inactive. Doing so will yield undefined results.  This bit is only used in host mode. Writing a one to this bit when device mode is selected will have undefined results.
5 ASE	Asynchronous Schedule Enable - Read/Write. Default 0b.  This bit controls whether the host controller skips processing the Asynchronous Schedule.  Only the host controller uses this bit.  Values Meaning  0 Do not process the Asynchronous Schedule. 1 Use the ASYNCLISTADDR register to access the Asynchronous Schedule.
4 PSE	Periodic Schedule Enable- Read/Write. Default 0b.  This bit controls whether the host controller skips processing the Periodic Schedule.  Only the host controller uses this bit.  Values Meaning  0 Do not process the Periodic Schedule 1 Use the PERIODICLISTBASE register to access the Periodic Schedule.
3-2 FS_1	See description at bit 15
1 RST	Controller Reset (RESET) - Read/Write. Software uses this bit to reset the controller. This bit is set to zero by the Host/Device Controller when the reset process is complete. Software cannot terminate the reset process early by writing a zero to this register.  Host operation mode:  When software writes a one to this bit, the Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Any transaction currently in progress on USB is immediately terminated. A USB reset is not driven on downstream ports. Software should not set this bit to a one when the HCHalted bit in the USBSTS register is a zero. Attempting to reset an actively running host controller will result in undefined behavior.  Device operation mode:

*Table continues on the next page...*

## USBx\_USBCMD field descriptions (continued)

Field	Description
	<p>When software writes a one to this bit, the Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Writing a one to this bit when the device is in the attached state is not recommended, because the effect on an attached host is undefined. In order to ensure that the device is not in an attached state before initiating a device controller reset, all primed endpoints should be flushed and the USBCMD Run/Stop bit should be set to 0.</p>
<p>0 RS</p>	<p>Run/Stop (RS) - Read/Write. Default 0b. 1=Run. 0=Stop.</p> <p>Host operation mode:</p> <p>When set to '1b', the Controller proceeds with the execution of the schedule. The Controller continues execution as long as this bit is set to a one. When this bit is set to 0, the Host Controller completes the current transaction on the USB and then halts. The HC Halted bit in the status register indicates when the Controller has finished the transaction and has entered the stopped state. Software should not write a one to this field unless the controller is in the Halted state (that is, HCHalted in the USBSTS register is a one).</p> <p>Device operation mode:</p> <p>Writing a one to this bit will cause the controller to enable a pull-up on D+ and initiate an attach event. This control bit is not directly connected to the pull-up enable, as the pull-up will become disabled upon transitioning into high-speed mode. Software should use this bit to prevent an attach event before the controller has been properly initialized. Writing a 0 to this will cause a detach event.</p>

### 11.4.6.19 USB Status Register (USBx\_USBSTS)

This register indicates various states of the Host/Device Controller and any pending interrupts. This register does not indicate status resulting from a transaction on the serial bus.

Address: Base address + 144h offset

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### USBx\_USBSTS field descriptions

Field	Description
31–26 -	This field is reserved. Reserved
25 TI1	General Purpose Timer Interrupt 1(GPTINT1)--R/WC. This bit is set when the counter in the GPTIMER1CTRL register transitions to zero, writing a one to this bit will clear it.
24 TI0	General Purpose Timer Interrupt 0(GPTINT0)--R/WC. This bit is set when the counter in the GPTIMER0CTRL register transitions to zero, writing a one to this bit clears it.
23–17 -	This field is reserved. Reserved
16 NAKI	NAK Interrupt Bit--RO. This bit is set by hardware when for a particular endpoint both the TX/RX Endpoint NAK bit and corresponding TX/RX Endpoint NAK Enable bit are set. This bit is automatically cleared by hardware when all Enabled TX/RX Endpoint NAK bits are cleared.
15 AS	Asynchronous Schedule Status - Read Only. This bit reports the current real status of the Asynchronous Schedule. When set to zero the asynchronous schedule status is disabled and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Asynchronous Schedule when software transitions the Asynchronous Schedule Enable bit in the USBCMD register. When this bit and the Asynchronous Schedule Enable bit are the same value, the Asynchronous Schedule is either enabled (1) or disabled (0). Only used in the host operation mode.
14 PS	Periodic Schedule Status - Read Only.

Table continues on the next page...

**USBx\_USBSTS field descriptions (continued)**

Field	Description
	<p>This bit reports the current real status of the Periodic Schedule. When set to zero the periodic schedule is disabled, and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Periodic Schedule when software transitions the Periodic Schedule Enable bit in the USBCMD register. When this bit and the Periodic Schedule Enable bit are the same value, the Periodic Schedule is either enabled (1) or disabled (0).</p> <p>Only used in the host operation mode.</p>
13 RCL	<p>Reclamation - Read Only.</p> <p>This is a read-only status bit used to detect an empty asynchronous schedule.</p> <p>Only used in the host operation mode.</p>
12 HCH	<p>HCHalted - Read Only.</p> <p>This bit is a zero whenever the Run/Stop bit is a one. The Controller sets this bit to one after it has stopped executing because of the Run/Stop bit being set to 0, either by software or by the Controller hardware (for example, an internal error).</p> <p>Only used in the host operation mode.</p> <p>Default value is '0b' for OTG core, and '1b' for Host1/Host2/Host3 core.</p> <p>This is because OTG core is not operating as host in default. Please see CM bit in USB_n_USBMODE register.</p> <p><b>NOTE:</b> HCH bit reset value: '0b' for OTG controller core, '1b' for Host-only controller core.</p>
11 -	<p>This field is reserved.</p> <p>Reserved</p>
10 ULPII	<p>ULPI Interrupt - R/WC.</p> <p>This bit will be set '1b' by hardware when there is an event completion in ULPI viewport.</p> <p>This bit is usable only if the controller support UPLI interface mode.</p>
9 -	<p>This field is reserved.</p> <p>Reserved</p>
8 SLI	<p>DCSuspend - R/WC.</p> <p>When a controller enters a suspend state from an active state, this bit will be set to a one. The device controller clears the bit upon exiting from a suspend state.</p> <p>Only used in device operation mode.</p>
7 SRI	<p>SOF Received - R/WC.</p> <p>When the device controller detects a Start Of (micro) Frame, this bit will be set to a one. When a SOF is extremely late, the device controller will automatically set this bit to indicate that an SOF was expected. Therefore, this bit will be set roughly every 1ms in device FS mode and every 125ms in HS mode and will be synchronized to the actual SOF that is received.</p> <p>Because the device controller is initialized to FS before connect, this bit will be set at an interval of 1ms during the prelude to connect and chirp.</p> <p>In host mode, this bit will be set every 125us and can be used by host controller driver as a time base.</p> <p>Software writes a 1 to this bit to clear it.</p>
6 URI	<p>USB Reset Received - R/WC.</p> <p>When the device controller detects a USB Reset and enters the default state, this bit will be set to a one. Software can write a 1 to this bit to clear the USB Reset Received status bit.</p> <p>Only used in device operation mode.</p>

*Table continues on the next page...*

## USBx\_USBSTS field descriptions (continued)

Field	Description
5 AAI	<p>Interrupt on Async Advance - R/WC.</p> <p>System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing a one to the Interrupt on Async Advance Doorbell bit in the n_USBCMD register. This status bit indicates the assertion of that interrupt source.</p> <p>Only used in host operation mode.</p>
4 SEI	<p>System Error- R/WC.</p> <p>This bit is will be set to '1b' when an Error response is seen to a read on the system interface.</p>
3 FRI	<p>Frame List Rollover - R/WC.</p> <p>The Host Controller sets this bit to a one when the Frame List Index rolls over from its maximum value to zero. The exact value at which the rollover occurs depends on the frame list size. For example. If the frame list size (as programmed in the Frame List Size field of the USB_n_USBCMD register) is 1024, the Frame Index Register rolls over every time FRINDEX [13] toggles. Similarly, if the size is 512, the Host Controller sets this bit to a one every time FHINDEX [12] toggles.</p> <p>Only used in host operation mode.</p>
2 PCI	<p>Port Change Detect - R/WC.</p> <p>The Host Controller sets this bit to a one when on any port a Connect Status occurs, a Port Enable/Disable Change occurs, or the Force Port Resume bit is set as the result of a J-K transition on the suspended port.</p> <p>The Device Controller sets this bit to a one when the port controller enters the full or high-speed operational state. When the port controller exits the full or high-speed operation states due to Reset or Suspend events, the notification mechanisms are the USB Reset Received bit and the DCSuspend bits respectively.</p>
1 UEI	<p>USB Error Interrupt (USBERRINT) - R/WC.</p> <p>When completion of a USB transaction results in an error condition, this bit is set by the Host/Device Controller. This bit is set along with the USBINT bit, if the TD on which the error interrupt occurred also had its interrupt on complete (IOC) bit set.</p> <p>The device controller detects resume signaling only.</p>
0 UI	<p>USB Interrupt (USBINT) - R/WC.</p> <p>This bit is set by the Host/Device Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) has an interrupt on complete (IOC) bit set.</p> <p>This bit is also set by the Host/Device Controller when a short packet is detected. A short packet is when the actual number of bytes received was less than the expected number of bytes.</p>

### 11.4.6.20 Interrupt Enable Register (USBx\_USBINTR)

The interrupts to software are enabled with this register. An interrupt is generated when a bit is set and the corresponding interrupt source is active. The USB Status register (n\_USBSTS) still shows interrupt sources even if they are disabled by the n\_USBINTR register, allowing polling of interrupt events by the software.

Address: Base address + 148h offset

**USBx\_USBINTR field descriptions**

Field	Description
31–26 -	This field is reserved. Reserved
25 TIE1	General Purpose Timer #1 Interrupt Enable When this bit is one and the TI1 bit in n_USBSTS register is a one the controller will issue an interrupt.
24 TIE0	General Purpose Timer #0 Interrupt Enable When this bit is one and the TI0 bit in n_USBSTS register is a one the controller will issue an interrupt.
23–20 -	This field is reserved. Reserved
19 UPIE	USB Host Periodic Interrupt Enable

Table continues on the next page...

## USBx\_USBINTR field descriptions (continued)

Field	Description
	When this bit is one, and the UPI bit in the n_USBSTS register is one, host controller will issue an interrupt at the next interrupt threshold.
18 UAIE	USB Host Asynchronous Interrupt Enable When this bit is one, and the UAI bit in the n_USBSTS register is one, host controller will issue an interrupt at the next interrupt threshold.
17 -	This field is reserved. Reserved
16 NAKE	NAK Interrupt Enable When this bit is one and the NAKI bit in n_USBSTS register is a one the controller will issue an interrupt.
15–11 -	These bits are reserved and should be set to zero.
10 ULPIE	ULPI Interrupt Enable When this bit is one and the UPLI bit in n_USBSTS register is a one the controller will issue an interrupt. This bit is usable only if the controller support UPLI interface mode.
9 -	This field is reserved. Reserved
8 SLE	Sleep Interrupt Enable When this bit is one and the SLI bit in n_n_USBSTS register is a one the controller will issue an interrupt. Only used in device operation mode.
7 SRE	SOF Received Interrupt Enable When this bit is one and the SRI bit in n_USBSTS register is a one the controller will issue an interrupt.
6 URE	USB Reset Interrupt Enable When this bit is one and the URI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in device operation mode.
5 AAE	Async Advance Interrupt Enable When this bit is one and the AAI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in host operation mode.
4 SEE	System Error Interrupt Enable When this bit is one and the SEI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in host operation mode.
3 FRE	Frame List Rollover Interrupt Enable When this bit is one and the FRI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in host operation mode.
2 PCE	Port Change Detect Interrupt Enable When this bit is one and the PCI bit in n_USBSTS register is a one the controller will issue an interrupt.
1 UEE	USB Error Interrupt Enable When this bit is one and the UEI bit in n_USBSTS register is a one the controller will issue an interrupt.
0 UE	USB Interrupt Enable When this bit is one and the UI bit in n_USBSTS register is a one the controller will issue an interrupt.

### 11.4.6.21 USB Frame Index (USBx\_FRINDEX)

This register is used by the host controller to index the periodic frame list. The register updates every 125 microseconds (once each micro-frame). Bits [N: 3] are used to select a particular entry in the Periodic Frame List during periodic schedule execution. The number of bits used for the index depends on the size of the frame list as set by system software in the Frame List Size field in the n\_USBCMD register.

This register must be written as a DWord. Byte writes produce undefined results. This register cannot be written unless the Host Controller is in the 'Halted' state as indicated by the HCHalted bit. A write to this register while the Run/Stop hit is set to a one produces undefined results. Writes to this register also affect the SOF value.

In device mode this register is read only and, the device controller updates the FRINDEX [13:3] register from the frame number indicated by the SOF marker. Whenever a SOF is received by the USB bus, FRINDEX [13:3] will be checked against the SOF marker. If FRINDEX [13:3] is different from the SOF marker, FRINDEX [13:3] will be set to the SOF value and FRINDEX [2:0] will be set to zero (that is, SOF for 1 ms frame). If FRINDEX [13:3] is equal to the SOF value, FRINDEX [2:0] will be increment (that is, SOF for 125 us micro-frame.).

Address: Base address + 14Ch offset

#### USBx\_FRINDEX field descriptions

Field	Description
31-14 -	This field is reserved. Reserved
FRINDEX	<p>Frame Index.</p> <p>The value, in this register, increments at the end of each time frame (micro-frame). Bits [N: 3] are used for the Frame List current index. This means that each location of the frame list is accessed 8 times (frames or micro-frames) before moving to the next index.</p> <p>The following illustrates values of N based on the value of the Frame List Size field in the USBCMD register, when used in host mode.</p> <p>USBCMD [Frame List Size] Number Elements N</p> <p>In device mode the value is the current frame number of the last frame transmitted. It is not used as an index.</p> <p>In either mode bits 2:0 indicate the current microframe.</p> <p>000 (1024) 12 001 (512) 11</p>

### 11.4.6.22 Frame List Base Address (USBx\_PERIODICLISTBASE)

Host Controller only

This 32-bit register contains the beginning address of the Periodic Frame List in the system memory. HCD loads this register prior to starting the schedule execution by the Host Controller. The memory structure referenced by this physical memory pointer is assumed to be 4-Kbyte aligned. The contents of this register are combined with the Frame Index Register (USB\_n\_FRINDEX) to enable the Host Controller to step through the Periodic Frame List in sequence.

Address: Base address + 154h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### USBx\_PERIODICLISTBASE field descriptions

Field	Description
31–12 BASEADR	Base Address (Low). These bits correspond to memory address signals [31:12], respectively. Only used by the host controller.
-	This field is reserved. Reserved

### 11.4.6.23 Device Address (USBx\_DEVICEADDR)

Device Controller only

The upper seven bits of this register represent the device address. After any controller reset or a USB reset, the device address is set to the default address (0). The default address will match all incoming addresses. Software shall reprogram the address after receiving a SET\_ADDRESS descriptor.

## Universal Serial Bus Controller (USB)

Address: Base address + 154h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

### USBx\_DEVICEADDR field descriptions

Field	Description
31–25 USBADR	Device Address. These bits correspond to the USB device address
24 USBADRA	Device Address Advance. Default=0. When this bit is '0', any writes to USBADR are instantaneous. When this bit is written to a '1' at the same time or before USBADR is written, the write to the USBADR field is staged and held in a hidden register. After an IN occurs on endpoint 0 and is ACKed, USBADR will be loaded from the holding register. Hardware will automatically clear this bit on the following conditions: 1) IN is ACKed to endpoint 0. (USBADR is updated from staging register). 2) OUT/SETUP occur to endpoint 0. (USBADR is not updated). 3) Device Reset occurs (USBADR is reset to 0).  <b>NOTE:</b> After the status phase of the SET_ADDRESS descriptor, the DCD has 2 ms to program the USBADR field. This mechanism will ensure this specification is met when the DCD can not write of the device address within 2ms from the SET_ADDRESS status phase. If the DCD writes the USBADR with USBADRA=1 after the SET_ADDRESS data phase (before the prime of the status phase), the USBADR will be programmed instantly at the correct time and meet the 2ms USB requirement.
-	This field is reserved. Reserved

### 11.4.6.24 Next Asynch. Address (USBx\_ASYNCLISTADDR)

Host Controller only

This 32-bit register contains the address of the next asynchronous queue head to be executed by the host. Bits [4:0] of this register cannot be modified by the system software and will always return a zero when read.

Address: Base address + 158h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### USBx\_BURSTSIZE field descriptions

Field	Description
31–17 -	This field is reserved. Reserved
16–8 TXPBURST	Programmable TX Burst Size. Default value is determined by TXBURST bits in n_HWTXBUF. This register represents the maximum length of a the burst in 32-bit words while moving data from system memory to the USB bus.
RXPBURST	Programmable RX Burst Size. Default value is determined by TXBURST bits in n_HWRXBUF. This register represents the maximum length of a the burst in 32-bit words while moving data from the USB bus to system memory.

### 11.4.6.27 TX FIFO Fill Tuning (USBx\_TXFILLTUNING)

The fields in this register control performance tuning associated with how the host controller posts data to the TX latency FIFO before moving the data onto the USB bus. The specific areas of performance include the how much data to post into the FIFO and an estimate for how long that operation should take in the target system.

Definitions:

$T_0$  = Standard packet overhead

$T_1$  = Time to send data payload

$T_{ff}$  = Time to fetch packet into TX FIFO up to specified level.

$T_s$  = Total Packet Flight Time (send-only) packet

$T_s = T_0 + T_1$

$T_p$  = Total Packet Time (fetch and send) packet

$T_p = T_{ff} + T_0 + T_1$

Upon discovery of a transmit (OUT/SETUP) packet in the data structures, host controller checks to ensure  $T_p$  remains before the end of the [micro]frame. If so it proceeds to pre-fill the TX FIFO. If at anytime during the pre-fill operation the time remaining the [micro]frame is  $< T_s$  then the packet attempt ceases and the packet is tried at a later time. Although this is not an error condition and the host controller will eventually recover, a

mark will be made the scheduler health counter to note the occurrence of a "back-off" event. When a back-off event is detected, the partial packet fetched may need to be discarded from the latency buffer to make room for periodic traffic that will begin after the next SOF. Too many back-off events can waste bandwidth and power on the system bus and thus should be minimized (not necessarily eliminated). Back-offs can be minimized with use of the `n_TSCHEALTH` ( $T_{ff}$ ) described below.

### NOTE

The reset value could vary from instance to instance. Please see the detail in bit field description and ignore reset value in summary table in this case!

Address: Base address + 164h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved										TXFIFOTHRES						Reserved			TXSCHHEALTH				TXSCHOH								
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1	0	0	0

### USBx\_TXFILLTUNING field descriptions

Field	Description
31–22 -	This field is reserved. Reserved
21–16 TXFIFOTHRES	FIFO Burst Threshold. (Read/Write) This register controls the number of data bursts that are posted to the TX latency FIFO in host mode before the packet begins on to the bus. The minimum value is 2 and this value should be as low as possible to maximize USB performance. A higher value can be used in systems with unpredictable latency and/or insufficient bandwidth where the FIFO may underrun because the data transferred from the latency FIFO to USB occurs before it can be replenished from system memory. This value is ignored if the Stream Disable bit in USB_n_USBMODE register is set. Default value is '00h' for OTG controller core, and '02h' for Host-only controller core.
15–13 -	This field is reserved. Reserved
12–8 TXSCHHEALTH	Scheduler Health Counter. (Read/Write To Clear) This register increments when the host controller fails to fill the TX latency FIFO to the level programmed by TXFIFOTHRES before running out of time to send the packet before the next Start-Of-Frame. This health counter measures the number of times this occurs to provide feedback to selecting a proper TXSCHOH. Writing to this register will clear the counter and this counter will max. at 31. Default value is '08h' for OTG controller core, and '00h' for Host-only controller core.
TXSCHOH	Scheduler Overhead. (Read/Write) [Default = 0] This register adds an additional fixed offset to the schedule time estimator described above as $T_{ff}$ . As an approximation, the value chosen for this register should limit the number of back-off events captured in the TXSCHHEALTH to less than 10 per second in a highly utilized bus. Choosing a value that is too high for this register is not desired as it can needlessly reduce USB utilization. The time unit represented in this register is 1.267us when a device is connected in High-Speed Mode. The time unit represented in this register is 6.333us when a device is connected in Low/Full Speed Mode. Default value is '08h' for OTG controller core, and '00h' for Host-only controller core.

### 11.4.6.28 Endpoint NAK (USBx\_ENDPTNAK)

Address: Base address + 178h offset

#### USBx\_ENDPTNAK field descriptions

Field	Description
31–24 -	This field is reserved. Reserved
23–16 EPTN	TX Endpoint NAK - R/W. Each TX endpoint has 1 bit in this field. The bit is set when the device sends a NAK handshake on a received IN token for the corresponding endpoint. Bit [N] - Endpoint #[N], N is 0-7
15–8 -	This field is reserved. Reserved
EPRN	RX Endpoint NAK - R/W. Each RX endpoint has 1 bit in this field. The bit is set when the device sends a NAK handshake on a received OUT or PING token for the corresponding endpoint. Bit [N] - Endpoint #[N], N is 0-7

### 11.4.6.29 Endpoint NAK Enable (USBx\_ENDPTNAKEN)

Address: Base address + 17Ch offset

#### USBx\_ENDPTNAKEN field descriptions

Field	Description
31–24 -	This field is reserved. Reserved
23–16 EPTNE	TX Endpoint NAK Enable - R/W. Each bit is an enable bit for the corresponding TX Endpoint NAK bit. If this bit is set and the corresponding TX Endpoint NAK bit is set, the NAK Interrupt bit is set. Bit [N] - Endpoint #[N], N is 0-7
15–8 -	This field is reserved. Reserved
EPRNE	RX Endpoint NAK Enable - R/W.

Table continues on the next page...

### USBx\_ENDPTNAKEN field descriptions (continued)

Field	Description
	Each bit is an enable bit for the corresponding RX Endpoint NAK bit. If this bit is set and the corresponding RX Endpoint NAK bit is set, the NAK Interrupt bit is set. Bit [N] - Endpoint #[N], N is 0-7

### 11.4.6.30 Configure Flag Register (USBx\_CONFIGFLAG)

Address: Base address + 180h offset

### USBx\_CONFIGFLAG field descriptions

Field	Description
31–1 -	This field is reserved. Reserved
0 CF	Configure Flag Host software sets this bit as the last action in its process of configuring the Host Controller. This bit controls the default port-routing control logic.  0 Port routing control logic default-routes each port to an implementation dependent classic host controller. 1 Port routing control logic default-routes all ports to this host controller.

### 11.4.6.31 Port Status & Control (USBx\_PORTSC1)

Host Controller

A host controller could implement one to eight port status and control registers. The number is determined by N\_PORTS bits in HWSPARAMs register (please see [Host Controller Structural Parameters \(USB\\_HCSPARAMS\)](#) ). Software could read this parameter register to determine how many ports need service.

All controller cores on this product are Single-Port, so there is only one port status and control register for each controller core.

## Universal Serial Bus Controller (USB)

This register is only reset by power on reset or controller core reset. The initial conditions of a port are:

- No device connected
- Port disabled

If the port supports power control, this state remains until port power is supplied (by software).

### Device Controller

A controller operating in device mode has only port register one (PORTSC1) and it does not support power control in that mode. Port control in device mode is only used for status port reset, suspend, and current connect status. It is also used to initiate test mode or force signaling and allows software to put the PHY into low power suspend mode and disable the PHY clock.

**USBx\_PORTSC1 field descriptions (continued)**

Field	Description
23 PHCD	<p>PHY Low Power Suspend - Clock Disable (PLPSCD) - Read/Write. Default = 0b.</p> <p>When this bit is set to '1b', the PHY clock is disabled. Reading this bit will indicate the status of the PHY clock.</p> <p><b>NOTE:</b> The PHY clock cannot be disabled if it is being used as the system clock.</p> <p>In device mode, The PHY can be put into Low Power Suspend when the device is not running (USBCMD Run/Stop=0b) or the host has signalled suspend (PORTSC1 SUSPEND=1b). PHY Low power suspend will be cleared automatically when the host initials resume. Before forcing a resume from the device, the device controller driver must clear this bit.</p> <p>In host mode, the PHY can be put into Low Power Suspend when the downstream device has been put into suspend mode or when no downstream device is connected. Low power suspend is completely under the control of software.</p> <p>1 Disable PHY clock 0 Enable PHY clock</p>
22 WKOC	<p>Wake on Over-current Enable (WKOC_E) - Read/Write. Default = 0b.</p> <p>Writing this bit to a one enables the port to be sensitive to over-current conditions as wake-up events.</p> <p>This field is zero if <i>Port Power</i>(Port Status &amp; Control (USB_PORTSC1)) is zero.</p>
21 WKDC	<p>Wake on Disconnect Enable (WKDSCNNT_E) - Read/Write. Default=0b. Writing this bit to a one enables the port to be sensitive to device disconnects as wake-up events.</p> <p>This field is zero if <i>Port Power</i>(Port Status &amp; Control (USB_PORTSC1)) is zero or in device mode.</p>
20 WKN	<p>Wake on Connect Enable (WKNNT_E) - Read/Write. Default=0b.</p> <p>Writing this bit to a one enables the port to be sensitive to device connects as wake-up events.</p> <p>This field is zero if <i>Port Power</i>(Port Status &amp; Control (USB_PORTSC1)) is zero or in device mode.</p>
19–16 PTC	<p>Port Test Control - Read/Write. Default = 0000b.</p> <p>Refer to <a href="#">Port Test Mode</a> for the operational model for using these test modes and the USB Specification Revision 2.0, Chapter 7 for details on each test mode.</p> <p>The FORCE_ENABLE_FS and FORCE_ENABLE_LS are extensions to the test mode support specified in the EHCI specification. Writing the PTC field to any of the FORCE_ENABLE_{HS/FS/LS} values will force the port into the connected and enabled state at the selected speed. Writing the PTC field back to TEST_MODE_DISABLE will allow the port state machines to progress normally from that point.</p> <p><b>NOTE:</b> <i>Low speed operations are not supported as a peripheral device.</i></p> <p>Any other value than zero indicates that the port is operating in test mode.</p> <p>Value Specific Test</p> <p>0000 TEST_MODE_DISABLE 0001 J_STATE 0010 K_STATE 0011 SE0 (host) / NAK (device) 0100 Packet 0101 FORCE_ENABLE_HS 0110 FORCE_ENABLE_FS 0111 FORCE_ENABLE_LS 1000-1111 Reserved</p>

Table continues on the next page...

## USBx\_PORTSC1 field descriptions (continued)

Field	Description
15–14 PIC	<p>Port Indicator Control - Read/Write. Default = Ob.</p> <p>Writing to this field has no effect if the P_INDICATOR bit in the HCSPARAMS register is a zero.</p> <p>Refer to the USB Specification Revision 2.0 for a description on how these bits are to be used.</p> <p>This field is zero if <i>Port Power</i> is zero.</p> <p>Bit Value Meaning</p> <p>00 Port indicators are off 01 Amber 10 Green 11 Undefined</p>
13 PO	<p>Port Owner-Read/Write. Default = 0.</p> <p>This bit unconditionally goes to a 0 when the configured bit in the CONFIGFLAG register makes a 0 to 1 transition. This bit unconditionally goes to 1 whenever the Configured bit is zero. System software uses this field to release ownership of the port to a selected host controller (in the event that the attached device is not a high-speed device). Software writes a one to this bit when the attached device is not a high-speed device. A one in this bit means that an internal companion controller owns and controls the port.</p> <p>Port owner handoff is not supported in all controller cores, therefore this bit will always be 0.</p>
12 PP	<p>Port Power (PP)-Read/Write or Read Only.</p> <p>The function of this bit depends on the value of the Port Power Switching (PPC) field in the HCSPARAMS register. The behavior is as follows:</p> <p>PPC</p> <p>PP Operation</p> <p>0</p> <p>1b <i>Read Only</i> - Host controller does not have port power control switches. Each port is hard-wired to power.</p> <p>1</p> <p>1b/0b - <i>Read/Write</i>. Host/OTG controller requires port power control switches. This bit represents the current setting of the switch (0=off, 1=on). When power is not available on a port (that is, PP equals a 0), the port is non-functional and will not report attaches, detaches, etc.</p> <p>When an over-current condition is detected on a powered port and PPC is a one, the PP bit in each affected port may be transitional by the host controller driver from a one to a zero (removing power from the port).</p> <p>This feature is implemented in all controller cores (PPC = 1).</p>
11–10 LS	<p>Line Status-Read Only. These bits reflect the current logical levels of the D+ (bit 11) and D- (bit 10) signal lines.</p> <p>In host mode, the use of linestate by the host controller driver is not necessary (unlike EHCI), because the port controller state machine and the port routing manage the connection of LS and FS.</p> <p>In device mode, the use of linestate by the device controller driver is not necessary.</p> <p>The encoding of the bits are:</p> <p>Bits [11:10] Meaning</p> <p>00 SE0 10 J-state</p>

Table continues on the next page...

**USBx\_PORTSC1 field descriptions (continued)**

Field	Description
	01 K-state 11 Undefined
9 HSP	High-Speed Port - Read Only. Default = 0b. When the bit is one, the host/device connected to the port is in high-speed mode and if set to zero, the host/device connected to the port is not in a high-speed mode. <b>NOTE:</b> HSP is redundant with PSPD(bit 27, 26) but remained for compatibility.
8 PR	Port Reset - Read/Write or Read Only. Default = 0b. In Host Mode: Read/Write. 1=Port is in Reset. 0=Port is not in Reset. Default 0. When software writes a one to this bit the bus-reset sequence as defined in the USB Specification Revision 2.0 is started. <i>This bit will automatically change to zero after the reset sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the reset duration is timed in the driver.</i> In Device Mode: This bit is a read only status bit. Device reset from the USB bus is also indicated in the USBSTS register. This field is zero if <i>Port Power</i> ( <a href="#">Port Status &amp; Control (USB_PORTSC1)</a> ) is zero.
7 SUSP	Suspend - Read/Write or Read Only. Default = 0b. 1=Port in suspend state. 0=Port not in suspend state. In Host Mode: Read/Write. Port Enabled Bit and Suspend bit of this register define the port states as follows: Bits [Port Enabled, Suspend] Port State 0x Disable 10 Enable 11 Suspend When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction if a transaction was in progress when this bit was written to 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB. The host controller will unconditionally set this bit to zero when software sets the <i>Force Port Resume</i> bit to zero. The host controller ignores a write of zero to this bit. If host software sets this bit to a one when the port is not enabled (that is, <i>Port enabled</i> bit is a zero) the results are undefined. This field is zero if <i>Port Power</i> ( <a href="#">Port Status &amp; Control (USB_PORTSC1)</a> ) is zero in host mode. In Device Mode: Read Only. In device mode this bit is a read only status bit.
6 FPR	Force Port Resume -Read/Write. 1= Resume detected/driven on port. 0=No resume (K-state) detected/driven on port. Default = 0. In Host Mode: Software sets this bit to one to drive resume signaling. The Host Controller sets this bit to one if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the <i>Port Change Detect</i> bit in the USBSTS register is also set to one. <i>This bit</i>

*Table continues on the next page...*

## USBx\_PORTSC1 field descriptions (continued)

Field	Description
	<p>will automatically change to zero after the resume sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the resume duration is timed in the driver.</p> <p>Note that when the Host controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. This bit will remain a one until the port has switched to the high-speed idle. Writing a zero has no effect because the port controller will time the resume operation, clear the bit the port control state switches to HS or FS idle.</p> <p>This field is zero if <i>Port Power</i>(<a href="#">Port Status &amp; Control (USB_PORTSC1)</a>) is zero in host mode.</p> <p>This bit is not-EHCI compatible.</p> <p>In Device mode:</p> <p>After the device has been in Suspend State for 5ms or more, software must set this bit to one to drive resume signaling before clearing. The Device Controller will set this bit to one if a J-to-K transition is detected while the port is in the Suspend state. The bit will be cleared when the device returns to normal operation. Also, when this bit will be cleared because a K-to-J transition detected, the <i>Port Change Detect</i> bit in the USBSTS register is also set to one.</p>
5 OCC	<p>Over-current Change-R/WC. Default=0.</p> <p>This bit is set '1b' by hardware when there is a change to Over-current Active. Software can clear this bit by writing a one to this bit position.</p>
4 OCA	<p>Over-current Active-Read Only. Default 0.</p> <p>This bit will automatically transition from one to zero when the over current condition is removed.</p> <p>1 This port currently has an over-current condition 0 This port does not have an over-current condition.</p>
3 PEC	<p>Port Enable/Disable Change-R/WC. 1=Port enabled/disabled status has changed. 0=No change. Default = 0.</p> <p>In Host Mode:</p> <p>For the root hub, this bit is set to a one only when a port is disabled due to disconnect on the port or due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification). Software clears this by writing a one to it.</p> <p>This field is zero if <i>Port Power</i>(<a href="#">Port Status &amp; Control (USB_PORTSC1)</a>) is zero.</p> <p>In Device mode:</p> <p>The device port is always enabled, so this bit is always '0b'.</p>
2 PE	<p>Port Enabled/Disabled-Read/Write. 1=Enable. 0=Disable. Default 0.</p> <p>In Host Mode:</p> <p>Ports can only be enabled by the host controller as a part of the reset and enable. Software cannot enable a port by writing a one to this field. Ports can be disabled by either a fault condition (disconnect event or other fault condition) or by the host software. Note that the bit status does not change until the port state actually changes. There may be a delay in disabling or enabling a port due to other host controller and bus events.</p> <p>When the port is disabled, (0b) downstream propagation of data is blocked except for reset.</p> <p>This field is zero if <i>Port Power</i>(<a href="#">Port Status &amp; Control (USB_PORTSC1)</a>) is zero in host mode.</p> <p>In Device Mode:</p> <p>The device port is always enabled, so this bit is always '1b'.</p>

Table continues on the next page...

**USBx\_PORTSC1 field descriptions (continued)**

Field	Description
1 CSC	<p>Connect Status Change-R/WC. 1 =Change in Current Connect Status. 0=No change. Default 0.</p> <p>In Host Mode:</p> <p>Indicates a change has occurred in the port's Current Connect Status. The host/device controller sets this bit for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, the insertion status changes twice before system software has cleared the changed condition, hub hardware will be 'setting' an already-set bit (that is, the bit will remain set). Software clears this bit by writing a one to it.</p> <p>This field is zero if <i>Port Power</i>(<a href="#">Port Status &amp; Control (USB_PORTSC1)</a>) is zero in host mode.</p> <p>In Device Mode:</p> <p>This bit is undefined in device controller mode.</p>
0 CCS	<p>Current Connect Status-Read Only.</p> <p>In Host Mode:</p> <p>1=Device is present on port. 0=No device is present. Default = 0. This value reflects the current state of the port, and may not correspond directly to the event that caused the <i>Connect Status Change</i> bit (Bit 1) to be set.</p> <p>This field is zero if <i>Port Power</i>(<a href="#">Port Status &amp; Control (USB_PORTSC1)</a>) is zero in host mode.</p> <p>In Device Mode:</p> <p>1=Attached. 0=Not Attached. Default=0. A one indicates that the device successfully attached and is operating in either high speed or full speed as indicated by the High Speed Port bit in this register. A zero indicates that the device did not attach successfully or was forcibly disconnected by the software writing a zero to the Run bit in the USBCMD register. It does not state the device being disconnected or suspended.</p>

**11.4.6.32 On-The-Go Status & control (USBx\_OTGSC)**

This register is available only in OTG controller core. It has four sections:

- OTG Interrupt enables (Read/Write)
- OTG Interrupt status (Read/Write to Clear)
- OTG Status inputs (Read Only)
- OTG Controls (Read/Write)

The status inputs are debounced using a 1 ms time constant. Values on the status inputs that do not persist for more than 1 ms does not cause an update of the status input register, or cause an OTG interrupt.

See also [USB Device Mode \(USB\\_USBMODE\)](#) register.

Address: Base address + 1A4h offset

**USBx\_OTGSC field descriptions**

Field	Description
31 -	This field is reserved. Reserved
30 DPIE	Data Pulse Interrupt Enable
29 EN_1MS	1 millisecond timer Interrupt Enable - Read/Write
28 BSEIE	B Session End Interrupt Enable - Read/Write. Setting this bit enables the B session end interrupt.
27 BSVIE	B Session Valid Interrupt Enable - Read/Write. Setting this bit enables the B session valid interrupt.
26 ASVIE	A Session Valid Interrupt Enable - Read/Write. Setting this bit enables the A session valid interrupt.
25 AVVIE	A VBus Valid Interrupt Enable - Read/Write. Setting this bit enables the A VBus valid interrupt.
24 IDIE	USB ID Interrupt Enable - Read/Write. Setting this bit enables the USB ID interrupt.
23 -	This field is reserved. Reserved
22 DPIS	Data Pulse Interrupt Status - Read/Write to Clear. This bit is set when data bus pulsing occurs on DP or DM. Data bus pulsing is only detected when USBMODE.CM = Host (11) and PORTSC1(0)[PP] = 0. Software must write a one to clear this bit.
21 STATUS_1MS	1 millisecond timer Interrupt Status - Read/Write to Clear. This bit is set once every millisecond. Software must write a one to clear this bit.
20 BSEIS	B Session End Interrupt Status - Read/Write to Clear. This bit is set when VBus has fallen below the B session end threshold. Software must write a one to clear this bit.
19 BSVIS	B Session Valid Interrupt Status - Read/Write to Clear. This bit is set when VBus has either risen above or fallen below the B session valid threshold. Software must write a one to clear this bit.
18 ASVIS	A Session Valid Interrupt Status - Read/Write to Clear. This bit is set when VBus has either risen above or fallen below the A session valid threshold. Software must write a one to clear this bit.
17 AVVIS	A VBus Valid Interrupt Status - Read/Write to Clear. This bit is set when VBus has either risen above or fallen below the VBus valid threshold on an A device. Software must write a one to clear this bit.
16 IDIS	USB ID Interrupt Status - Read/Write. This bit is set when a change on the ID input has been detected. Software must write a one to clear this bit.

*Table continues on the next page...*

## USBx\_OTGSC field descriptions (continued)

Field	Description
15 -	This field is reserved. Reserved
14 DPS	Data Bus Pulsing Status - Read Only. A '1' indicates data bus pulsing is being detected on the port.
13 TOG_1MS	1 millisecond timer toggle - Read Only. This bit toggles once per millisecond.
12 BSE	B Session End - Read Only. Indicates VBus is below the B session end threshold.
11 BSV	B Session Valid - Read Only. Indicates VBus is above the B session valid threshold.
10 ASV	A Session Valid - Read Only. Indicates VBus is above the A session valid threshold.
9 AVV	A VBus Valid - Read Only. Indicates VBus is above the A VBus valid threshold.
8 ID	USB ID - Read Only. 0 = A device, 1 = B device
7-6 -	This field is reserved. Reserved
5 IDPU	ID Pullup - Read/Write This bit provide control over the ID pull-up resistor; 0 = off, 1 = on [default]. When this bit is 0, the ID input will not be sampled.
4 DP	Data Pulsing - Read/Write. Setting this bit causes the pullup on DP to be asserted for data pulsing during SRP.
3 OT	OTG Termination - Read/Write. This bit must be set when the OTG device is in device mode, this controls the pulldown on DM.
2 -	This field is reserved. Reserved
1 VC	VBUS Charge - Read/Write. Setting this bit causes the VBus line to be charged. This is used for VBus pulsing during SRP.
0 VD	VBUS_Discharge - Read/Write. Setting this bit causes VBus to discharge through a resistor.

### 11.4.6.33 USB Device Mode (USBx\_USBMODE)

Address: Base address + 1A8h offset

**USBx\_USBMODE field descriptions**

Field	Description
31–16 -	This field is reserved. Reserved
15 -	This field is reserved. Reserved
14–5 -	This field is reserved. Reserved
4 SDIS	Stream Disable Mode. (0 - Inactive [default]; 1 - Active)  Device Mode: Setting to a '1' disables double priming on both RX and TX for low bandwidth systems. This mode ensures that when the RX and TX buffers are sufficient to contain an entire packet that the standard double buffering scheme is disabled to prevent overruns/underruns in bandwidth limited systems. Note: In High Speed Mode, all packets received are responded to with a NYET handshake when stream disable is active.  Host Mode: Setting to a '1' ensures that overruns/underruns of the latency FIFO are eliminated for low bandwidth systems where the RX and TX buffers are sufficient to contain the entire packet. Enabling stream disable also has the effect of ensuring the TX latency is filled to capacity before the packet is launched onto the USB.  <b>NOTE:</b> Time duration to pre-fill the FIFO becomes significant when stream disable is active. See <a href="#">TX FIFO Fill Tuning (USB_TXFILLTUNING)</a> and TTTFFILLTUNING [MPH Only] to characterize the adjustments needed for the scheduler when using this feature.

Table continues on the next page...

## USBx\_USBMODE field descriptions (continued)

Field	Description
	<b>NOTE:</b> The use of this feature substantially limits of the overall USB performance that can be achieved.
3 SLOM	Setup Lockout Mode. In device mode, this bit controls behavior of the setup lock mechanism. See <a href="#">Control Endpoint Operation Model</a> .  0 Setup Lockouts On (default); 1 Setup Lockouts Off (DCD requires use of Setup Data Buffer Tripwire in <a href="#">USB Command Register (USB_USBCMD)</a> .
2 ES	Endian Select - Read/Write. This bit can change the byte alignment of the transfer buffers to match the host microprocessor. The bit fields in the microprocessor interface and the data structures are unaffected by the value of this bit because they are based upon the 32-bit word.  Bit Meaning  0 Little Endian [Default] 1 Big Endian
CM	Controller Mode - R/WO. Controller mode is defaulted to the proper mode for host only and device only implementations. For those designs that contain both host & device capability, the controller defaults to an idle state and needs to be initialized to the desired operating mode after reset. For combination host/device controllers, this register can only be written once after reset. If it is necessary to switch modes, software must reset the controller by writing to the <i>RESET</i> bit in the USBCMD register before reprogramming this register.  For OTG controller core, reset value is '00b'.  For Host-only controller core, reset value is '11b'.  00 Idle [Default for combination host/device] 01 Reserved 10 Device Controller [Default for device only controller] 11 Host Controller [Default for host only controller]

## 11.4.6.34 Endpoint Setup Status (USBx\_ENDPTSETUPSTAT)

Address: Base address + 1ACh offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## USBx\_ENDPTSETUPSTAT field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
ENDPTSETUPSTAT	Setup Endpoint Status. For every setup transaction that is received, a corresponding bit in this register is set to one. Software must clear or acknowledge the setup transfer by writing a one to a respective bit after it has read the setup data from Queue head. The response to a setup packet as in the order of operations and total response time is crucial to limit bus time outs while the setup lock our mechanism is engaged. See <a href="#">Managing Endpoints</a> in the Device Operational Model.  This register is only used in device mode.

### 11.4.6.35 Endpoint Prime (USBx\_ENDPTPRIME)

This register is only used in device mode.

When software sets the prime bit for a given endpoint, the device controller loads the transfer descriptor, pointed to by the queue head, such that the endpoint is ready to transmit or receive when the host sends a request (IN/OUT token). The endpoint will NAK all requests from the host until the endpoint is primed. The controller will automatically re-prime the endpoint with a new transfer descriptor when one is found via the next\_dtd pointer of the current transfer descriptor. Hence, the prime bit must only be set by software when a descriptor is added to the queue head.

Address: Base address + 1B0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### USBx\_ENDPTPRIME field descriptions

Field	Description
31–24 -	This field is reserved. Reserved
23–16 PETB	Prime Endpoint Transmit Buffer - R/WS. For each endpoint a corresponding bit is used to request that a buffer is prepared for a transmit operation in order to respond to a USB IN/INTERRUPT transaction. Software should write a one to the corresponding bit when posting a new transfer descriptor to an endpoint queue head. Hardware automatically uses this bit to begin parsing for a new transfer descriptor from the queue head and prepare a transmit buffer. Hardware clears this bit when the associated endpoint(s) is (are) successfully primed.  <b>NOTE:</b> These bits are momentarily set by hardware during hardware re-priming operations when a dTD is retired, and the dQH is updated.  PETB[N] - Endpoint #N, N is in 0..7
15–8 -	This field is reserved. Reserved
PERB	Prime Endpoint Receive Buffer - R/WS. For each endpoint, a corresponding bit is used to request a buffer prepare for a receive operation for when a USB host initiates a USB OUT transaction. Software should write a one to the corresponding bit whenever posting a new transfer descriptor to an endpoint queue head. Hardware automatically uses this bit to begin parsing for a new transfer descriptor from the queue head and prepare a receive buffer. Hardware clears this bit when the associated endpoint(s) is (are) successfully primed.  <b>NOTE:</b> These bits are momentarily set by hardware during hardware re-priming operations when a dTD is retired, and the dQH is updated.  PERB[N] - Endpoint #N, N is in 0..7

### 11.4.6.36 Endpoint Flush (USBx\_ENDPTFLUSH)

This register is only used in device mode.

Address: Base address + 1B4h offset

#### USBx\_ENDPTSTAT field descriptions

Field	Description
31–24 -	This field is reserved. Reserved

Table continues on the next page...

**USBx\_ENDPTSTAT field descriptions (continued)**

Field	Description
23–16 ETBR	Endpoint Transmit Buffer Ready -- Read Only. One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There is always a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register.  <b>NOTE:</b> These bits are momentarily cleared by hardware during hardware endpoint re-priming operations when a dTD is retired, and the dQH is updated.  ETBR[N] - Endpoint #N, N is in 0..7
15–8 -	This field is reserved. Reserved
ERBR	Endpoint Receive Buffer Ready -- Read Only. One bit for each endpoint indicates status of the respective endpoint buffer. ## USBx\_ENDPTCTRL0 field descriptions

Field	Description
31–24 -	This field is reserved. Reserved
23 TXE	TX Endpoint Enable 1 Enabled Endpoint0 is always enabled.

Table continues on the next page...

**USBx\_ENDPTCTRL0 field descriptions (continued)**

Field	Description
22–20 -	This field is reserved. Reserved
19–18 TXT	TX Endpoint Type - Read/Write 00 - Control Endpoint0 is fixed as a Control End Point.
17 -	This field is reserved. Reserved
16 TXS	TX Endpoint Stall - Read/Write 0 End Point OK [Default] 1 End Point Stalled  Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It continues returning STALL until the bit is cleared by software or it is automatically cleared upon receipt of a new SETUP request.  After receiving a SETUP request, this bit will continue to be cleared by hardware until the associated ENDPTSETUPSTAT bit is cleared.  <b>NOTE:</b> There is a slight delay (50 clocks max.) between the endptsetupstat being cleared and hardware continuing to clear this bit. In most systems it is unlikely the DCD software will observe this delay. However, should the dcd observe that the stall bit is not set after writing a one to it then follow this procedure: continually write this stall bit until it is set or until a newsetup has been received by checking the associated endptsetupstat bit.
15–8 -	This field is reserved. Reserved
7 RXE	RX Endpoint Enable 1 Enabled Endpoint0 is always enabled.
6–4 -	This field is reserved. Reserved
3–2 RXT	RX Endpoint Type - Read/Write 00 Control Endpoint0 is fixed as a Control End Point.
1 -	This field is reserved. Reserved
0 RXS	RX Endpoint Stall - Read/Write 0 End Point OK. [Default] 1 End Point Stalled  Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It continues returning STALL until the bit is cleared by software or it is automatically cleared upon receipt of a new SETUP request.  After receiving a SETUP request, this bit will continue to be cleared by hardware until the associated ENDPTSETUPSTAT bit is cleared.

*Table continues on the next page...*

## USBx\_ENDPTCTRL0 field descriptions (continued)

Field	Description
	<b>NOTE:</b> There is a slight delay (50 clocks max.) between the endptsetupstat being cleared and hardware continuing to clear this bit. In most systems it is unlikely the dcd software will observe this delay. However, should the dcd observe that the stall bit is not set after writing a one to it then follow this procedure: continually write this stall bit until it is set or until a newsetup has been received by checking the associated endptsetupstat bit.

## 11.4.6.40 Endpoint Control 1 (USBx\_ENDPTCTRL1)

This is endpoint control register for endpoint 1 in device operation mode.

**NOTE**

If one endpoint direction is enabled and the paired endpoint of opposite direction is disabled then the unused direction type must be changed from the default control-type to any other type (that is Bulk-type). leaving an unconfigured endpoint control causes undefined behavior for the data pid tracking on the active endpoint/direction.

Address: Base address + 1C4h offset

This is endpoint control register for endpoint 5 in device operation mode.

**NOTE**

If one endpoint direction is enabled and the paired endpoint of opposite direction is disabled then the unused direction type must be changed from the default control-type to any other type (that is Bulk-type). leaving an unconfigured endpoint control causes undefined behavior for the data pid tracking on the active endpoint/direction.

## 11.5 Universal Serial Bus 2.0 Integrated PHY (USB-PHY)

### 11.5.1 USB PHY Overview

The chip contains 2 integrated USB 2.0 PHY macrocells capable of connecting to USB host/device systems at the USB low-speed (LS) rate of 1.5 Mbits/s, full-speed (FS) rate of 12 Mbits/s or at the USB 2.0 high-speed (HS) rate of 480 Mbits/s.

The integrated PHY provides a standard UTM interface. The USB<sub>n</sub>\_DN and USB<sub>n</sub>\_DP pins connect directly to a USB connector.

The following subsections describe the external interfaces, internal interfaces, major blocks, and programmable registers that comprise the integrated USB 2.0 PHY.

### 11.5.2 Operation

The UTM provides a 16-bit interface to the USB controller. This interface is clocked at 30 MHz.

- The digital portions of the USBPHY block include the UTMI, digital transmitter, digital receiver, and the programmable registers.
- The analog transceiver section comprises an analog receiver and an analog transmitter, as shown in [Figure 11-90](#).

### 11.5.2.1 UTMI

The UTMI block handles the line\_state bits, reset buffering, suspend distribution, transceiver speed selection, transceiver termination selection, and clock generation logic for the clocks derived from the PHY's 480 MHz USB PLL.

### 11.5.2.2 Digital Transmitter

The digital transmitter receives the 16-bit transmit data from the USB controller and handles the tx\_valid, tx\_validh and tx\_ready handshake.

In addition, it contains the transmit serializer that converts the 16-bit parallel words at 30 MHz to a single bitstream at 480 Mbit for high-speed or 12 Mbit for full-speed or 1.5 Mbit for low-speed. It does this while implementing the bit-stuffing algorithm and the NRZI encoder that are used to remove the DC component from the serial bitstream. The output of this encoder is sent to the low-speed (LS), full-speed (FS) or high-speed (HS) drivers in the analog transceiver section's transmitter block.

### 11.5.2.3 Digital Receiver

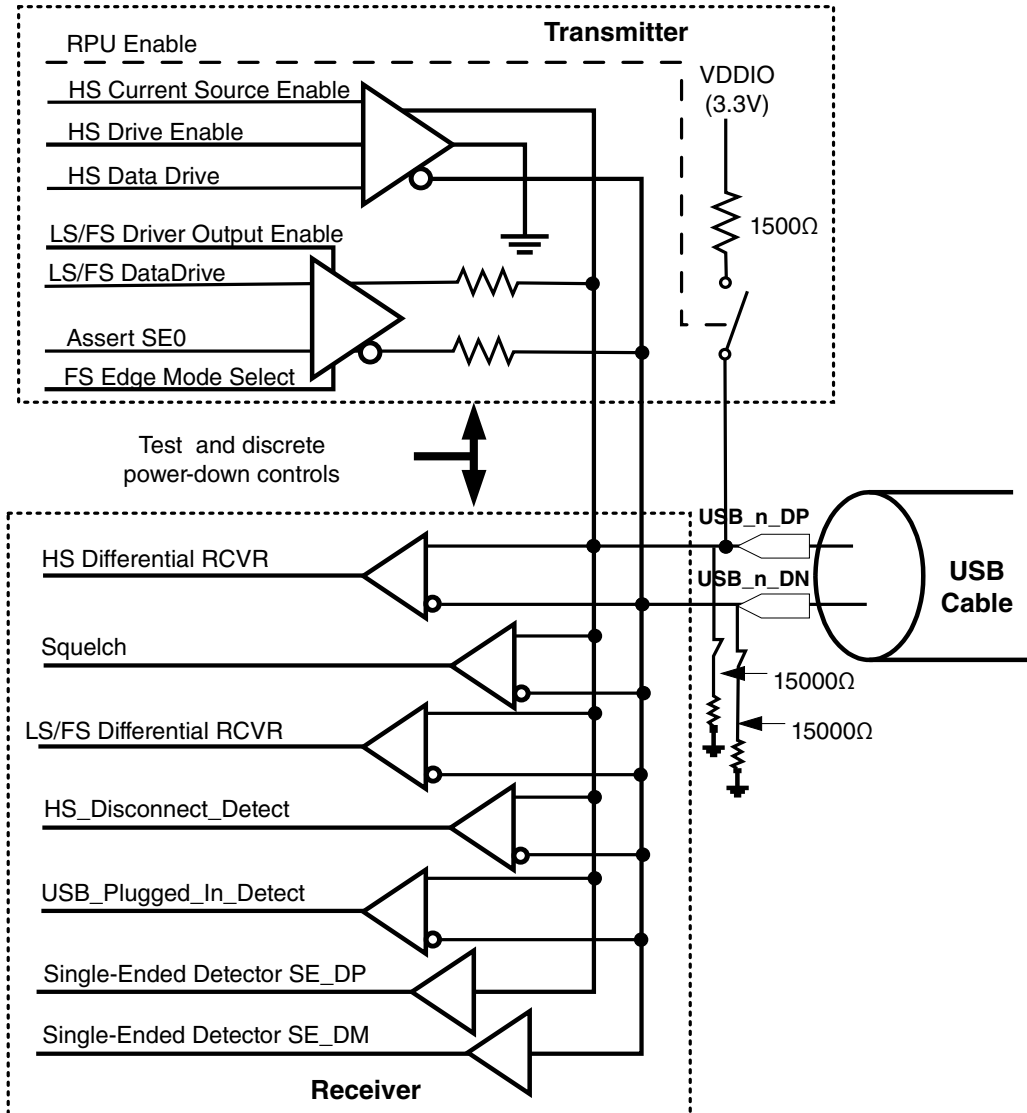

The digital receiver receives the raw serial bitstream from the low speed (LS) differential transceiver, full speed (FS) differential transceiver, and multiphase 480 MHz sampled data from the high speed (HS) differential transceiver.

As the phase of the USB host transmitter shifts relative to the local PLL, the receiver section's HS DLL tracks these changes to give a reliable sample of the incoming 480 Mbit/s bitstream. Since this sample point shifts relative to the PLL phase used by the digital logic, a rate-matching elastic buffer is provided to cross this clock domain boundary. Once the bitstream is in the local clock domain, an NRZI decoder and bit unstuffers restore the original payload data bitstream and pass it to a deserializer and holding register. The receive state machine handles the rx\_valid, rx\_validh, and handshake with the USB controller. The handshake is not interlocked, in that there is no rx\_ready signal coming from the controller. The controller must take each 16-bit value as presented by the PHY. The receive state machine provides an rx\_active signal to the controller that indicates when it is inside a valid packet (SYNC detected, and so on).

### 11.5.2.4 Analog Receiver

The analog receiver comprises five differential receivers, two single-ended receivers, and a 9X, 480 MHz HS data sampling module

, as shown in the figure below and described further in this section.

**Figure 11-90. USB 2.0 PHY Analog Transceiver Block Diagram**

#### 11.5.2.4.1 HS Differential Receiver

The high-speed differential receiver is both a differential analog receiver and threshold comparator. Its output is a one if the differential signal is greater than a 0-V threshold.

Otherwise, its output is 0. Its purpose is to discriminate the  $\pm 400$ -mV differential voltage resulting from the high-speed drivers current flow into the dual  $45\Omega$  terminations found on each pin of the differential pair. The envelope or squelch detector, described below, ensures that the differential signal has sufficient magnitude to be valid. The HS differential receiver tolerates up to 500 mV of common mode offset.

#### **11.5.2.4.2 Squelch Detector**

The squelch detector is a differential analog receiver and threshold comparator.

Its output is 1, if the differential magnitude is less than a nominal 100 mV threshold. Otherwise, its output is 0.

Its purpose is to invalidate the HS differential receiver when the incoming signal is simply too low to receive reliably.

#### **11.5.2.4.3 LS/FS Differential Receiver**

The low-speed/full-speed differential receiver is both a differential analog receiver and threshold comparator.

The crossover voltage falls between 1.3 V and 2.0 V. Its output is 1, when the USB<sub>n</sub>\_DP line is above the crossover point and the USB<sub>n</sub>\_DN line is below the crossover point. The digital receiver section decodes the receiver data into J or K state according to the speed.

#### **11.5.2.4.4 HS Disconnect Detector**

It is a differential analog receiver and threshold comparator. It outputs high when differential magnitude is greater than a nominal 575-mV threshold. Otherwise, it outputs low.

#### **11.5.2.4.5 Single-Ended USB\_DP Receiver**

The single-ended USB<sub>n</sub>\_DP receiver output is high whenever the USB<sub>n</sub>\_DP input is above its nominal 1.8 V threshold.

#### **11.5.2.4.6 Single-Ended USB\_DN Receiver**

The single-ended USB<sub>n</sub>\_DN receiver output is high whenever the USB<sub>n</sub>\_DN input is above its nominal 1.8 V threshold.

### 11.5.2.5 Analog Transmitter

The analog transmitter comprises two differential drivers: one for high-speed signaling and one for full-speed signaling. It also contains the switchable 1.5 K $\Omega$  pullup resistor.

See [Figure 11-90](#).

#### 11.5.2.5.1 Switchable High-Speed 45 $\Omega$ Termination Resistors

High-speed current mode differential signaling requires good 90  $\Omega$  differential termination at each end of the USB cable. This results from switching in 45  $\Omega$  terminating resistors from each signal line to ground at each end of the cable.

Because each signal is parallel terminated with 45  $\Omega$  at each end, each driver sees a 22.5  $\Omega$  load. This load impedance is much too low for full-speed signaling levels—hence the need for switchable high-speed terminating resistors. Switchable trimming resistors are provided to tune the actual termination resistance of each device, as shown in [Figure 11-91](#). The HW\_USBPHY\_TX\_TXCAL45DP bit field, for example, allows one of 16 trimming resistor values to be placed in parallel with the 45 $\Omega$  terminator on the USB\_*n*\_DP signal.

#### 11.5.2.5.2 Low-Speed/Full-Speed Differential Driver

The low-speed/full-speed differential drivers are essentially low-impedance pulldown devices that are switched in a differential mode for low-speed or full-speed signaling, that is, either one or the other device is turned on to signal the "J" state or the "K" state.

#### 11.5.2.5.3 High-Speed Differential Driver

The high-speed differential driver receives a 17.78 mA current from the constant current source ( $I_{ref}$ ) and essentially steers it down either the USB\_DP signal or the USB\_DN signal or alternatively to ground.

This current will produce approximately a 400 mV drop across the 22.5  $\Omega$  termination seen by the driver when it is steered onto one of the signal lines. The approximately 17.78 mA current source is referenced back to the integrated voltage-band-gap ( $V_{bg}$ ) circuit. The  $I_{ref}$ ,  $I_{bias}$ , and  $V$  to  $I$  circuits are shared with the integrated battery charger.

#### 11.5.2.5.4 Switchable 1.5K $\Omega$ USB\_DP Pullup Resistor

This product contains a switchable 1.5 K $\Omega$  pullup resistor on the USB\_*n*\_DP signal.

This resistor is switched on to indicate to the host/hub controller that a full-speed-capable device is on the USB cable, powered on, and ready. This resistor is switched off at power-on reset so the host does not recognize a USB device until the processor software enables the announcement of a full-speed device.

### 11.5.2.5.5 Switchable 15K $\Omega$ USB\_DP Pulldown Resistor

This product contains a switchable 15 K $\Omega$  pulldown resistor on both USB<sub>n</sub>\_DP and USB<sub>n</sub>\_DN signals. This is used in host mode to indicate to the device controller that a host is present.

Figure 11-91. USB 2.0 PHY Transmitter Block Diagram

## 11.5.2.6 Recommended Register Configuration for USB Certification

The register settings in this section are recommended for passing USB certification.

The following settings lower the J/K levels to certifiable limits:

`HW_USBPHY_TX_TXCAL45DP = 0x0`

`HW_USBPHY_TX_TXCAL45DN = 0x0`

`HW_USBPHY_TX_D_CAL = 0x7`

# Chapter 12

## Timers

### 12.1 General Purpose Timer (GPT)

#### 12.1.1 Overview

This chapter describes the General Purpose Timer (GPT) module interface. It is also a reference for software driver programming.

The GPT has a 32-bit up-counter. The timer counter value can be captured in a register using an event on an external pin. The capture trigger can be programmed to be a rising or/and falling edge. The GPT can also generate an event on the DO\_CMPOUT $n$  pins and an interrupt when the timer reaches a programmed value. The GPT has a 12-bit prescaler, which provides a programmable clock frequency derived from multiple clock sources.

Figure 12-1. GPT Block Diagram

The following figure shows the GPT functional clocking scheme.

### 12.1.1.1 Features

- One 32-bit up-counter with clock source selection, including external clock.
- Two input capture channels with a programmable trigger edge.
- Three output compare channels with a programmable output mode. A "forced compare" feature is also available.
- Can be programmed to be *active* in low power and debug modes.
- Interrupt generation at capture, compare, and rollover events.
- Restart or free-run modes for counter operations.

### 12.1.1.2 Modes and Operation

The GPT supports the modes described in the indicated sections:

- [Operating Modes](#)
  - [Restart Mode](#)
  - [Free-Run Mode](#)

### 12.1.2 External Signals

The GPT follows the IP Bus protocol for interfacing with the processor core. The GPT does not have *any interface signals with any other module inside the chip*, except for the clock and reset inputs (from the clock and reset controller module) and for the interrupt signals *to* the processor interrupt handler. There are functional and clock inputs, and functional output signals going outside the chip boundary.

The following table describes all block signals that connect off-chip.

**Table 12-1. GPT External Signals**

Signal	Description	Pad	Mode	Direction
GPT1_CAPTURE1	Input pin for a capture event for Input Capture Channel 1.	LCD1_DATA03	ALT1	I
GPT1_CAPTURE2	Input pin for a capture event for Input Capture Channel 2.	LCD1_DATA04	ALT1	I
GPT1_CLK	Input pin for an external clock that the counter can be operated at.	LCD1_DATA02	ALT1	I
GPT1_COMPARE1	Output pin that indicates a "compare event" occurrence in Output Compare Channel 1.	LCD1_RESET	ALT1	O
GPT1_COMPARE2	Output pin that indicates a "compare event" occurrence in Output Compare Channel 2.	LCD1_DATA00	ALT1	O
GPT1_COMPARE3	Output pin that indicates a "compare event" occurrence in Output Compare Channel 3.	LCD1_DATA01	ALT1	O
GPT2_CAPTURE1	Input pin for a capture event for Input Capture Channel 1.	ENET1_CRS	ALT3	I
GPT2_CAPTURE2	Input pin for a capture event for Input Capture Channel 2.	ENET1_COL	ALT3	I
GPT2_CLK	Input pin for an external clock that the counter can be operated at.	ENET1_RX_CLK	ALT3	I
GPT2_COMPARE1	Output pin that indicates a "compare event" occurrence in Output Compare Channel 1.	ENET1_TX_CTL	ALT3	O

*Table continues on the next page...*

**Table 12-1. GPT External Signals (continued)**

Signal	Description	Pad	Mode	Direction
GPT2_COMPARE2	Output pin that indicates a "compare event" occurrence in Output Compare Channel 2.	ENET1_TXC	ALT3	O
GPT2_COMPARE3	Output pin that indicates a "compare event" occurrence in Output Compare Channel 3.	ENET1_TX_CLK	ALT3	O
GPT3_CAPTURE1	Input pin for a capture event for Input Capture Channel 1.	SD3_CMD	ALT4	I
GPT3_CAPTURE2	Input pin for a capture event for Input Capture Channel 2.	SD3_DATA0	ALT4	I
GPT3_CLK	Input pin for an external clock that the counter can be operated at.	SD3_CLK	ALT4	I
GPT3_COMPARE1	Output pin that indicates a "compare event" occurrence in Output Compare Channel 1.	SD3_DATA1	ALT4	O
GPT3_COMPARE2	Output pin that indicates a "compare event" occurrence in Output Compare Channel 2.	SD3_DATA2	ALT4	O
GPT3_COMPARE3	Output pin that indicates a "compare event" occurrence in Output Compare Channel 3.	SD3_DATA3	ALT4	O
GPT4_CAPTURE1	Input pin for a capture event for Input Capture Channel 1.	SD2_CMD	ALT3	I
GPT4_CAPTURE2	Input pin for a capture event for Input Capture Channel 2.	SD2_DATA0	ALT3	I
GPT4_CLK	Input pin for an external clock that the counter can be operated at.	SD2_CLK	ALT3	I
GPT4_COMPARE1	Output pin that indicates a "compare event" occurrence in Output Compare Channel 1.	SD2_DATA1	ALT3	O
GPT4_COMPARE2	Output pin that indicates a "compare event" occurrence in Output Compare Channel 2.	SD2_DATA2	ALT3	O
GPT4_COMPARE3	Output pin that indicates a "compare event" occurrence in Output Compare Channel 3.	SD2_DATA3	ALT3	O

There are six signals (three input, three output) in the GPT module that *can be* connected to the chip pads.

### 12.1.2.1 External Clock Input

The GPT counter can be operated using an external clock from outside the device, and this is the input pin used for that purpose.

The external clock input GPT\_CLK is treated as asynchronous to the peripheral clock. To ensure proper operations of GPT, the external clock input frequency should be less than 1/4 of frequency of the peripheral clock. Hysteresis characteristics on this pad will be required because this is a clock input.

### 12.1.2.2 Input Capture Trigger Signals

The GPT counter value can be stored in a register, triggered by an event from *outside the device*.

A positive or/and negative edge on these signals GPT\_CAPTURE1 , GPT\_CAPTURE2 can trigger this capture event. These signals are treated as asynchronous to the peripheral clock. Only those transitions which occur *at least a single clock cycle* (the clock selected to run the counter) *after the previous recorded transition* are guaranteed to trigger a capture event.

### 12.1.2.3 Output Compare Signals

The output compare signals: GPT\_COMPARE1, GPT\_COMPARE2, GPT\_COMPARE3, indicate that output compare events have gone through a specified transition.

## 12.1.3 Signals

### 12.1.3.1 External Clock Input

The GPT counter can be operated using an external clock from outside the device, and this is the input pin used for that purpose.

The external clock input GPT\_CLK is treated as asynchronous to the peripheral clock. To ensure proper operations of GPT, the external clock input frequency should be less than 1/4 of frequency of the peripheral clock. Hysteresis characteristics on this pad will be required because this is a clock input.

### 12.1.3.2 Input Capture Trigger Signals

The GPT counter value can be stored in a register, triggered by an event from *outside the device*.

A positive or/and negative edge on these signals GPT\_CAPTURE1 , GPT\_CAPTURE2 can trigger this capture event. These signals are treated as asynchronous to the peripheral clock. Only those transitions which occur *at least a single clock cycle* (the clock selected to run the counter) *after the previous recorded transition* are guaranteed to trigger a capture event.

### 12.1.3.3 Output Compare Signals

The output compare signals: GPT\_COMPARE1, GPT\_COMPARE2, GPT\_COMPARE3, indicate that output compare events have gone through a specified transition.

### 12.1.4 Clocks

The clock that is input to the prescaler can be selected from 4 clock sources:

The following table describes the clock sources for GPT. Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

**Table 12-2. GPT Clocks**

Clock name	Clock Root	Description
ipg_clk	GPT_CLK_ROOT	Peripheral clock
ipg_clk_32k	CKIL_SYNC_CLK_ROOT	Low-frequency reference clock (32 kHz)
ipg_clk_highfreq	GPT_CLK_ROOT	High-frequency reference clock
ipg_clk_s	GPT_CLK_ROOT	Peripheral access clock

- High-Frequency Clock (ipg\_clk\_highfreq)

Provided by the Clock Controller Module (CCM), the High Frequency Clock is intended to be ON in Normal Power mode when the Peripheral Clock is turned OFF, thereby enabling the GPT to be operated using the High Frequency Clock *in Normal Power mode*. The CCM is expected to provide this clock *after* synchronizing it to the System Bus Clock in Normal functional mode; the CCM is also expected to switch to the *unsynchronized* version of the High Frequency Clock in a Low Power mode.

- Low-Reference Clock (ipg\_clk\_32k)

This 32 kHz Low Reference Clock (provided by the CCM) is intended to be ON in Low Power mode when the Peripheral Clock is turned OFF, thereby enabling the GPT to be operated using the Low Reference Clock in Low Power mode. The CCM

is expected to provide the Low Reference Clock *after* synchronizing it to the System Bus Clock in Normal functional mode; the CCM is also expected to switch to the *unsynchronized* version of the Low Reference Clock in a Low Power mode.

- Peripheral Clock (ipg\_clk)

If the Peripheral Clock or the External Clock is selected (CLKSRC=001 or 011) as Clock Source, then the Peripheral Clock will be ON in normal GPT operations. In Low Power modes, if the GPT is programmed to be disabled (STOPEN or WAITEN or DOZEN=0), then the Peripheral Clock can be switched OFF.

- External Clock

The External Clock comes from *outside the device* and can be selected to run the GPT counter. The External Clock is treated as *asynchronous to the Peripheral Clock*, and is synchronized to the Peripheral Clock, *inside* the module. Therefore, the External Clock frequency is limited to  $< 1/4$  frequency of the Peripheral Clock, for proper GPT operations. Note that in Low Power modes, *if* the Peripheral Clock is not available, then the External Clock *cannot be used* to run the counter.

- Crystal Oscillator Clock

This 24 MHz Crystal Oscillator Clock (provided by the CCM) is intended to be used against frequency change of Peripheral Clock changes to provide a more accurate timer clock for operation system. The CCM is expected to provide the 24 MHz Crystal Oscillator Clock *without* synchronizing it to the System Bus Clock in Normal functional mode. Synchronization is done in GPT module. Before synchronization, the 24 MHz Crystal Oscillator Clock is divided by a 24 MHz clock prescaler, to make sure the clock frequency less than half of System Bus Clock .

The clock input source is configured using the clock source field (CLKSRC, in the GPT\_CR control register). The clock input to the prescaler can be disabled by programming the CLKSRC bits (of the GPT\_CR control register) to 000. **The CLKSRC field value should be changed only after disabling the GPT** (by setting the EN bit in the GPT\_CR to 0).

The PRESCALER field selects the divide ratio of the input clock that drives the main counter. The prescaler can divide the input clock by a value (from 1 to 4096) and can be changed *at any time*. A change in the value of the PRESCALER field *immediately affects* the output clock frequency.

**Figure 12-2. Prescaler Value Change Timing Diagram**

## 12.1.5 Functional Description

This section provides a complete functional description of the GPT.

### 12.1.5.1 Operating Modes

The GPT counter can be programmed to work in either of two modes: Restart mode or Free-Run mode.

#### 12.1.5.1.1 Restart Mode

In Restart mode (selectable through the GPT Control Register GPT\_CR), when the counter reaches the compared value, the counter resets and starts again from 0x00000000. The Restart feature is associated only with Compare Channel 1.

Any write access to the Compare register of Channel 1 will reset the GPT counter. This is done to avoid possibly missing a compare event when compare value is changed from a higher value to lower value while counting is proceeding.

For the other two compare channels, when the compare event occurs the counter is *not reset*.

#### 12.1.5.1.2 Free-Run Mode

In Free-Run mode, when compare events occur for all 3 channels, the counter is *not reset*; instead the counter continues to count until 0xffffffff, and then rolls over (to 0x00000000).

### 12.1.5.2 Operation

The General Purpose Timer (GPT) has a single counter (GPT\_CNT) that is a 32-bit free-running *up-counter*, which starts counting *after it is enabled by software* (EN=1).

The counter's clock source is the output of the prescaler labelled "Prescaler output" in [Figure 12-1](#).

- If the GPT timer is disabled (EN=0), then the Main Counter *and* Prescaler Counter freeze their current count values. The ENMOD bit determines the value of the GPT counter when the EN bit is set and the Counter is enabled again.
  - If the ENMOD bit is set (=1), then the Main Counter and Prescaler Counter values are reset to 0, when GPT is enabled (EN=1).
  - If ENMOD bit is programmed to 0, then the Main Counter and Prescaler Counter restart counting from their frozen values, when GPT is enabled again (EN=1).
- If GPT is programmed to be disabled in a low power mode (STOP/WAIT), then the Main Counter and Prescaler Counter freeze at their current count values *when* GPT enters low power mode. When GPT exits a low power mode, the Main Counter and Prescaler Counter start counting from their frozen values *regardless* of the ENMOD bit value. Note that the GPT\_CNT can be read *at any time* by the processor, and that *both* Input Capture Channels use the *same* counter (GPT\_CNT).
- A hardware reset resets all the GPT registers to their respective reset values. All registers except the Output Compare Registers (OCR1, OCR2, OCR3) obtain a value of 0x0. The Compare registers are reset to 0xffffffff.
- The software reset (SWR bit in the GPT\_CR control register) resets *all* of the register bits *except* the EN, ENMOD, STOPEN, WAITEN, and DBGEN bits. The state of these bits is not affected by a software reset. Note that a software reset can be given *while the GPT is disabled*.

#### 12.1.5.2.1 Input Capture

There are two Input Capture Channels, and each Input Capture Channel has a dedicated capture pin, capture register and input edge detection/selection logic. Each input capture function has an associated status flag, and can cause the processor to make an interrupt service request.

When a selected edge transition occurs on an Input Capture pin, the contents of the GPT\_CNT is captured on the corresponding capture register and the appropriate interrupt status flag is set. An interrupt request can be generated when the transition is detected *if* its corresponding enable bit is set (in the Interrupt Register). The capture can be programmed to occur on the input pin's rising edge, falling edge, on both rising and falling edges, or the capture can be disabled. The events are synchronized with the clock that was selected to run the counter. Only those transitions that occur at least one clock

cycle (clock selected to run the counter) *after* the previous recorded transition will be guaranteed to trigger a capture event. There can be up to one clock cycle of uncertainty in the latching of the input transition. The Input Capture registers can be read *at any time* without affecting their values.

**Figure 12-3. Input Capture Event Timing**

### 12.1.5.2.2 Output Compare

The three Output Compare Channels *use the same counter* (GPT\_CNT) as the Input Capture Channels. When the programmed content of an Output Compare register matches the value in GPT\_CNT, an output compare status flag is set and an interrupt is generated (if the corresponding bit is set in the interrupt register). Consequently, the Output Compare timer pin will be set, cleared, toggled, not affected at all or provide an active-low pulse for one input clock period (subject to the restriction on the maximum frequency allowed on the pad) according to the mode bits (that were programmed).

There is also a "forced-compare" feature that allows the software to generate a compare event when required, *without the condition of the counter value that is equal to the compare value*. The action taken as a result of a forced compare is the same as when an output compare match occurs, *except that the status flags are not set and no interrupt can be generated*. Forced channels take programmed action immediately after the write to the force-compare bits. These bits are self-negating and always read as zeros.

Figure 12-4. Output Compare and Interrupt Timing

### 12.1.5.2.3 Interrupts

There are 6 different interrupts that are generated by the GPT. If the selected clock for running the counter is available, then *all interrupts can be generated in Low Power and Debug modes*.

- Rollover Interrupt

The Rollover Interrupt is generated when the GPT counter reaches 0xffffffff, then resets to 0x00000000 and continues counting. The Rollover Interrupt is enabled by the ROVIE bit in the GPT\_IR register; the associated status bit is the ROV bit in the GPT\_SR register.

- Input Capture Interrupt 1, 2

After a capture event occurs, the associated Input Capture Channel generates an interrupt. The "capture event" interrupts are enabled by the IF2IE and IF1IE bits (in the GPT\_IR register); the associated status bits are IF2 and IF1 (in the GPT\_SR register). The capture of the counter value because of a capture event is *not affected by a pending capture interrupt*. The Capture register is updated with a new counter value when a capture event occurs, regardless of whether that Capture Channels' interrupt has been serviced or not.

- Output Compare Interrupt 1, 2, 3

After a compare event occurs, the associated Output Compare Channel generates an interrupt. The "compare event" interrupts are enabled by the OF3IE, OF2IE, and OF1IE bits (in the GPT\_IR register); the associated status bits are OF3, OF2, and OF1 (in the GPT\_SR register). A "forced compare" does not generate an interrupt.

A *cumulative* interrupt line is also present, which is asserted whenever any of the above interrupts are posted. The cumulative interrupt line has *no* associated enables or status bits.

#### **12.1.5.2.4 Low Power Mode Behavior**

In Low Power modes, if the clock from the selected clock source is available (except for the External Clock, which can be used *only if* the Peripheral Clock is available), the counter will continue to run depending on whether the control bit for that mode is set. If the clock is not present or if the corresponding low power bit in the GPT\_CR control register is 0, the Main Counter and the Prescaler Counter freeze at their current values and resume counting (from their frozen values) when the Low Power mode is exited.

#### **12.1.5.2.5 Debug Mode Behavior**

In Debug mode, the modules in the device have the option of continuing to run or be halted.

- If the DBGEN bit is set, then the GPT timer will continue to run in Debug mode.
- If the DBGEN bit is not set (in the GPT\_CR control register), then the GPT timer is halted.

### **12.1.6 Initialization/ Application Information**

#### **12.1.6.1 Selecting the Clock Source**

The CLKSRC field in the GPT\_CR register selects the clock source. The CLKSRC field value should be changed only after disabling the GPT (EN=0).

The software sequence to be followed while changing clock source is:

1. Disable GPT by setting EN=0 in GPT\_CR register.
2. Disable GPT interrupt register (GPT\_IR).
3. Configure Output Mode to unconnected/ disconnected—Write zeros in OM3, OM2, and OM1 in GPT\_CR
4. Disable Input Capture Modes—Write zeros in IM1 and IM2 in GPT\_CR

5. Change clock source CLKSRC to the desired value in GPT\_CR register.
6. Assert the SWR bit in GPT\_CR register.
7. Clear GPT status register (GPT\_SR) (i.e., w1c).
8. Set ENMOD=1 in GPT\_CR register, to bring GPT counter to 0x00000000.
9. Enable GPT (EN=1) in GPT\_CR register.
10. Enable GPT interrupt register (GPT\_IR).

## 12.1.7 GPT Memory Map/Register Definition

The GPT has 10 user-accessible 32-bit registers, which are used to configure, operate, and monitor the state of the GPT.

An IP bus write access to the GPT Control Register (GPT\_CR) and the GPT Output Compare Register1 (GPT\_OCR1) results in *one cycle of wait state*, while other valid IP bus accesses incur 0 wait states.

Irrespective of the Response Select signal value, a Write access to the GPT Status Registers (Read-only registers GPT\_ICR1, GPT\_ICR2, GPT\_CNT) will generate a bus exception.

- If the Response Select signal is driven Low, then the Read/Write access to the *unimplemented* address space of GPT (*ips\_addr* is greater than or equal to \$BASE + \$028) will generate a bus exception.
- If the Response Select is driven High, then the Read/Write access to the unimplemented address space of GPT will *not* generate any error response (like a bus exception).

1 ENMOD	<p>GPT Enable mode.</p> <p>When the GPT is disabled (EN=0), then both the Main Counter and Prescaler Counter <i>freeze their current count values</i>. The ENMOD bit determines the value of the GPT counter when Counter is enabled again (if the EN bit is set).</p> <ul style="list-style-type: none"> <li>• If the ENMOD bit is 1, then the Main Counter and Prescaler Counter values are reset to 0 after GPT is enabled (EN=1).</li> <li>• If the ENMOD bit is 0, then the Main Counter and Prescaler Counter restart counting <i>from their frozen values</i> after GPT is enabled (EN=1).</li> <li>• If GPT is programmed to be disabled in a low power mode (STOP/WAIT), then the Main Counter and Prescaler Counter <i>freeze at their current count values</i> when the GPT enters low power mode.</li> <li>• When GPT exits low power mode, the Main Counter and Prescaler Counter start counting from their frozen values, regardless of the ENMOD bit value.</li> <li>• Setting the SWR bit will clear the Main Counter and Prescaler Counter values, regardless of the value of EN or ENMOD bits.</li> <li>• A hardware reset resets the ENMOD bit.</li> <li>• A software reset <i>does not affect</i> the ENMOD bit.</li> </ul> <p>0 GPT counter will retain its value when it is disabled. 1 GPT counter value is reset to 0 when it is disabled.</p>
0 EN	<p>GPT Enable.</p> <p>The EN bit is the GPT module enable bit.</p> <p><b>Before setting the EN bit</b>, we recommend that <i>all registers be properly programmed</i>.</p> <ul style="list-style-type: none"> <li>• A hardware reset resets the EN bit.</li> <li>• A software reset <i>does not affect</i> the EN bit.</li> </ul> <p>0 GPT is disabled. 1 GPT is enabled.</p>

### 12.1.7.2 GPT Prescaler Register (GPTx\_PR)

The GPT Prescaler Register (GPT\_PR) contains bits that determine the *divide value* of the clock that runs the counter.

Address: Base address + 4h offset

Bit	31	30	29	28	27	26	25	24		23	22	21	20	19	18	17	16
R	0																
W																	
Reset	0	0	0	0	0	0	0	0		0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8		7	6	5	4	3	2	1	0
R	PRESCALER24M				PRESCALER												
W																	
Reset	0	0	0	0	0	0	0	0		0	0	0	0	0	0	0	0

#### GPTx\_PR field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–12 PRESCALER24M	<p>Prescaler bits.</p> <p>24M crystal clock is divided by [PRESCALER24M + 1] before selected by the CLKSRC field. If 24M crystal clock is not selected, this feild takes no effect.</p> <p>0x0 Divide by 1                      0x1 Divide by 2                      ... ..                      0xF Divide by 16</p>
PRESCALER	<p>Prescaler bits.</p> <p>The clock selected by the CLKSRC field is divided by [PRESCALER + 1], and then used to run the counter.</p> <ul style="list-style-type: none"> <li>• A change in the value of the PRESCALER bits cause the Prescaler counter to reset and a new count period to start immediately.</li> <li>• See <a href="#">Figure 12-2</a> for the timing diagram.</li> </ul> <p>0x000 Divide by 1                      0x001 Divide by 2                      ... ..                      0xFFFF Divide by 4096</p>

### 12.1.7.3 GPT Status Register (GPTx\_SR)

The GPT Status Register (GPT\_SR) contains bits that indicate that a counter has rolled over, and if any event has occurred on the Input Capture and Output Compare channels. The bits are cleared by writing a 1 to them.

Address: Base address + 8h offset

Bit	31	30	29	28	27	26	25	24		23	22	21	20	19	18	17	16
R	0																
W	[Shaded]																
Reset	0	0	0	0	0	0	0	0		0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8		7	6	5	4	3	2	1	0
R	0								ROV	IF2	IF1	OF3	OF2	OF1			
W	[Shaded]								w1c	w1c	w1c	w1c	w1c	w1c			
Reset	0	0	0	0	0	0	0	0		0	0	0	0	0	0	0	0

#### GPTx\_SR field descriptions

Field	Description
31–6 Reserved	This read-only field is reserved and always has the value 0.
5 ROV	Rollover Flag. The ROV bit indicates that the counter has reached its <i>maximum possible value</i> and <i>rolled over</i> to 0 (from which the counter continues counting). The ROV bit is only set if the counter has reached 0xFFFFFFFF in both Restart and Free-Run modes.  0 Rollover has not occurred. 1 Rollover has occurred.
4 IF2	IF2 Input capture 2 Flag IF1 Input capture 1 Flag The IF $n$ bit indicates that a capture event has occurred on Input Capture channel $n$ .  0 Capture event has not occurred. 1 Capture event has occurred.
3 IF1	See IF2
2 OF3	OF3 Output Compare 3 Flag OF2 Output Compare 2 Flag OF1 Output Compare 1 Flag The OF $n$ bit indicates that a compare event has occurred on Output Compare channel $n$ .  0 Compare event has not occurred. 1 Compare event has occurred.

Table continues on the next page...

### GPTx\_SR field descriptions (continued)

Field	Description
1 OF2	See OF3
0 OF1	See OF3

### 12.1.7.4 GPT Interrupt Register (GPTx\_IR)

The GPT Interrupt Register (GPT\_IR) contains bits that control whether interrupts are generated after rollover, input capture and output compare events.

Address: Base address + Ch offset

### GPTx\_IR field descriptions

Field	Description
31–6 Reserved	This read-only field is reserved and always has the value 0.
5 ROVIE	Rollover Interrupt Enable. The ROVIE bit controls the Rollover interrupt.  0 Rollover interrupt is disabled. 1 Rollover interrupt enabled.
4 IF2IE	IF2IE Input capture 2 Interrupt Enable IF1IE Input capture 1 Interrupt Enable The IFnIE bit controls the IFnIE Input Capture n Interrupt Enable.  0 IF2IE Input Capture n Interrupt Enable is disabled. 1 IF2IE Input Capture n Interrupt Enable is enabled.

Table continues on the next page...

## GPTx\_IR field descriptions (continued)

Field	Description
3 IF1IE	See IF2IE
2 OF3IE	OF3IE Output Compare 3 Interrupt Enable OF2IE Output Compare 2 Interrupt Enable OF1IE Output Compare 1 Interrupt Enable The OF $n$ IE bit controls the Output Compare Channel $n$ interrupt. 0 Output Compare Channel $n$ interrupt is disabled. 1 Output Compare Channel $n$ interrupt is enabled.
1 OF2IE	See OF3IE
0 OF1IE	See OF3IE

## 12.1.7.5 GPT Output Compare Register 1 (GPTx\_OCR1)

The GPT Compare Register 1 (GPT\_OCR1) holds the value that determines when a compare event will be generated on Output Compare Channel 1. Any write access to the Compare register of Channel 1 while in Restart mode (FRR=0) will reset the GPT counter.

An IP Bus Write access to the GPT Output Compare Register1 (GPT\_OCR1) occurs *after* one cycle of wait state; an IP Bus Read access occurs *immediately* (0 wait states).

Address: Base address + 10h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	COMP																															
W																																
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

## GPTx\_OCR1 field descriptions

Field	Description
COMP	Compare Value. When the counter value equals the COMP bit field value, a compare event is generated on Output Compare Channel 1.

### 12.1.7.6 GPT Output Compare Register 2 (GPTx\_OCR2)

The GPT Compare Register 2 (GPT\_OCR2) holds the value that determines when a compare event will be generated on Output Compare Channel 2.

Address: Base address + 14h offset

#### GPTx\_OCR2 field descriptions

Field	Description
COMP	Compare Value. When the counter value equals the COMP bit field value, a compare event is generated on Output Compare Channel 2.

### 12.1.7.7 GPT Output Compare Register 3 (GPTx\_OCR3)

The GPT Compare Register 3 (GPT\_OCR3) holds the value that determines when a compare event will be generated on Output Compare Channel 3.

Address: Base address + 18h offset

#### GPTx\_OCR3 field descriptions

Field	Description
COMP	Compare Value. When the counter value equals the COMP bit field value, a compare event is generated on Output Compare Channel 3.

### 12.1.7.8 GPT Input Capture Register 1 (GPTx\_ICR1)

The GPT Input Capture Register 1 (GPT\_ICR1) is a read-only register that holds the value *that was in the counter during the last capture event* on Input Capture Channel 1.

Address: Base address + 1Ch offset

#### GPTx\_ICR1 field descriptions

Field	Description
CAPT	Capture Value. After a capture event on Input Capture Channel 1 occurs, the current value of the counter is loaded into GPT Input Capture Register 1.

### 12.1.7.9 GPT Input Capture Register 2 (GPTx\_ICR2)

The GPT Input capture Register 2 (GPT\_ICR2) is a read-only register which holds the value that was in the counter during the last capture event on input capture channel 2.

Address: Base address + 20h offset

#### GPTx\_ICR2 field descriptions

Field	Description
CAPT	Capture Value. After a capture event on Input Capture Channel 2 occurs, the current value of the counter is loaded into GPT Input Capture Register 2.

### 12.1.7.10 GPT Counter Register (GPTx\_CNT)

The GPT Counter Register (GPT\_CNT) is the main counter's register. GPT\_CNT is a read-only register and can be read *without affecting the counting process* of the GPT.

Address: Base address + 24h offset

#### GPTx\_CNT field descriptions

Field	Description
COUNT	Counter Value. The COUNT bits show the current count value of the GPT counter.

## 12.2 Flextimer (FTM)

### 12.2.1 Introduction

The FlexTimer module (FTM) is a two-to-eight channel timer that supports input capture, output compare, and the generation of PWM signals to control electric motor and power management applications. The FTM time reference is a 16-bit counter that can be used as an unsigned or signed counter.

#### NOTE

The number of channels supported can vary for each instance of the FTM module on a chip. See the chip-specific FTM information to see how many channels are supported for each module instance. For example, if a module instance supports only six channels, references to channel numbers 6 and 7 do not apply for that instance.

### 12.2.1.1 FlexTimer philosophy

The FlexTimer is built upon a simple timer, the HCS08 Timer PWM Module – TPM, used for many years on Freescale's 8-bit microcontrollers. The FlexTimer extends the functionality to meet the demands of motor control, digital lighting solutions, and power conversion, while providing low cost and backwards compatibility with the TPM module.

Several key enhancements are made:

- Signed up counter
- Deadtime insertion hardware
- Enhanced triggering functionality
- Initialization and polarity control

All of the features common with the TPM have fully backwards compatible register assignments. The FlexTimer can also use code on the same core platform without change to perform the same functions.

Motor control and power conversion features have been added through a dedicated set of registers and defaults turn off all new features. The new features, such as hardware deadtime insertion, polarity, and output forcing and masking, greatly reduce loading on the execution software and are usually each controlled by a group of registers.

FlexTimer input triggers can be from comparators, ADC, or other submodules to initiate timer functions automatically. These triggers can be linked in a variety of ways during integration of the sub modules so please note the options available for used FlexTimer configuration.

More than one FlexTimers may be synchronized to provide a larger timer with their counters incrementing in unison, assuming the initialization, the input clocks, the initial and final counting values are the same in each FlexTimer.

All main user access registers are buffered to ease the load on the executing software. A number of trigger options exist to determine which registers are updated with this user defined data.

### 12.2.1.2 Features

The FTM features include:

- FTM source clock is the system clock.
- Prescaler divide-by 1, 2, 4, 8, 16, 32, 64, or 128
- 16-bit counter

- It can be a free-running counter or a counter with initial and final value
- The counting can be up or up-down
- Each channel can be configured for input capture, output compare, or edge-aligned PWM mode
- In Input Capture mode:
  - The capture can occur on rising edges, falling edges or both edges
  - An input filter can be selected for some channels
- In Output Compare mode the output signal can be set, cleared, or toggled on match
- All channels can be configured for center-aligned PWM mode
- Each pair of channels can be combined to generate a PWM signal with independent control of both edges of PWM signal
- The FTM channels can operate as pairs with equal outputs, pairs with complementary outputs, or independent channels with independent outputs
- The deadtime insertion is available for each complementary pair
- Generation of match triggers
- Initialization trigger
- Software control of PWM outputs
- The polarity of each channel is configurable
- The generation of an interrupt per channel
- The generation of an interrupt when the counter overflows
- Synchronized loading of write buffered FTM registers
- Write protection for critical registers
- Backwards compatible with TPM
- Testing of input captures for a stuck at zero and one conditions
- Dual edge capture for pulse and period width measurement
- Quadrature decoder with input filters, relative position counting, and interrupt on position count or capture of position count on external event

### 12.2.1.3 Modes of operation

When the chip is in an active BDM mode, the FTM temporarily suspends all counting until the chip returns to normal user operating mode. During Stop mode, all FTM input clocks are stopped, so the FTM is effectively disabled until clocks resume. During Wait mode, the FTM continues to operate normally. If the FTM does not need to produce a real time reference or provide the interrupt sources needed to wake the chip from Wait mode, the power can then be saved by disabling FTM functions before entering Wait mode.

### 12.2.1.4 Block diagram

The FTM uses one input/output (I/O) pin per channel, CH<sub>n</sub> (FTM channel (n)) where n is the channel number (0–7).

The following figure shows the FTM structure. The central component of the FTM is the 16-bit counter with programmable initial and final values and its counting can be up or up-down.

#### NOTE

The number of channels supported can vary for each instance of the FTM module on a chip. See the chip-specific FTM information to see how many channels are supported for each module instance. For example, if a module instance supports only six channels, references to channel numbers 6 and 7 do not apply for that instance.

# Flextimer (FTM)

**Figure 12-5. FTM block diagram**

## 12.2.2 FTM signal descriptions

Table 12-3 shows the user-accessible signals for the FTM.

**Table 12-3. FTM signal descriptions**

Signal	Description	I/O	Function
CHn	FTM channel (n), where n can be 7-0	I/O	Each FTM channel can be configured to operate either as input or output. The direction associated with each channel, input or output, is selected according to the mode assigned for that channel.
PHA	Quadrature decoder phase A input. Input pin associated with quadrature decoder phase A.	I	The quadrature decoder phase A input is used as the Quadrature Decoder mode is selected. The phase A input signal is one of the signals that control the FTM counter increment or decrement in the <a href="#">Quadrature Decoder mode</a> .
PHB	Quadrature decoder phase B input. Input pin associated with quadrature decoder phase B.	I	The quadrature decoder phase B input is used as the Quadrature Decoder mode is selected. The phase B input signal is one of the signals that control the FTM counter increment or decrement in the <a href="#">Quadrature Decoder mode</a> .

## 12.2.3 Memory map and register definition

### 12.2.3.1 Memory map

This section presents a high-level summary of the FTM registers and how they are mapped.

The registers and bits of an unavailable function in the FTM remain in the memory map and in the reset value, but they have no active function.

#### Note

Do not write in the region from the CNTIN register through the PWMLOAD register when  $FTMEN = 0$ .

#### NOTE

The number of channels supported can vary for each instance of the FTM module on a chip. See the chip-specific FTM information to see how many channels are supported for each module instance. For example, if a module instance supports only six channels, references to channel numbers 6 and 7 do not apply for that instance.

## 12.2.3.2 Register descriptions

Accesses to reserved addresses result in transfer errors. Registers for absent channels are considered reserved.

### 12.2.3.3 Status And Control (FTMx\_SC)

SC contains the overflow status flag and control bits used to configure the interrupt enable, FTM configuration, clock source, and prescaler factor. These controls relate to all channels within this module.

Address: Base address + 0h offset

**FTMx\_SC field descriptions**

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 TOF	<p>Timer Overflow Flag</p> <p>Set by hardware when the FTM counter passes the value in the MOD register. The TOF bit is cleared by reading the SC register while TOF is set and then writing a 0 to TOF bit. Writing a 1 to TOF has no effect.</p> <p>If another FTM overflow occurs between the read and write operations, the write operation has no effect; therefore, TOF remains set indicating an overflow has occurred. In this case, a TOF interrupt request is not lost due to the clearing sequence for a previous TOF.</p> <p>0 FTM counter has not overflowed. 1 FTM counter has overflowed.</p>

*Table continues on the next page...*

## FTMx\_SC field descriptions (continued)

Field	Description
25 TOIE	<p>Timer Overflow Interrupt Enable</p> <p>Enables FTM overflow interrupts.</p> <p>0 Disable TOF interrupts. Use software polling. 1 Enable TOF interrupts. An interrupt is generated when TOF equals one.</p>
26 CPWMS	<p>Center-Aligned PWM Select</p> <p>Selects CPWM mode. This mode configures the FTM to operate in Up-Down Counting mode. This field is write protected. It can be written only when MODE[WPDIS] = 1.</p> <p>0 FTM counter operates in Up Counting mode. 1 FTM counter operates in Up-Down Counting mode.</p>
27–28 CLKS	<p>Clock Source Selection</p> <p>Selects FTM counter clock sources. This field is write protected. It can be written only when MODE[WPDIS] = 1.</p> <p>00 No clock selected. This in effect disables the FTM counter. 01 System clock 10 Reserved</p>
29–31 PS	<p>Prescale Factor Selection</p> <p>Selects one of 8 division factors for the clock source selected by CLKS. The new prescaler factor affects the clock source on the next system clock cycle after the new value is updated into the register bits. This field is write protected. It can be written only when MODE[WPDIS] = 1.</p> <p>000 Divide by 1 001 Divide by 2 010 Divide by 4 011 Divide by 8 100 Divide by 16 101 Divide by 32 110 Divide by 64 111 Divide by 128</p>

### 12.2.3.4 Counter (FTMx\_CNT)

The CNT register contains the FTM counter value.

Reset clears the CNT register. Writing any value to COUNT updates the counter with its initial value, CNTIN.

When BDM is active, the FTM counter is frozen. This is the value that you may read.

## Flextimer (FTM)

Address: Base address + 4h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

### FTMx\_CNT field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Counter Value

## 12.2.3.5 Modulo (FTMx\_MOD)

The Modulo register contains the modulo value for the FTM counter. After the FTM counter reaches the modulo value, the overflow flag (TOF) becomes set at the next clock, and the next value of FTM counter depends on the selected counting method; see [Counter](#).

Writing to the MOD register latches the value into a buffer. The MOD register is updated with the value of its write buffer according to [Registers updated from write buffers](#).

If FTMEN = 0, this write coherency mechanism may be manually reset by writing to the SC register whether BDM is active or not.

Initialize the FTM counter, by writing to CNT, before writing to the MOD register to avoid confusion about when the first counter overflow will occur.

Address: Base address + 8h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

**Table 12-4. Mode, edge, and level selection (continued)**

DECAPEN	COMBINE	CPWMS	MSnB:MSnA	ELSnB:ELSnA	Mode	Configuration
1	0	0	X0	See the following table (Table 12-5).	Dual Edge Capture	One-Shot Capture mode
			X1			Continuous Capture mode

**Table 12-5. Dual Edge Capture mode — edge polarity selection**

ELSnB	ELSnA	Channel Port Enable	Detected Edges
0	0	Disabled	No edge
0	1	Enabled	Rising edge
1	0	Enabled	Falling edge
1	1	Enabled	Rising and falling edges

Address: Base address + Ch offset + (8d × i), where i=0d to 7d

## FTMx\_CnSC field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 CHF	Channel Flag  Set by hardware when an event occurs on the channel. CHF is cleared by reading the CSC register while CHnF is set and then writing a 0 to the CHF bit. Writing a 1 to CHF has no effect.  If another event occurs between the read and write operations, the write operation has no effect; therefore, CHF remains set indicating an event has occurred. In this case a CHF interrupt request is not lost due to the clearing sequence for a previous CHF.  0 No channel event has occurred. 1 A channel event has occurred.
25 CHIE	Channel Interrupt Enable  Enables channel interrupts.  0 Disable channel interrupts. Use software polling. 1 Enable channel interrupts.
26 MSB	Channel Mode Select  Used for further selections in the channel logic. Its functionality is dependent on the channel mode. See <a href="#">Table 12-4</a> .  This field is write protected. It can be written only when MODE[WPDIS] = 1.
27 MSA	Channel Mode Select  Used for further selections in the channel logic. Its functionality is dependent on the channel mode. See <a href="#">Table 12-4</a> .  This field is write protected. It can be written only when MODE[WPDIS] = 1.
28 ELSB	Edge or Level Select  The functionality of ELSB and ELSA depends on the channel mode. See <a href="#">Table 12-4</a> .  This field is write protected. It can be written only when MODE[WPDIS] = 1.
29 ELSA	Edge or Level Select  The functionality of ELSB and ELSA depends on the channel mode. See <a href="#">Table 12-4</a> .  This field is write protected. It can be written only when MODE[WPDIS] = 1.
30 ICRST	FTM counter reset by the selected input capture event.  FTM counter reset is driven by the selected event of the channel (n) in the Input Capture mode.  This field is write protected. It can be written only when MODE[WPDIS] = 1.  0 FTM counter is not reset when the selected channel (n) input event is detected. 1 FTM counter is reset when the selected channel (n) input event is detected.
31 DMA	DMA Enable  Enables DMA transfers for the channel.  0 Disable DMA transfers. 1 Enable DMA transfers.

### 12.2.3.7 Channel (n) Value (FTMx\_CnV)

These registers contain the captured FTM counter value for the input modes or the match value for the output modes.

In Input Capture, Capture Test, and Dual Edge Capture modes, any write to a CnV register is ignored.

In output modes, writing to a CnV register latches the value into a buffer. A CnV register is updated with the value of its write buffer according to [Registers updated from write buffers](#).

If FTMMEN = 0, this write coherency mechanism may be manually reset by writing to the CnSC register whether BDM mode is active or not.

Address: Base address + 10h offset + (8d × i), where i=0d to 7d

#### FTMx\_CnV field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 VAL	Channel Value Captured FTM counter value of the input modes or the match value for the output modes

### 12.2.3.8 Counter Initial Value (FTMx\_CNTIN)

The Counter Initial Value register contains the initial value for the FTM counter.

Writing to the CNTIN register latches the value into a buffer. The CNTIN register is updated with the value of its write buffer according to [Registers updated from write buffers](#).

When the FTM clock is initially selected, by writing a non-zero value to the CLKS bits, the FTM counter starts with the value 0x0000. To avoid this behavior, before the first write to select the FTM clock, write the new value to the the CNTIN register and then initialize the FTM counter by writing any value to the CNT register.

Address: Base address + 4Ch offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

### FTMx\_CNTIN field descriptions

Field	Description
0–15 Reserved	This field is reserved.
16–31 INIT	Initial Value Of The FTM Counter

### 12.2.3.9 Capture And Compare Status (FTMx\_STATUS)

The STATUS register contains a copy of the status flag CHnF bit in CnSC for each FTM channel for software convenience.

Each CHnF bit in STATUS is a mirror of CHnF bit in CnSC. All CHnF bits can be checked using only one read of STATUS. All CHnF bits can be cleared by reading STATUS followed by writing 0x00 to STATUS.

Hardware sets the individual channel flags when an event occurs on the channel. CHnF is cleared by reading STATUS while CHnF is set and then writing a 0 to the CHnF bit. Writing a 1 to CHnF has no effect.

If another event occurs between the read and write operations, the write operation has no effect; therefore, CHnF remains set indicating an event has occurred. In this case, a CHnF interrupt request is not lost due to the clearing sequence for a previous CHnF.

### FTMx\_STATUS field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 CH7F	Channel 7 Flag See the register description. 0 No channel event has occurred. 1 A channel event has occurred.
25 CH6F	Channel 6 Flag See the register description. 0 No channel event has occurred. 1 A channel event has occurred.
26 CH5F	Channel 5 Flag See the register description. 0 No channel event has occurred. 1 A channel event has occurred.
27 CH4F	Channel 4 Flag See the register description. 0 No channel event has occurred. 1 A channel event has occurred.
28 CH3F	Channel 3 Flag See the register description. 0 No channel event has occurred. 1 A channel event has occurred.
29 CH2F	Channel 2 Flag See the register description.

*Table continues on the next page...*

## FTMx\_STATUS field descriptions (continued)

Field	Description
	0 No channel event has occurred. 1 A channel event has occurred.
30 CH1F	Channel 1 Flag  See the register description.  0 No channel event has occurred. 1 A channel event has occurred.
31 CH0F	Channel 0 Flag  See the register description.  0 No channel event has occurred. 1 A channel event has occurred.

## 12.2.3.10 Features Mode Selection (FTMx\_MODE)

This register contains the global enable bit for FTM-specific features and the control bits used to configure:

- Capture Test mode
- PWM synchronization
- Write protection
- Channel output initialization

These controls relate to all channels within this module.

Address: Base address + 54h offset

Bit	0	1	2	3	4	5	6	7		8	9	10	11	12	13	14	15	
R	0																	
W	[Shaded]

W	[Shaded]								[Shaded]					CAPTEST	PWMSYNC	WPDIS	INIT	FTMEN
Reset	0	0	0	0	0	0	0	0		0	0	0	0	0	0	1	0	0

## FTMx\_MODE field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 CAPTEST	Capture Test Mode Enable Enables the capture test mode. This field is write protected. It can be written only when MODE[WPDIS] = 1.  0 Capture test mode is disabled. 1 Capture test mode is enabled.
28 PWMSYNC	PWM Synchronization Mode Selects which triggers can be used by MOD, CnV, OUTMASK, and FTM counter synchronization. See <a href="#">PWM synchronization</a> . The PWMSYNC bit configures the synchronization when SYNCMODE is 0.  0 No restrictions. Software and hardware triggers can be used by MOD, CnV, OUTMASK, and FTM counter synchronization. 1 Software trigger can only be used by MOD and CnV synchronization, and hardware triggers can only be used by OUTMASK and FTM counter synchronization.
29 WPDIS	Write Protection Disable When write protection is enabled (WPDIS = 0), write protected bits cannot be written. When write protection is disabled (WPDIS = 1), write protected bits can be written. The WPDIS bit is the negation of the WPEN bit. WPDIS is cleared when 1 is written to WPEN. WPDIS is set when WPEN bit is read as a 1 and then 1 is written to WPDIS. Writing 0 to WPDIS has no effect.  0 Write protection is enabled. 1 Write protection is disabled.
30 INIT	Initialize The Channels Output When a 1 is written to INIT bit the channels output is initialized according to the state of their corresponding bit in the OUTINIT register. Writing a 0 to INIT bit has no effect. The INIT bit is always read as 0.
31 FTMEN	FTM Enable This field is write protected. It can be written only when MODE[WPDIS] = 1.  0 TPM compatibility. Free running counter and synchronization compatible with TPM. 1 Free running counter and synchronization are different from TPM behavior.

### 12.2.3.11 Synchronization (FTMx\_SYNC)

This register configures the PWM synchronization.

A synchronization event can perform the synchronized update of MOD, CV, and OUTMASK registers with the value of their write buffer and the FTM counter initialization.

**NOTE**

The software trigger, SWSYNC bit, and hardware triggers TRIG0, TRIG1, and TRIG2 bits have a potential conflict if used together when SYNCMODE = 0. Use only hardware or software triggers but not both at the same time, otherwise unpredictable behavior is likely to happen.

The selection of the loading point, CNTMAX and CNTMIN bits, is intended to provide the update of MOD, CNTIN, and CnV registers across all enabled channels simultaneously. The use of the loading point selection together with SYNCMODE = 0 and hardware trigger selection, TRIG0, TRIG1, or TRIG2 bits, is likely to result in unpredictable behavior.

The synchronization event selection also depends on the PWMSYNC (MODE register) and SYNCMODE (SYNCONF register) bits. See [PWM synchronization](#).

#### FTMx\_OUTINIT field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 CH7OI	Channel 7 Output Initialization Value  Selects the value that is forced into the channel output when the initialization occurs.  0 The initialization value is 0. 1 The initialization value is 1.
25 CH6OI	Channel 6 Output Initialization Value  Selects the value that is forced into the channel output when the initialization occurs.  0 The initialization value is 0. 1 The initialization value is 1.
26 CH5OI	Channel 5 Output Initialization Value  Selects the value that is forced into the channel output when the initialization occurs.  0 The initialization value is 0. 1 The initialization value is 1.
27 CH4OI	Channel 4 Output Initialization Value  Selects the value that is forced into the channel output when the initialization occurs.  0 The initialization value is 0. 1 The initialization value is 1.
28 CH3OI	Channel 3 Output Initialization Value  Selects the value that is forced into the channel output when the initialization occurs.

*Table continues on the next page...*

**FTMx\_OUTINIT field descriptions (continued)**

Field	Description
	0 The initialization value is 0. 1 The initialization value is 1.
29 CH2OI	Channel 2 Output Initialization Value  Selects the value that is forced into the channel output when the initialization occurs.  0 The initialization value is 0. 1 The initialization value is 1.
30 CH1OI	Channel 1 Output Initialization Value  Selects the value that is forced into the channel output when the initialization occurs.  0 The initialization value is 0. 1 The initialization value is 1.
31 CH0OI	Channel 0 Output Initialization Value  Selects the value that is forced into the channel output when the initialization occurs.  0 The initialization value is 0. 1 The initialization value is 1.

**12.2.3.13 Output Mask (FTMx\_OUTMASK)**

This register provides a mask for each FTM channel. The mask of a channel determines if its output responds, that is, it is masked or not, when a match occurs. This feature is used for BLDC control where the PWM signal is presented to an electric motor at specific times to provide electronic commutation.

Any write to the OUTMASK register, stores the value in its write buffer. The register is updated with the value of its write buffer according to [PWM synchronization](#).

## FTMx\_OUTMASK field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 CH7OM	Channel 7 Output Mask  Defines if the channel output is masked or unmasked.  0 Channel output is not masked. It continues to operate normally. 1 Channel output is masked. It is forced to its inactive state.
25 CH6OM	Channel 6 Output Mask  Defines if the channel output is masked or unmasked.  0 Channel output is not masked. It continues to operate normally. 1 Channel output is masked. It is forced to its inactive state.
26 CH5OM	Channel 5 Output Mask  Defines if the channel output is masked or unmasked.  0 Channel output is not masked. It continues to operate normally. 1 Channel output is masked. It is forced to its inactive state.
27 CH4OM	Channel 4 Output Mask  Defines if the channel output is masked or unmasked.  0 Channel output is not masked. It continues to operate normally. 1 Channel output is masked. It is forced to its inactive state.
28 CH3OM	Channel 3 Output Mask  Defines if the channel output is masked or unmasked.  0 Channel output is not masked. It continues to operate normally. 1 Channel output is masked. It is forced to its inactive state.
29 CH2OM	Channel 2 Output Mask  Defines if the channel output is masked or unmasked.  0 Channel output is not masked. It continues to operate normally. 1 Channel output is masked. It is forced to its inactive state.
30 CH1OM	Channel 1 Output Mask  Defines if the channel output is masked or unmasked.  0 Channel output is not masked. It continues to operate normally. 1 Channel output is masked. It is forced to its inactive state.
31 CH0OM	Channel 0 Output Mask  Defines if the channel output is masked or unmasked.  0 Channel output is not masked. It continues to operate normally. 1 Channel output is masked. It is forced to its inactive state.

### 12.2.3.14 Function For Linked Channels (FTMx\_COMBINE)

This register contains the control bits used to configure the synchronization, deadtime insertion, Dual Edge Capture mode, Complementary, and Combine mode for each pair of channels (n) and (n+1), where n equals 0, 2, 4, and 6.

Address: Base address + 64h offset

**FTMx\_DEADTIME field descriptions**

Field	Description
0–23 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>

*Table continues on the next page...*

## FTMx\_DEADTIME field descriptions (continued)

Field	Description
24–25 DTPS	<p>Deadtime Prescaler Value</p> <p>Selects the division factor of the system clock. This prescaled clock is used by the deadtime counter.</p> <p>This field is write protected. It can be written only when MODE[WPDIS] = 1.</p> <p>0x Divide the system clock by 1.            10 Divide the system clock by 4.            11 Divide the system clock by 16.</p>
26–31 DTVVAL	<p>Deadtime Value</p> <p>Selects the deadtime insertion value for the deadtime counter. The deadtime counter is clocked by a scaled version of the system clock. See the description of DTPS.</p> <p>Deadtime insert value = (DTPS × DTVVAL).</p> <p>DTVVAL selects the number of deadtime counts inserted as follows:</p> <p>When DTVVAL is 0, no counts are inserted.            When DTVVAL is 1, 1 count is inserted.            When DTVVAL is 2, 2 counts are inserted.</p> <p>This pattern continues up to a possible 63 counts.</p> <p>This field is write protected. It can be written only when MODE[WPDIS] = 1.</p>

### 12.2.3.16 FTM External Trigger (FTMx\_EXTTRIG)

This register:

- Indicates when a channel trigger was generated
- Enables the generation of a trigger when the FTM counter is equal to its initial value
- Selects which channels are used in the generation of the channel triggers

Several channels can be selected to generate multiple triggers in one PWM period. See [Channel trigger output](#) and [Initialization trigger](#).

Channels 6 and 7 are not used to generate channel triggers.

## Flextimer (FTM)

Address: Base address + 6Ch offset

### FTMx\_EXTTRIG field descriptions

Field	Description
0–23 Reserved	This field is reserved.
24 TRIGF	<p>Channel Trigger Flag</p> <p>Set by hardware when a channel trigger is generated. Clear TRIGF by reading EXTTRIG while TRIGF is set and then writing a 0 to TRIGF. Writing a 1 to TRIGF has no effect.</p> <p>If another channel trigger is generated before the clearing sequence is completed, the sequence is reset so TRIGF remains set after the clear sequence is completed for the earlier TRIGF.</p> <p>0 No channel trigger was generated. 1 A channel trigger was generated.</p>
25 INITTRIGEN	<p>Initialization Trigger Enable</p> <p>Enables the generation of the trigger when the FTM counter is equal to the CNTIN register.</p> <p>0 The generation of initialization trigger is disabled. 1 The generation of initialization trigger is enabled.</p>

Table continues on the next page...

## FTMx\_EXTTRIG field descriptions (continued)

Field	Description
26 CH1TRIG	Channel 1 Trigger Enable Enables the generation of the channel trigger when the FTM counter is equal to the CnV register. 0 The generation of the channel trigger is disabled. 1 The generation of the channel trigger is enabled.
27 CH0TRIG	Channel 0 Trigger Enable Enables the generation of the channel trigger when the FTM counter is equal to the CnV register. 0 The generation of the channel trigger is disabled. 1 The generation of the channel trigger is enabled.
28 CH5TRIG	Channel 5 Trigger Enable Enables the generation of the channel trigger when the FTM counter is equal to the CnV register. 0 The generation of the channel trigger is disabled. 1 The generation of the channel trigger is enabled.
29 CH4TRIG	Channel 4 Trigger Enable Enables the generation of the channel trigger when the FTM counter is equal to the CnV register. 0 The generation of the channel trigger is disabled. 1 The generation of the channel trigger is enabled.
30 CH3TRIG	Channel 3 Trigger Enable Enables the generation of the channel trigger when the FTM counter is equal to the CnV register. 0 The generation of the channel trigger is disabled. 1 The generation of the channel trigger is enabled.
31 CH2TRIG	Channel 2 Trigger Enable Enables the generation of the channel trigger when the FTM counter is equal to the CnV register. 0 The generation of the channel trigger is disabled. 1 The generation of the channel trigger is enabled.

## 12.2.3.17 Channels Polarity (FTMx\_POL)

This register defines the output polarity of the FTM channels.

**NOTE**

The safe value of a channel is the value of its POL bit.

Address: Base address + 70h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	Reserved															
W	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

## Flextimer (FTM)

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### FTMx\_POL field descriptions

Field	Description
0–23 Reserved	This field is reserved.
24 POL7	Channel 7 Polarity Defines the polarity of the channel output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel polarity is active high. 1 The channel polarity is active low.
25 POL6	Channel 6 Polarity Defines the polarity of the channel output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel polarity is active high. 1 The channel polarity is active low.
26 POL5	Channel 5 Polarity Defines the polarity of the channel output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel polarity is active high. 1 The channel polarity is active low.
27 POL4	Channel 4 Polarity Defines the polarity of the channel output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel polarity is active high. 1 The channel polarity is active low.
28 POL3	Channel 3 Polarity Defines the polarity of the channel output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel polarity is active high. 1 The channel polarity is active low.
29 POL2	Channel 2 Polarity Defines the polarity of the channel output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel polarity is active high. 1 The channel polarity is active low.

*Table continues on the next page...*

## FTMx\_POL field descriptions (continued)

Field	Description
30 POL1	<p>Channel 1 Polarity</p> <p>Defines the polarity of the channel output.</p> <p>This field is write protected. It can be written only when MODE[WPDIS] = 1.</p> <p>0 The channel polarity is active high. 1 The channel polarity is active low.</p>
31 POL0	<p>Channel 0 Polarity</p> <p>Defines the polarity of the channel output.</p> <p>This field is write protected. It can be written only when MODE[WPDIS] = 1.</p> <p>0 The channel polarity is active high. 1 The channel polarity is active low.</p>

## 12.2.3.18 Fault Mode Status (FTMx\_FMS)

This register contains the write protection enable bit.

Address: Base address + 74h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	
R	0																
W	[Shaded]																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	
Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

## FTMx\_FMS field descriptions

Field	Description
0–24 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
25 WPEN	<p>Write Protection Enable</p> <p>The WPEN bit is the negation of the WPDIS bit. WPEN is set when 1 is written to it. WPEN is cleared when WPEN bit is read as a 1 and then 1 is written to WPDIS. Writing 0 to WPEN has no effect.</p> <p>0 Write protection is disabled. Write protected bits can be written. 1 Write protection is enabled. Write protected bits cannot be written.</p>

Table continues on the next page...

**FTMx\_FMS field descriptions (continued)**

Field	Description
26–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

**12.2.3.19 Input Capture Filter Control (FTMx\_FILTER)**

This register selects the filter value for the inputs of channels.

Channels 4, 5, 6 and 7 do not have an input filter.

**NOTE**

Writing to the FILTER register has immediate effect and must be done only when the channels 0, 1, 2, and 3 are not in input modes. Failure to do this could result in a missing valid signal.

Address: Base address + 78h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

**FTMx\_FILTER field descriptions**

Field	Description
0–15 Reserved	This field is reserved.
16–19 CH3FVAL	Channel 3 Input Filter Selects the filter value for the channel input. The filter is disabled when the value is zero.
20–23 CH2FVAL	Channel 2 Input Filter Selects the filter value for the channel input. The filter is disabled when the value is zero.
24–27 CH1FVAL	Channel 1 Input Filter Selects the filter value for the channel input. The filter is disabled when the value is zero.
28–31 CH0FVAL	Channel 0 Input Filter Selects the filter value for the channel input. The filter is disabled when the value is zero.

### 12.2.3.20 Quadrature Decoder Control And Status (FTMx\_QDCTRL)

This register has the control and status bits for the Quadrature Decoder mode.

Address: Base address + 80h offset

**FTMx\_QDCTRL field descriptions**

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 PHAFLTREN	Phase A Input Filter Enable  Enables the filter for the quadrature decoder phase A input. The filter value for the phase A input is defined by the CH0FVAL field of FILTER. The phase A filter is also disabled when CH0FVAL is zero.  0 Phase A input filter is disabled. 1 Phase A input filter is enabled.

*Table continues on the next page...*

## FTMx\_QDCTRL field descriptions (continued)

Field	Description
25 PHBFLTREN	<p>Phase B Input Filter Enable</p> <p>Enables the filter for the quadrature decoder phase B input. The filter value for the phase B input is defined by the CH1FVAL field of FILTER. The phase B filter is also disabled when CH1FVAL is zero.</p> <p>0 Phase B input filter is disabled. 1 Phase B input filter is enabled.</p>
26 PHAPOL	<p>Phase A Input Polarity</p> <p>Selects the polarity for the quadrature decoder phase A input.</p> <p>0 Normal polarity. Phase A input signal is not inverted before identifying the rising and falling edges of this signal. 1 Inverted polarity. Phase A input signal is inverted before identifying the rising and falling edges of this signal.</p>
27 PHBPOL	<p>Phase B Input Polarity</p> <p>Selects the polarity for the quadrature decoder phase B input.</p> <p>0 Normal polarity. Phase B input signal is not inverted before identifying the rising and falling edges of this signal. 1 Inverted polarity. Phase B input signal is inverted before identifying the rising and falling edges of this signal.</p>
28 QUADMODE	<p>Quadrature Decoder Mode</p> <p>Selects the encoding mode used in the Quadrature Decoder mode.</p> <p>0 Phase A and phase B encoding mode. 1 Count and direction encoding mode.</p>
29 QUADIR	<p>FTM Counter Direction In Quadrature Decoder Mode</p> <p>Indicates the counting direction.</p> <p>0 Counting direction is decreasing (FTM counter decrement). 1 Counting direction is increasing (FTM counter increment).</p>
30 TOFDIR	<p>Timer Overflow Direction In Quadrature Decoder Mode</p> <p>Indicates if the TOF bit was set on the top or the bottom of counting.</p> <p>0 TOF bit was set on the bottom of counting. There was an FTM counter decrement and FTM counter changes from its minimum value (CNTIN register) to its maximum value (MOD register). 1 TOF bit was set on the top of counting. There was an FTM counter increment and FTM counter changes from its maximum value (MOD register) to its minimum value (CNTIN register).</p>
31 QUADEN	<p>Quadrature Decoder Mode Enable</p> <p>Enables the Quadrature Decoder mode. In this mode, the phase A and B input signals control the FTM counter direction. The Quadrature Decoder mode has precedence over the other modes. See <a href="#">Table 12-4</a>.</p> <p>This field is write protected. It can be written only when MODE[WPDIS] = 1.</p> <p>0 Quadrature Decoder mode is disabled. 1 Quadrature Decoder mode is enabled.</p>

### 12.2.3.21 Configuration (FTMx\_CONF)

This register selects the number of times that the FTM counter overflow should occur before the TOF bit to be set, the FTM behavior in BDM modes, the use of an external global time base, and the global time base signal generation.

Address: Base address + 84h offset

28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 CNTINC	CNTIN Register Synchronization 0 CNTIN register is updated with its buffer value at all rising edges of system clock. 1 CNTIN register is updated with its buffer value by the PWM synchronization.
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 HWTRIGMODE	Hardware Trigger Mode 0 FTM clears the TRIGj bit when the hardware trigger j is detected, where j = 0, 1,2. 1 FTM does not clear the TRIGj bit when the hardware trigger j is detected, where j = 0, 1,2.

**12.2.3.23 FTM Inverting Control (FTMx\_INVCTRL)**

This register controls when the channel (n) output becomes the channel (n+1) output, and channel (n+1) output becomes the channel (n) output. Each INVmEN bit enables the inverting operation for the corresponding pair channels m.

This register has a write buffer. The INVmEN bit is updated by the INVCTRL register synchronization.

## 12.2.3.24 FTM Software Output Control (FTMx\_SWOCTRL)

This register enables software control of channel (n) output and defines the value forced to the channel (n) output:

- The CHnOC bits enable the control of the corresponding channel (n) output by software.
- The CHnOCV bits select the value that is forced at the corresponding channel (n) output.

This register has a write buffer. The fields are updated by the SWOCTRL register synchronization.

31 CH0SEL	Channel 0 Select 0 Do not include the channel in the matching process. 1 Include the channel in the matching process.

## 12.2.4 Functional description

The notation used in this document to represent the counters and the generation of the signals is shown in the following figure.

Figure 12-6. Notation used

### 12.2.4.1 Clock source

The FTM has only one clock domain: the system clock.

#### 12.2.4.1.1 Counter clock source

The CLKS[1:0] bits in the SC register selects clock sources for the FTM counter or disables the FTM counter. After any chip reset, CLKS[1:0] = 0:0 so no clock source is selected.

The CLKS[1:0] bits may be read or written at any time. Disabling the FTM counter by writing 0:0 to the CLKS[1:0] bits does not affect the FTM counter value or other registers.

#### 12.2.4.2 Prescaler

The selected counter clock source passes through a prescaler that is a 7-bit counter. The value of the prescaler is selected by the PS[2:0] bits. The following figure shows an example of the prescaler counter and FTM counter.

Figure 12-7. Example of the prescaler counter

#### 12.2.4.3 Counter

The FTM has a 16-bit counter that is used by the channels either for input or output modes. The FTM counter clock is the selected clock divided by the prescaler.

The FTM counter has these modes of operation:

- [Up counting](#)
- [Up-down counting](#)
- [Quadrature Decoder mode](#)

### 12.2.4.3.1 Up counting

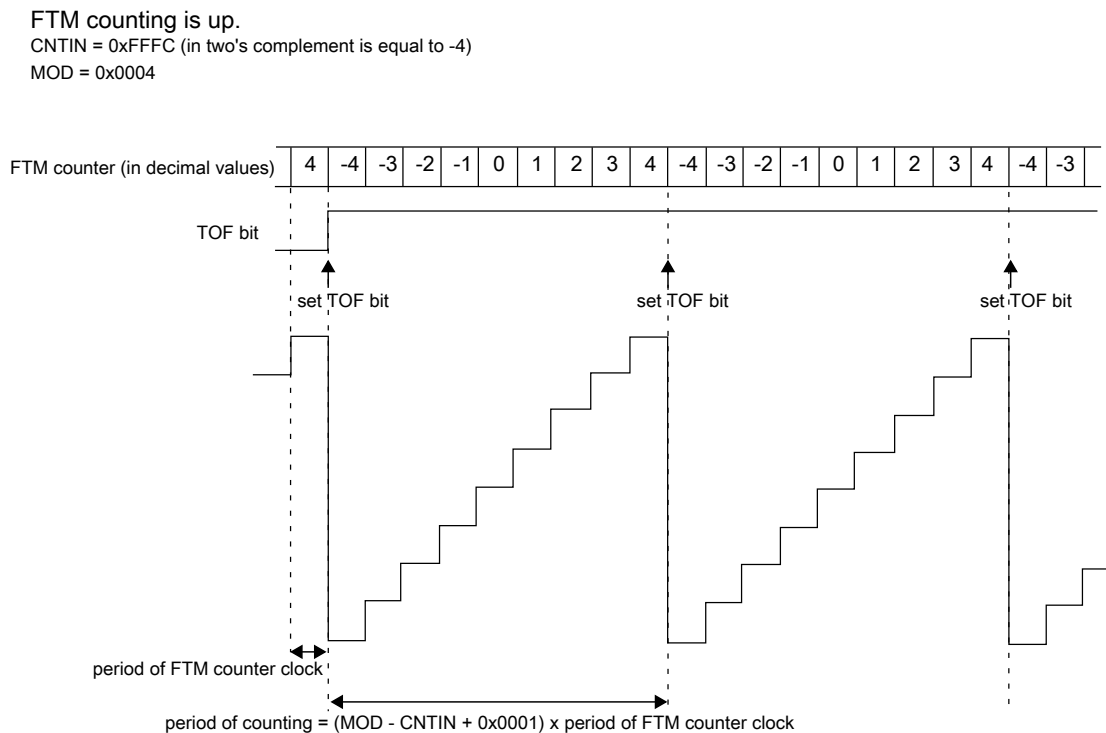

Up counting is selected when:

- QUADEN = 0, and
- CPWMS = 0

CNTIN defines the starting value of the count and MOD defines the final value of the count, see the following figure. The value of CNTIN is loaded into the FTM counter, and the counter increments until the value of MOD is reached, at which point the counter is reloaded with the value of CNTIN.

The FTM period when using up counting is  $(MOD - CNTIN + 0x0001) \times$  period of the FTM counter clock.

The TOF bit is set when the FTM counter changes from MOD to CNTIN.

**Figure 12-8. Example of FTM up and signed counting**

**Table 12-6. FTM counting based on CNTIN value**

When	Then
CNTIN = 0x0000	The FTM counting is equivalent to TPM up counting, that is, up and unsigned counting. See the following figure.
CNTIN[15] = 1	The initial value of the FTM counter is a negative number in two's complement, so the FTM counting is up and signed.

*Table continues on the next page...*

**Table 12-6. FTM counting based on CNTIN value (continued)**

When	Then
CNTIN[15] = 0 and CNTIN ≠ 0x0000	The initial value of the FTM counter is a positive number, so the FTM counting is up and unsigned.

FTM counting is up

CNTIN = 0x0000

MOD = 0x0004

**Figure 12-9. Example of FTM up counting with CNTIN = 0x0000**

**Note**

- FTM operation is only valid when the value of the CNTIN register is less than the value of the MOD register, either in the unsigned counting or signed counting. It is the responsibility of the software to ensure that the values in the CNTIN and MOD registers meet this requirement. Any values of CNTIN and MOD that do not satisfy this criteria can result in unpredictable behavior.
- MOD = CNTIN is a redundant condition. In this case, the FTM counter is always equal to MOD and the TOF bit is set in each rising edge of the FTM counter clock.

- When  $MOD = 0x0000$ ,  $CNTIN = 0x0000$ , for example after reset, and  $FTMEN = 1$ , the FTM counter remains stopped at  $0x0000$  until a non-zero value is written into the  $MOD$  or  $CNTIN$  registers.
- Setting  $CNTIN$  to be greater than the value of  $MOD$  is not recommended as this unusual setting may make the FTM operation difficult to comprehend. However, there is no restriction on this configuration, and an example is shown in the following figure.

**Figure 12-10. Example of up counting when the value of  $CNTIN$  is greater than the value of  $MOD$**

### 12.2.4.3.2 Up-down counting

Up-down counting is selected when:

- $QUADEN = 0$ , and
- $CPWMS = 1$

$CNTIN$  defines the starting value of the count and  $MOD$  defines the final value of the count. The value of  $CNTIN$  is loaded into the FTM counter, and the counter increments until the value of  $MOD$  is reached, at which point the counter is decremented until it returns to the value of  $CNTIN$  and the up-down counting restarts.

The FTM period when using up-down counting is  $2 \times (MOD - CNTIN) \times$  period of the FTM counter clock.

The TOF bit is set when the FTM counter changes from  $MOD$  to  $(MOD - 1)$ .

If ( $CNTIN = 0x0000$ ), the FTM counting is equivalent to TPM up-down counting, that is, up-down and unsigned counting. See the following figure.

## Flextimer (FTM)

FTM counting is up-down  
 CNTIN = 0x0000  
 MOD = 0x0004

**Figure 12-11. Example of up-down counting when CNTIN = 0x0000**

### Note

When CNTIN is different from zero in the up-down counting, a valid CPWM signal is generated:

- if  $C_nV > \text{CNTIN}$ , or
- if  $C_nV = 0$  or if  $C_nV[15] = 1$ . In this case, 0% CPWM is generated.

### 12.2.4.3.3 Free running counter

If (FTMEN = 0) and (MOD = 0x0000 or MOD = 0xFFFF), the FTM counter is a free running counter. In this case, the FTM counter runs free from 0x0000 through 0xFFFF and the TOF bit is set when the FTM counter changes from 0xFFFF to 0x0000. See the following figure.

**Figure 12-12. Example when the FTM counter is free running**

The FTM counter is also a free running counter when:

- FTMEN = 1

- QUADEN = 0
- CPWMS = 0
- CNTIN = 0x0000, and
- MOD = 0xFFFF

#### 12.2.4.3.4 Counter reset

Any one of the following cases resets the FTM counter to the value in the CNTIN register and the channels output to its initial value, except for channels in Output Compare mode.

- Any write to CNT.
- [FTM counter synchronization](#).
- A channel in Input Capture mode with ICRST = 1 ([FTM Counter Reset in Input Capture Mode](#)).

#### 12.2.4.3.5 When the TOF bit is set

The NUMTOF[4:0] bits define the number of times that the FTM counter overflow should occur before the TOF bit to be set. If NUMTOF[4:0] = 0x00, then the TOF bit is set at each FTM counter overflow.

Initialize the FTM counter, by writing to CNT, after writing to the NUMTOF[4:0] bits to avoid confusion about when the first counter overflow will occur.

Figure 12-13. Periodic TOF when NUMTOF = 0x02

Figure 12-14. Periodic TOF when NUMTOF = 0x00

## 12.2.4.4 Input Capture mode

The Input Capture mode is selected when:

- $DECAPEN = 0$
- $COMBINE = 0$
- $CPWMS = 0$
- $MSnB:MSnA = 0:0$ , and
- $ELSnB:ELSnA \neq 0:0$

When a selected edge occurs on the channel input, the current value of the FTM counter is captured into the CnV register, at the same time the CHnF bit is set and the channel interrupt is generated if enabled by CHnIE = 1. See the following figure.

When a channel is configured for input capture, the FTMxCHn pin is an edge-sensitive input. ELSnB:ELSnA control bits determine which edge, falling or rising, triggers input-capture event. Note that the maximum frequency for the channel input signal to be detected correctly is system clock divided by 4, which is required to meet Nyquist criteria for signal sampling.

Writes to the CnV register is ignored in Input Capture mode.

While in BDM, the input capture function works as configured. When a selected edge event occurs, the FTM counter value, which is frozen because of BDM, is captured into the CnV register and the CHnF bit is set.

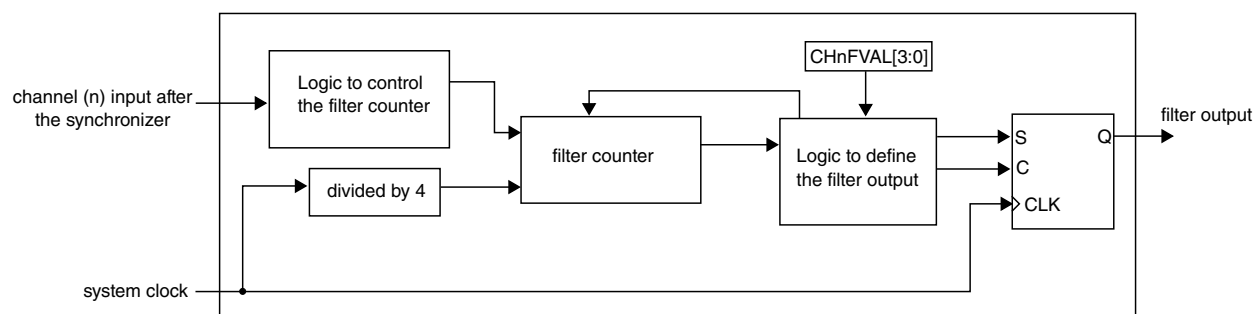

**Figure 12-15. Input Capture mode**

If the channel input does not have a filter enabled, then the input signal is always delayed 3 rising edges of the system clock, that is, two rising edges to the synchronizer plus one more rising edge to the edge detector. In other words, the CHnF bit is set on the third rising edge of the system clock after a valid edge occurs on the channel input.

#### 12.2.4.4.1 Filter for Input Capture mode

The filter function is only available on channels 0, 1, 2, and 3.

First, the input signal is synchronized by the system clock. Following synchronization, the input signal enters the filter block. See the following figure.

**Figure 12-16. Channel input filter**

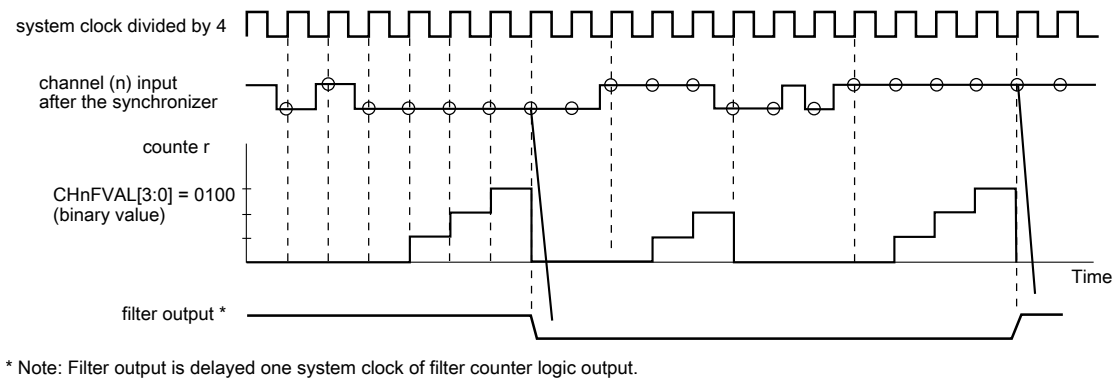

When there is a state change in the input signal, the counter is reset and starts counting up. As long as the new state is stable on the input, the counter continues to increment. When the counter is equal to CHnFVAL[3:0], the state change of the input signal is validated. It is then transmitted as a pulse edge to the edge detector.

If the opposite edge appears on the input signal before it can be validated, the counter is reset. At the next input transition, the counter starts counting again. Any pulse that is shorter than the minimum value selected by CHnFVAL[3:0] ( $\times 4$  system clocks) is regarded as a glitch and is not passed on to the edge detector. A timing diagram of the input filter is shown in the following figure.

The filter function is disabled when CHnFVAL[3:0] bits are zero. In this case, the input signal is delayed 3 rising edges of the system clock. If  $(\text{CHnFVAL}[3:0] \neq 0000)$ , then the input signal is delayed by the minimum pulse width ( $\text{CHnFVAL}[3:0] \times 4$  system clocks) plus a further 4 rising edges of the system clock: two rising edges to the synchronizer, one rising edge to the filter output, plus one more to the edge detector. In other words, CHnF is set  $(4 + 4 \times \text{CHnFVAL}[3:0])$  system clock periods after a valid edge occurs on the channel input.

The clock for the counter in the channel input filter is the system clock divided by 4.

## Flextimer (FTM)

**Figure 12-17. Channel input filter example**

The figure below shows an example of input capture with filter enabled and the delay added by each part of the input capture logic. Note that the input signal is delayed only by the synchronizer and edge detector logic if the filter is disabled.

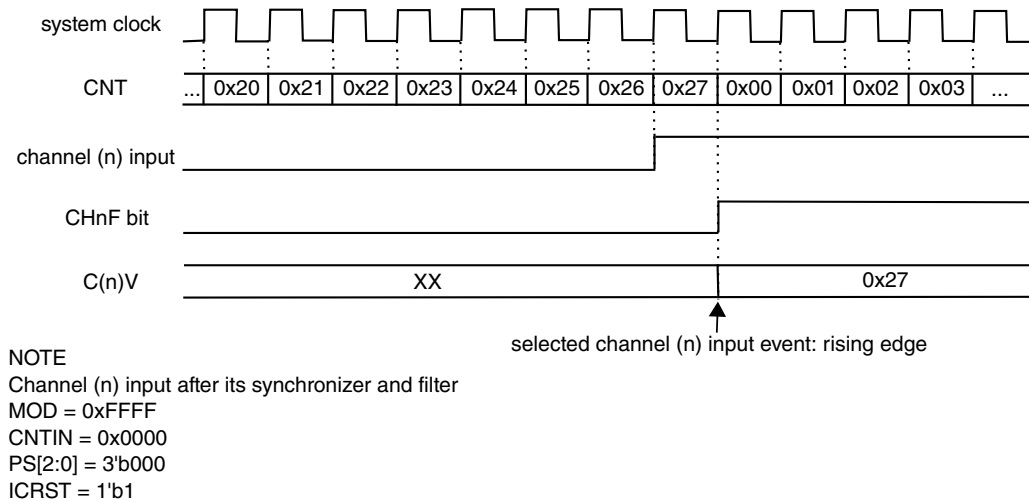

**Figure 12-18. Input capture example**

### 12.2.4.4.2 FTM Counter Reset in Input Capture Mode

If the channel (n) is in input capture mode and  $FTM_x\_CnSC$  [ICRST = 1], then when the selected input capture event occurs in the channel (n) input signal, the current value of the FTM counter is captured into the CnV register, the CHnF bit is set, the channel (n) interrupt is generated (if CHnIE = 1) and the FTM counter is reset to the CNTIN register value.

This allows the FTM to measure a period/pulse being applied to FTM\_CHn (counts of the FTM clock input) without having to implement a subtraction calculation in software subsequent to the event occurring.

The figure below shows the FTM counter reset when the selected input capture event is detected in a channel in input capture mode with  $ICRST = 1$ .

**Figure 12-19. Example of the Input Capture mode with  $ICRST = 1$**

### NOTE

- It is expected that the  $ICRST$  bit be set only when the channel is in input capture mode.
- In this case, if the FTM counter is reset, then the prescaler counter ([Prescaler](#)) and the TOF counter ([When the TOF bit is set](#)) also are reset.

### 12.2.4.5 Output Compare mode

The Output Compare mode is selected when:

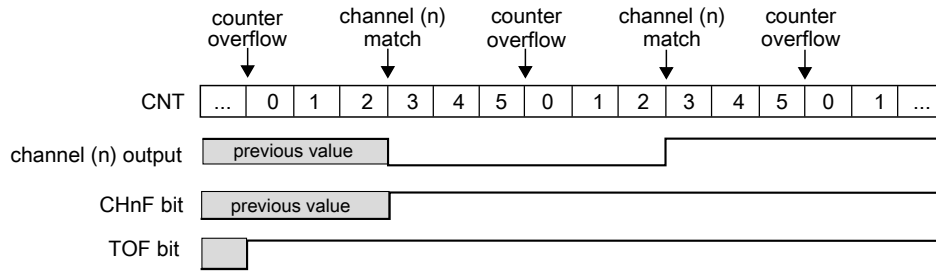

- $DECAPEN = 0$
- $COMBINE = 0$
- $CPWMS = 0$ , and
- $MSnB:MSnA = 0:1$

In Output Compare mode, the FTM can generate timed pulses with programmable position, polarity, duration, and frequency. When the counter matches the value in the  $CnV$  register of an output compare channel, the channel (n) output can be set, cleared, or toggled.

When a channel is initially configured to Toggle mode, the previous value of the channel output is held until the first output compare event occurs.

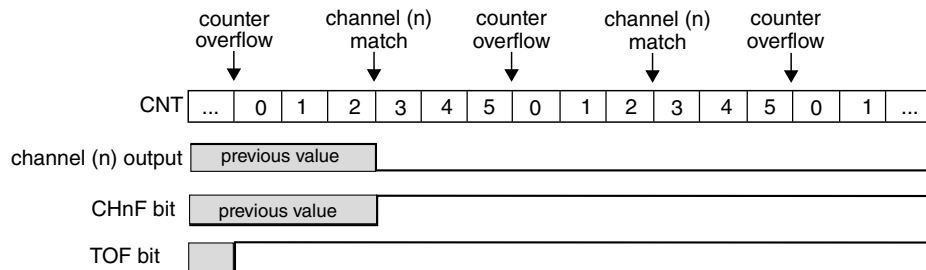

The CHnF bit is set and the channel (n) interrupt is generated if CHnIE = 1 at the channel (n) match (FTM counter = CnV).

MOD = 0x0005  
CnV = 0x0003

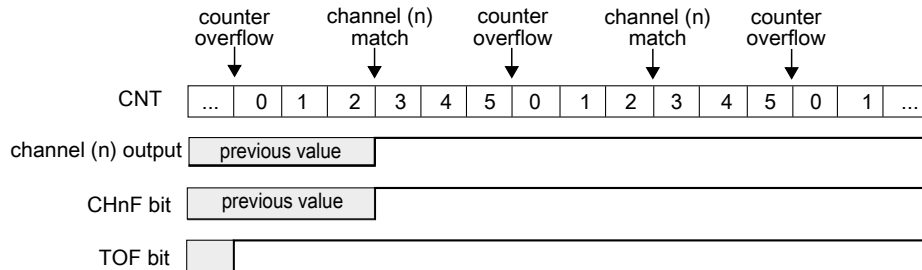

**Figure 12-20. Example of the Output Compare mode when the match toggles the channel output**

MOD = 0x0005  
CnV = 0x0003

**Figure 12-21. Example of the Output Compare mode when the match clears the channel output**

MOD = 0x0005  
CnV = 0x0003

**Figure 12-22. Example of the Output Compare mode when the match sets the channel output**

If (ELSnB:ELSnA = 0:0) when the counter reaches the value in the CnV register, the CHnF bit is set and the channel (n) interrupt is generated if CHnIE = 1, however the channel (n) output is not modified and controlled by FTM.

### 12.2.4.6 Edge-Aligned PWM (EPWM) mode

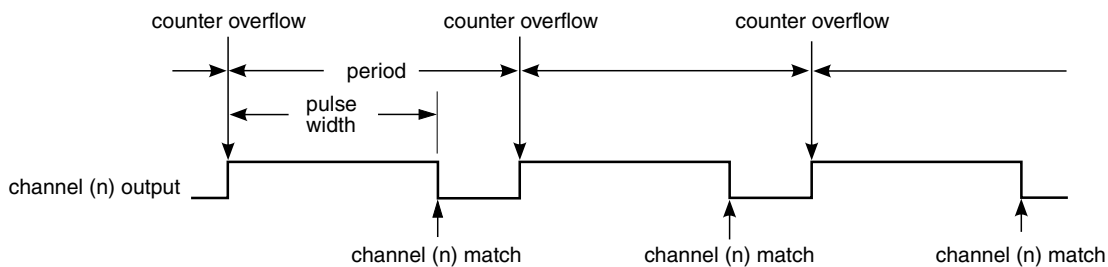

The Edge-Aligned mode is selected when:

- QUADEN = 0
- DECAPEN = 0
- COMBINE = 0
- CPWMS = 0, and
- MSnB = 1

The EPWM period is determined by  $(MOD - CNTIN + 0x0001)$  and the pulse width (duty cycle) is determined by  $(CnV - CNTIN)$ .

The CHnF bit is set and the channel (n) interrupt is generated if CHnIE = 1 at the channel (n) match (FTM counter = CnV), that is, at the end of the pulse width.

This type of PWM signal is called edge-aligned because the leading edges of all PWM signals are aligned with the beginning of the period, which is the same for all channels within an FTM.

**Figure 12-23. EPWM period and pulse width with ELSnB:ELSnA = 1:0**

If (ELSnB:ELSnA = 0:0) when the counter reaches the value in the CnV register, the CHnF bit is set and the channel (n) interrupt is generated if CHnIE = 1, however the channel (n) output is not controlled by FTM.

If (ELSnB:ELSnA = 1:0), then the channel (n) output is forced high at the counter overflow when the CNTIN register value is loaded into the FTM counter, and it is forced low at the channel (n) match (FTM counter = CnV). See the following figure.

**Figure 12-24. EPWM signal with ELSnB:ELSnA = 1:0**

If (ELSnB:ELSnA = X:1), then the channel (n) output is forced low at the counter overflow when the CNTIN register value is loaded into the FTM counter, and it is forced high at the channel (n) match (FTM counter = CnV). See the following figure.

**Figure 12-25. EPWM signal with ELSnB:ELSnA = X:1**

If (CnV = 0x0000), then the channel (n) output is a 0% duty cycle EPWM signal and CHnF bit is not set even when there is the channel (n) match.

If (CnV > MOD), then the channel (n) output is a 100% duty cycle EPWM signal and CHnF bit is not set. Therefore, MOD must be less than 0xFFFF in order to get a 100% duty cycle EPWM signal.

**Note**

When CNTIN is different from zero the following EPWM signals can be generated:

- 0% EPWM signal if CnV = CNTIN,
- EPWM signal between 0% and 100% if CNTIN < CnV <= MOD,
- 100% EPWM signal when CNTIN > CnV or CnV > MOD.

**12.2.4.7 Center-Aligned PWM (CPWM) mode**

The Center-Aligned mode is selected when:

- QUADEN = 0
- DECAPEN = 0
- COMBINE = 0, and
- CPWMS = 1

The CPWM pulse width (duty cycle) is determined by  $2 \times (CnV - CNTIN)$  and the period is determined by  $2 \times (MOD - CNTIN)$ . See the following figure. MOD must be kept in the range of 0x0001 to 0x7FFF because values outside this range can produce ambiguous results.

In the CPWM mode, the FTM counter counts up until it reaches MOD and then counts down until it reaches CNTIN.

The CHnF bit is set and channel (n) interrupt is generated (if CHnIE = 1) at the channel (n) match (FTM counter = CnV) when the FTM counting is down (at the begin of the pulse width) and when the FTM counting is up (at the end of the pulse width).

This type of PWM signal is called center-aligned because the pulse width centers for all channels are aligned with the value of CNTIN.

The other channel modes are not compatible with the up-down counter (CPWMS = 1). Therefore, all FTM channels must be used in CPWM mode when (CPWMS = 1).

**Figure 12-26. CPWM period and pulse width with ELSnB:ELSnA = 1:0**

If (ELSnB:ELSnA = 0:0) when the FTM counter reaches the value in the CnV register, the CHnF bit is set and the channel (n) interrupt is generated (if CHnIE = 1), however the channel (n) output is not controlled by FTM.

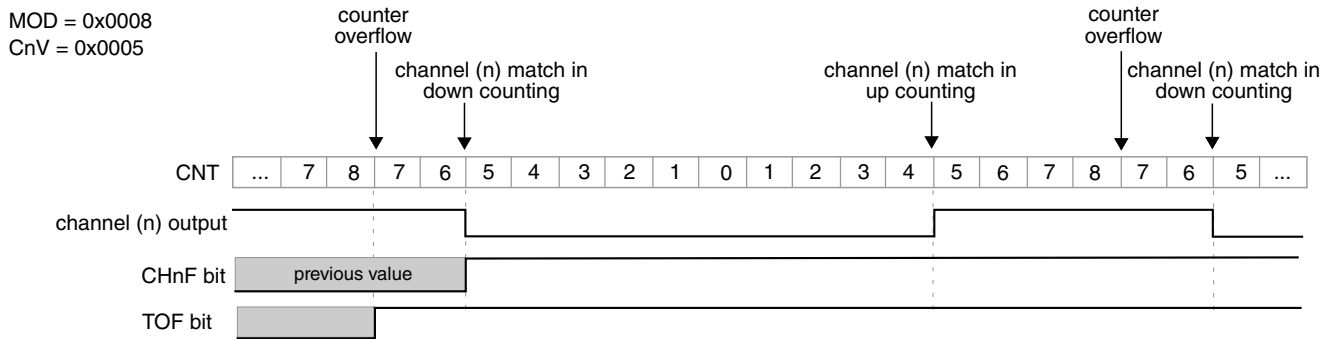

If (ELSnB:ELSnA = 1:0), then the channel (n) output is forced high at the channel (n) match (FTM counter = CnV) when counting down, and it is forced low at the channel (n) match when counting up. See the following figure.

**Figure 12-27. CPWM signal with ELSnB:ELSnA = 1:0**

## Flextimer (FTM)

If  $(ELSnB:ELSnA = X:1)$ , then the channel (n) output is forced low at the channel (n) match (FTM counter =  $CnV$ ) when counting down, and it is forced high at the channel (n) match when counting up. See the following figure.

**Figure 12-28. CPWM signal with  $ELSnB:ELSnA = X:1$**

If  $(CnV = 0x0000)$  or  $CnV$  is a negative value, that is  $(CnV[15] = 1)$ , then the channel (n) output is a 0% duty cycle CPWM signal and  $CHnF$  bit is not set even when there is the channel (n) match.

If  $CnV$  is a positive value, that is  $(CnV[15] = 0)$ ,  $(CnV \geq MOD)$ , and  $(MOD \neq 0x0000)$ , then the channel (n) output is a 100% duty cycle CPWM signal and  $CHnF$  bit is not set even when there is the channel (n) match. This implies that the usable range of periods set by  $MOD$  is  $0x0001$  through  $0x7FFE$ ,  $0x7FFF$  if you do not need to generate a 100% duty cycle CPWM signal. This is not a significant limitation because the resulting period is much longer than required for normal applications.

The CPWM mode must not be used when the FTM counter is a free running counter.

### 12.2.4.8 Combine mode

The Combine mode is selected when:

- $QUADEN = 0$
- $DECAPEN = 0$
- $COMBINE = 1$ , and
- $CPWMS = 0$

In Combine mode, an even channel (n) and adjacent odd channel (n+1) are combined to generate a PWM signal in the channel (n) output.

In the Combine mode, the PWM period is determined by  $(MOD - CNTIN + 0x0001)$  and the PWM pulse width (duty cycle) is determined by  $(IC(n+1)V - C(n)V)$ .

The CHnF bit is set and the channel (n) interrupt is generated (if CHnIE = 1) at the channel (n) match (FTM counter = C(n)V). The CH(n+1)F bit is set and the channel (n+1) interrupt is generated, if CH(n+1)IE = 1, at the channel (n+1) match (FTM counter = C(n+1)V).

If (ELSnB:ELSnA = 1:0), then the channel (n) output is forced low at the beginning of the period (FTM counter = CNTIN) and at the channel (n+1) match (FTM counter = C(n+1)V). It is forced high at the channel (n) match (FTM counter = C(n)V). See the following figure.

If (ELSnB:ELSnA = X:1), then the channel (n) output is forced high at the beginning of the period (FTM counter = CNTIN) and at the channel (n+1) match (FTM counter = C(n+1)V). It is forced low at the channel (n) match (FTM counter = C(n)V). See the following figure.

In Combine mode, the ELS(n+1)B and ELS(n+1)A bits are not used in the generation of the channels (n) and (n+1) output. However, if (ELSnB:ELSnA = 0:0) then the channel (n) output is not controlled by FTM, and if (ELSnB:ELSnA = 0:0) then the channel (n+1) output is not controlled by FTM.

**Figure 12-29. Combine mode**

The following figures illustrate the PWM signals generation using Combine mode.

**Figure 12-30. Channel (n) output if  $(CNTIN < C(n)V < MOD)$  and  $(CNTIN < C(n+1)V < MOD)$  and  $(C(n)V < C(n+1)V)$**

**Figure 12-31. Channel (n) output if  $(CNTIN < C(n)V < MOD)$  and  $(C(n+1)V = MOD)$**

**Figure 12-32. Channel (n) output if  $(C(n)V = CNTIN)$  and  $(CNTIN < C(n+1)V < MOD)$**

**Figure 12-33. Channel (n) output if  $(CNTIN < C(n)V < MOD)$  and  $(C(n)V$  is Almost Equal to  $CNTIN$ ) and  $(C(n+1)V = MOD)$**

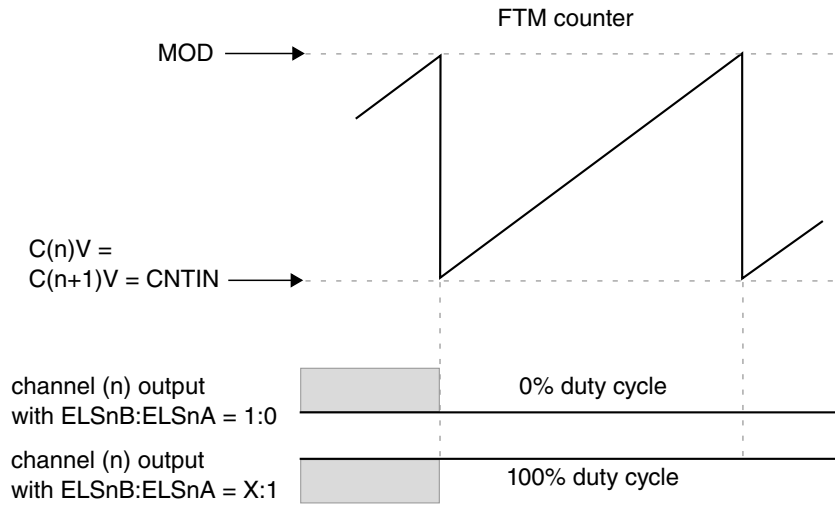

**Figure 12-34. Channel (n) output if  $(C(n)V = CNTIN)$  and  $(CNTIN < C(n+1)V < MOD)$  and  $(C(n+1)V$  is Almost Equal to  $MOD$ )**

**Figure 12-35. Channel (n) output if  $C(n)V$  and  $C(n+1)V$  are not between  $CNTIN$  and  $MOD$**

**Figure 12-36. Channel (n) output if  $(CNTIN < C(n)V < MOD)$  and  $(CNTIN < C(n+1)V < MOD)$  and  $(C(n)V = C(n+1)V)$**

**Figure 12-37. Channel (n) output if  $(C(n)V = C(n+1)V = CNTIN)$**

**Figure 12-38. Channel (n) output if  $(C(n)V = C(n+1)V = MOD)$**

**Figure 12-39. Channel (n) output if  $(CNTIN < C(n)V < MOD)$  and  $(CNTIN < C(n+1)V < MOD)$  and  $(C(n)V > C(n+1)V)$**

Figure 12-40. Channel (n) output if  $(C(n)V < CNTIN)$  and  $(CNTIN < C(n+1)V < MOD)$

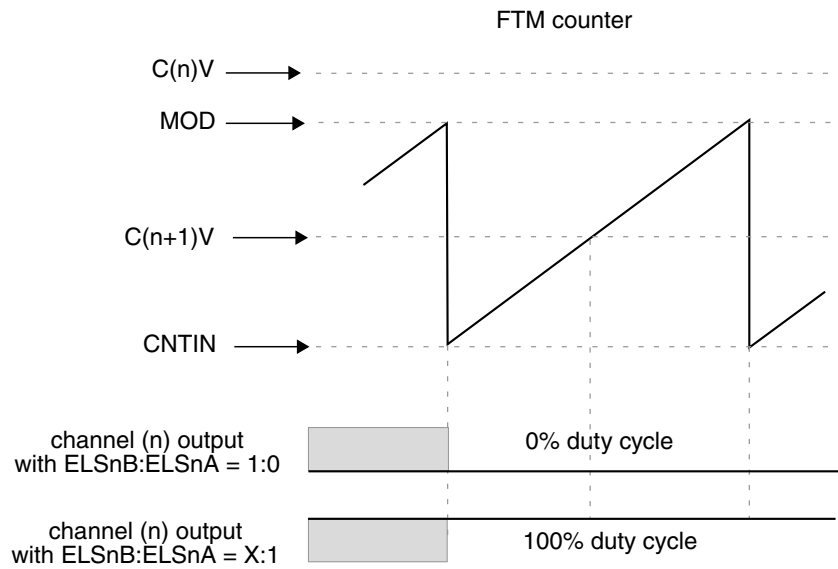

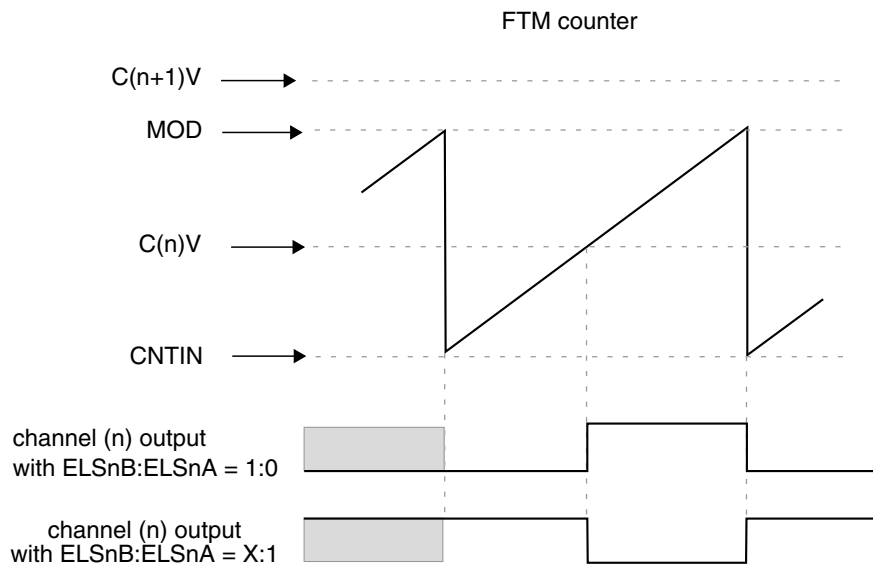

Figure 12-41. Channel (n) output if  $(C(n+1)V < CNTIN)$  and  $(CNTIN < C(n)V < MOD)$

**Figure 12-42. Channel (n) output if  $(C(n)V > MOD)$  and  $(CNTIN < C(n+1)V < MOD)$**

**Figure 12-43. Channel (n) output if  $(C(n+1)V > MOD)$  and  $(CNTIN < C(n)V < MOD)$**

**Figure 12-44. Channel (n) output if  $(C(n+1)V > MOD$  and  $(CNTIN < C(n)V = MOD$ )**

### 12.2.4.8.1 Asymmetrical PWM

In Combine mode, the control of the PWM signal first edge, when the channel (n) match occurs, that is, FTM counter =  $C(n)V$ , is independent of the control of the PWM signal second edge, when the channel (n+1) match occurs, that is, FTM counter =  $C(n+1)V$ . So, Combine mode allows the generation of asymmetrical PWM signals.

### 12.2.4.9 Complementary mode

The Complementary mode is selected when:

- $QUADEN = 0$
- $DECAPEN = 0$
- $COMP = 1$

In Complementary mode, the channel (n+1) output is the inverse of the channel (n) output.

So, the channel (n+1) output is the same as the channel (n) output when:

- $QUADEN = 0$
- $DECAPEN = 0$
- $COMP = 0$

**Figure 12-45. Channel (n+1) output in Complementary mode with  $(ELSnB:ELSnA = 1:0)$**

**Figure 12-46. Channel (n+1) output in Complementary mode with  $(ELSnB:ELSnA = X:1)$**

### NOTE

The complementary mode is not available in Output Compare mode.

## 12.2.4.10 Registers updated from write buffers

### 12.2.4.10.1 CNTIN register update

The following table describes when CNTIN register is updated:

**Table 12-7. CNTIN register update**

When	Then CNTIN register is updated
$CLKS[1:0] = 0:0$	When CNTIN register is written, independent of FTMEN bit.
<ul style="list-style-type: none"> <li>FTMEN = 0, or</li> <li>CNTINC = 0</li> </ul>	At the next system clock after CNTIN was written.
<ul style="list-style-type: none"> <li>FTMEN = 1,</li> <li>SYNCMODE = 1, and</li> <li>CNTINC = 1</li> </ul>	By the <a href="#">CNTIN register synchronization</a> .

### 12.2.4.10.2 MOD register update

The following table describes when MOD register is updated:

**Table 12-8. MOD register update**

When	Then MOD register is updated
CLKS[1:0] = 0:0	When MOD register is written, independent of FTMEN bit.
<ul style="list-style-type: none"> <li>• CLKS[1:0] ≠ 0:0, and</li> <li>• FTMEN = 0</li> </ul>	According to the CPWMS bit, that is: <ul style="list-style-type: none"> <li>• If the selected mode is not CPWM then MOD register is updated after MOD register was written and the FTM counter changes from MOD to CNTIN. If the FTM counter is at free-running counter mode then this update occurs when the FTM counter changes from 0xFFFF to 0x0000.</li> <li>• If the selected mode is CPWM then MOD register is updated after MOD register was written and the FTM counter changes from MOD to (MOD – 0x0001).</li> </ul>
<ul style="list-style-type: none"> <li>• CLKS[1:0] ≠ 0:0, and</li> <li>• FTMEN = 1</li> </ul>	By the <a href="#">MOD register synchronization</a> .

### 12.2.4.10.3 CnV register update

The following table describes when CnV register is updated:

**Table 12-9. CnV register update**

When	Then CnV register is updated
CLKS[1:0] = 0:0	When CnV register is written, independent of FTMEN bit.
<ul style="list-style-type: none"> <li>• CLKS[1:0] ≠ 0:0, and</li> <li>• FTMEN = 0</li> </ul>	According to the selected mode, that is: <ul style="list-style-type: none"> <li>• If the selected mode is Output Compare, then CnV register is updated on the next FTM counter change, end of the prescaler counting, after CnV register was written.</li> <li>• If the selected mode is EPWM, then CnV register is updated after CnV register was written and the FTM counter changes from MOD to CNTIN. If the FTM counter is at free-running counter mode then this update occurs when the FTM counter changes from 0xFFFF to 0x0000.</li> <li>• If the selected mode is CPWM, then CnV register is updated after CnV register was written and the FTM counter changes from MOD to (MOD – 0x0001).</li> </ul>
<ul style="list-style-type: none"> <li>• CLKS[1:0] ≠ 0:0, and</li> <li>• FTMEN = 1</li> </ul>	According to the selected mode, that is: <ul style="list-style-type: none"> <li>• If the selected mode is output compare then CnV register is updated according to the SYNCEN bit. If (SYNCEN = 0) then CnV register is updated after CnV register was written at the next change of the FTM counter, the end of the prescaler counting. If (SYNCEN = 1) then CnV register is updated by the <a href="#">C(n)V and C(n+1)V register synchronization</a>.</li> <li>• If the selected mode is not output compare and (SYNCEN = 1) then CnV register is updated by the <a href="#">C(n)V and C(n+1)V register synchronization</a>.</li> </ul>

### 12.2.4.11 PWM synchronization

The PWM synchronization provides an opportunity to update the MOD, CNTIN, CnV, OUTMASK, INVCTRL and SWOCTRL registers with their buffered value and force the FTM counter to the CNTIN register value.

#### Note

The legacy PWM synchronization ( $\text{SYNCMODE} = 0$ ) is a subset of the enhanced PWM synchronization ( $\text{SYNCMODE} = 1$ ). Thus, only the enhanced PWM synchronization must be used.

#### 12.2.4.11.1 Hardware trigger

Three hardware trigger signal inputs of the FTM module are enabled when  $\text{TRIGN} = 1$ , where  $n = 0, 1$  or  $2$  corresponding to each one of the input signals, respectively. The hardware trigger input  $n$  is synchronized by the system clock. The PWM synchronization with hardware trigger is initiated when a rising edge is detected at the enabled hardware trigger inputs.

If ( $\text{HWTRIGMODE} = 0$ ) then the  $\text{TRIGN}$  bit is cleared when  $0$  is written to it or when the trigger  $n$  event is detected.

In this case, if two or more hardware triggers are enabled (for example,  $\text{TRIG0}$  and  $\text{TRIG1} = 1$ ) and only trigger 1 event occurs, then only  $\text{TRIG1}$  bit is cleared. If a trigger  $n$  event occurs together with a write setting  $\text{TRIGN}$  bit, then the synchronization is initiated, but  $\text{TRIGN}$  bit remains set due to the write operation.

Note  
All hardware trigger inputs have the same behavior.

**Figure 12-47. Hardware trigger event with  $\text{HWTRIGMODE} = 0$**

If HWTRIGMODE = 1, then the TRIGn bit is only cleared when 0 is written to it.

### NOTE

The HWTRIGMODE bit must be 1 only with enhanced PWM synchronization (SYNCMODE = 1).

#### 12.2.4.11.2 Software trigger

A software trigger event occurs when 1 is written to the SYNC[SWSYNC] bit. The SWSYNC bit is cleared when 0 is written to it or when the PWM synchronization, initiated by the software event, is completed.

If another software trigger event occurs (by writing another 1 to the SWSYNC bit) at the same time the PWM synchronization initiated by the previous software trigger event is ending, a new PWM synchronization is started and the SWSYNC bit remains equal to 1.

If SYNCMODE = 0 then the SWSYNC bit is also cleared by FTM according to PWMSYNC and REINIT bits. In this case if (PWMSYNC = 1) or (PWMSYNC = 0 and REINIT = 0) then SWSYNC bit is cleared at the next selected loading point after that the software trigger event occurred; see [Boundary cycle and loading points](#) and the following figure. If (PWMSYNC = 0) and (REINIT = 1) then SWSYNC bit is cleared when the software trigger event occurs.

If SYNCMODE = 1 then the SWSYNC bit is also cleared by FTM according to the SWRSTCNT bit. If SWRSTCNT = 0 then SWSYNC bit is cleared at the next selected loading point after that the software trigger event occurred; see the following figure. If SWRSTCNT = 1 then SWSYNC bit is cleared when the software trigger event occurs.

Figure 12-48. Software trigger event

#### 12.2.4.11.3 Boundary cycle and loading points

The boundary cycle definition is important for the loading points for the registers MOD, CNTIN, and C(n)V.

In **Up counting** mode, the boundary cycle is defined as when the counter wraps to its initial value (CNTIN). If in **Up-down counting** mode, then the boundary cycle is defined as when the counter turns from down to up counting and when from up to down counting.

The following figure shows the boundary cycles and the loading points for the registers. In the Up Counting mode, the loading points are enabled if one of CNTMIN or CTMAX bits are 1. In the Up-Down Counting mode, the loading points are selected by CNTMIN and CNTMAX bits, as indicated in the figure. These loading points are safe places for register updates thus allowing a smooth transitions in PWM waveform generation.

For both counting modes, if neither CNTMIN nor CNTMAX are 1, then the boundary cycles are not used as loading points for registers updates. See the register synchronization descriptions in the following sections for details.

**Figure 12-49. Boundary cycles and loading points**

#### 12.2.4.11.4 MOD register synchronization

The MOD register synchronization updates the MOD register with its buffer value. This synchronization is enabled if (FTMEN = 1).

The MOD register synchronization can be done by either the enhanced PWM synchronization (SYNCMODE = 1) or the legacy PWM synchronization (SYNCMODE = 0). However, it is expected that the MOD register be synchronized only by the enhanced PWM synchronization.

In the case of enhanced PWM synchronization, the MOD register synchronization depends on SWWRBUF, SWRSTCNT, HWWRBUF, and HWRSTCNT bits according to this flowchart:

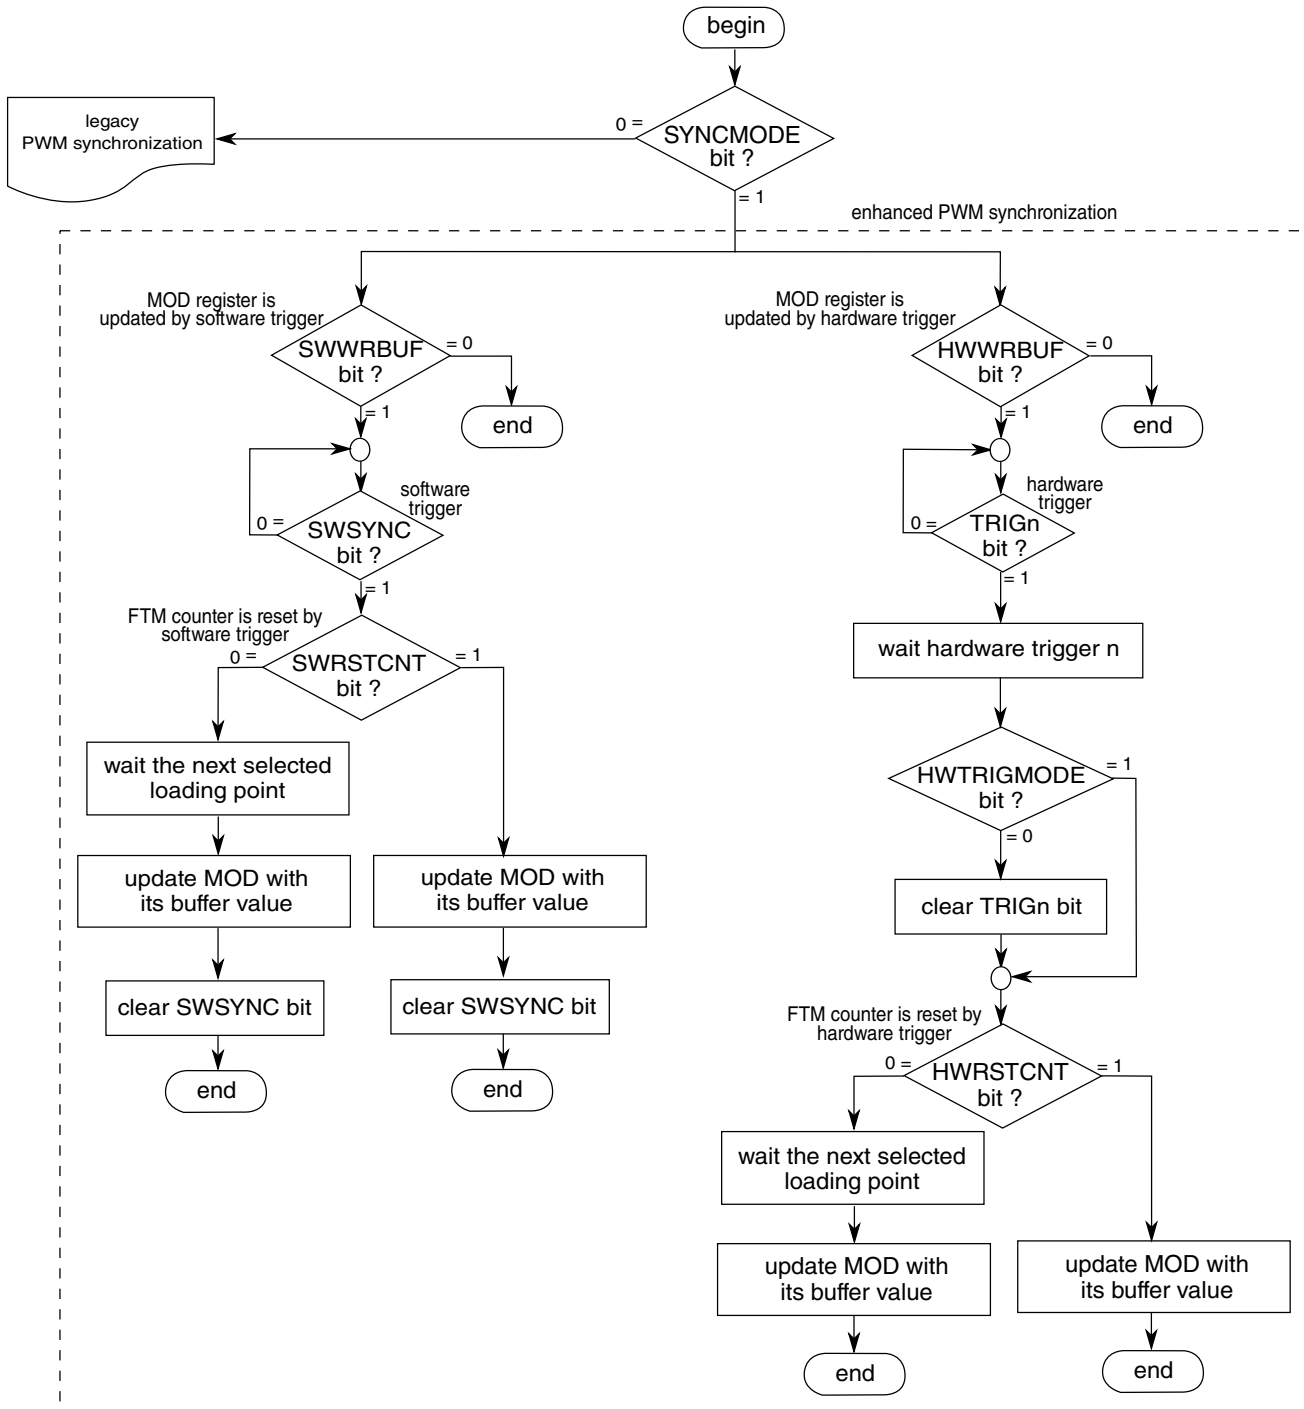

Figure 12-50. MOD register synchronization flowchart

In the case of legacy PWM synchronization, the MOD register synchronization depends on PWMSYNC and REINIT bits according to the following description.

If ( $\text{SYNCMODE} = 0$ ), ( $\text{PWMSYNC} = 0$ ), and ( $\text{REINIT} = 0$ ), then this synchronization is made on the next selected loading point after an enabled trigger event takes place. If the trigger event was a software trigger, then the  $\text{SWSYNC}$  bit is cleared on the next selected loading point. If the trigger event was a hardware trigger, then the trigger enable bit ( $\text{TRIGn}$ ) is cleared according to [Hardware trigger](#). Examples with software and hardware triggers follow.

**Figure 12-51. MOD synchronization with ( $\text{SYNCMODE} = 0$ ), ( $\text{PWMSYNC} = 0$ ), ( $\text{REINIT} = 0$ ), and software trigger was used**

**Figure 12-52. MOD synchronization with ( $\text{SYNCMODE} = 0$ ), ( $\text{HWTRIGMODE} = 0$ ), ( $\text{PWMSYNC} = 0$ ), ( $\text{REINIT} = 0$ ), and a hardware trigger was used**

If ( $\text{SYNCMODE} = 0$ ), ( $\text{PWMSYNC} = 0$ ), and ( $\text{REINIT} = 1$ ), then this synchronization is made on the next enabled trigger event. If the trigger event was a software trigger, then the  $\text{SWSYNC}$  bit is cleared according to the following example. If the trigger event was a hardware trigger, then the  $\text{TRIGn}$  bit is cleared according to [Hardware trigger](#). Examples with software and hardware triggers follow.

**Figure 12-53. MOD synchronization with (SYNCMODE = 0), (PWMSYNC = 0), (REINIT = 1), and software trigger was used**

**Figure 12-54. MOD synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (PWMSYNC = 0), (REINIT = 1), and a hardware trigger was used**

If (SYNCMODE = 0) and (PWMSYNC = 1), then this synchronization is made on the next selected loading point after the software trigger event takes place. The SWSYNC bit is cleared on the next selected loading point:

**Figure 12-55. MOD synchronization with (SYNCMODE = 0) and (PWMSYNC = 1)**

### 12.2.4.11.5 CNTIN register synchronization

The CNTIN register synchronization updates the CNTIN register with its buffer value.

This synchronization is enabled if (FTMEN = 1), (SYNCMODE = 1), and (CNTINC = 1). The CNTIN register synchronization can be done only by the enhanced PWM synchronization (SYNCMODE = 1). The synchronization mechanism is the same as the MOD register synchronization done by the enhanced PWM synchronization; see [MOD register synchronization](#).

### 12.2.4.11.6 C(n)V and C(n+1)V register synchronization

The C(n)V and C(n+1)V registers synchronization updates the C(n)V and C(n+1)V registers with their buffer values.

This synchronization is enabled if (FTMEN = 1) and (SYNCEN = 1). The synchronization mechanism is the same as the [MOD register synchronization](#). However, it is expected that the C(n)V and C(n+1)V registers be synchronized only by the enhanced PWM synchronization (SYNCMODE = 1).

### 12.2.4.11.7 OUTMASK register synchronization

The OUTMASK register synchronization updates the OUTMASK register with its buffer value.

The OUTMASK register can be updated at each rising edge of system clock (SYNCHOM = 0), by the enhanced PWM synchronization (SYNCHOM = 1 and SYNCMODE = 1) or by the legacy PWM synchronization (SYNCHOM = 1 and SYNCMODE = 0). However, it is expected that the OUTMASK register be synchronized only by the enhanced PWM synchronization.

In the case of enhanced PWM synchronization, the OUTMASK register synchronization depends on SWOM and HWOM bits. See the following flowchart:

Figure 12-56. OUTMASK register synchronization flowchart

In the case of legacy PWM synchronization, the OUTMASK register synchronization depends on PWMSYNC bit according to the following description.

If ( $\text{SYNCMODE} = 0$ ), ( $\text{SYNCHOM} = 1$ ), and ( $\text{PWMSYNC} = 0$ ), then this synchronization is done on the next enabled trigger event. If the trigger event was a software trigger, then the  $\text{SWSYNC}$  bit is cleared on the next selected loading point. If the trigger event was a hardware trigger, then the  $\text{TRIGn}$  bit is cleared according to [Hardware trigger](#). Examples with software and hardware triggers follow.

**Figure 12-57. OUTMASK synchronization with ( $\text{SYNCMODE} = 0$ ), ( $\text{SYNCHOM} = 1$ ), ( $\text{PWMSYNC} = 0$ ) and software trigger was used**

**Figure 12-58. OUTMASK synchronization with ( $\text{SYNCMODE} = 0$ ), ( $\text{HWTRIGMODE} = 0$ ), ( $\text{SYNCHOM} = 1$ ), ( $\text{PWMSYNC} = 0$ ), and a hardware trigger was used**

If ( $\text{SYNCMODE} = 0$ ), ( $\text{SYNCHOM} = 1$ ), and ( $\text{PWMSYNC} = 1$ ), then this synchronization is made on the next enabled hardware trigger. The  $\text{TRIGn}$  bit is cleared according to [Hardware trigger](#). An example with a hardware trigger follows.

**Figure 12-59. OUTMASK synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (SYNCHOM = 1), (PWMSYNC = 1), and a hardware trigger was used**

### 12.2.4.11.8 INVCTRL register synchronization

The INVCTRL register synchronization updates the INVCTRL register with its buffer value.

The INVCTRL register can be updated at each rising edge of system clock (INVC = 0) or by the enhanced PWM synchronization (INVC = 1 and SYNCMODE = 1) according to the following flowchart.

In the case of enhanced PWM synchronization, the INVCTRL register synchronization depends on SWINVC and HWINVC bits.

Figure 12-60. INVCTRL register synchronization flowchart

### 12.2.4.11.9 SWOCTRL register synchronization

The SWOCTRL register synchronization updates the SWOCTRL register with its buffer value.

The SWOCTRL register can be updated at each rising edge of system clock (SWOC = 0) or by the enhanced PWM synchronization (SWOC = 1 and SYNCMODE = 1) according to the following flowchart.

In the case of enhanced PWM synchronization, the SWOCTRL register synchronization depends on SWSOC and HWSOC bits.

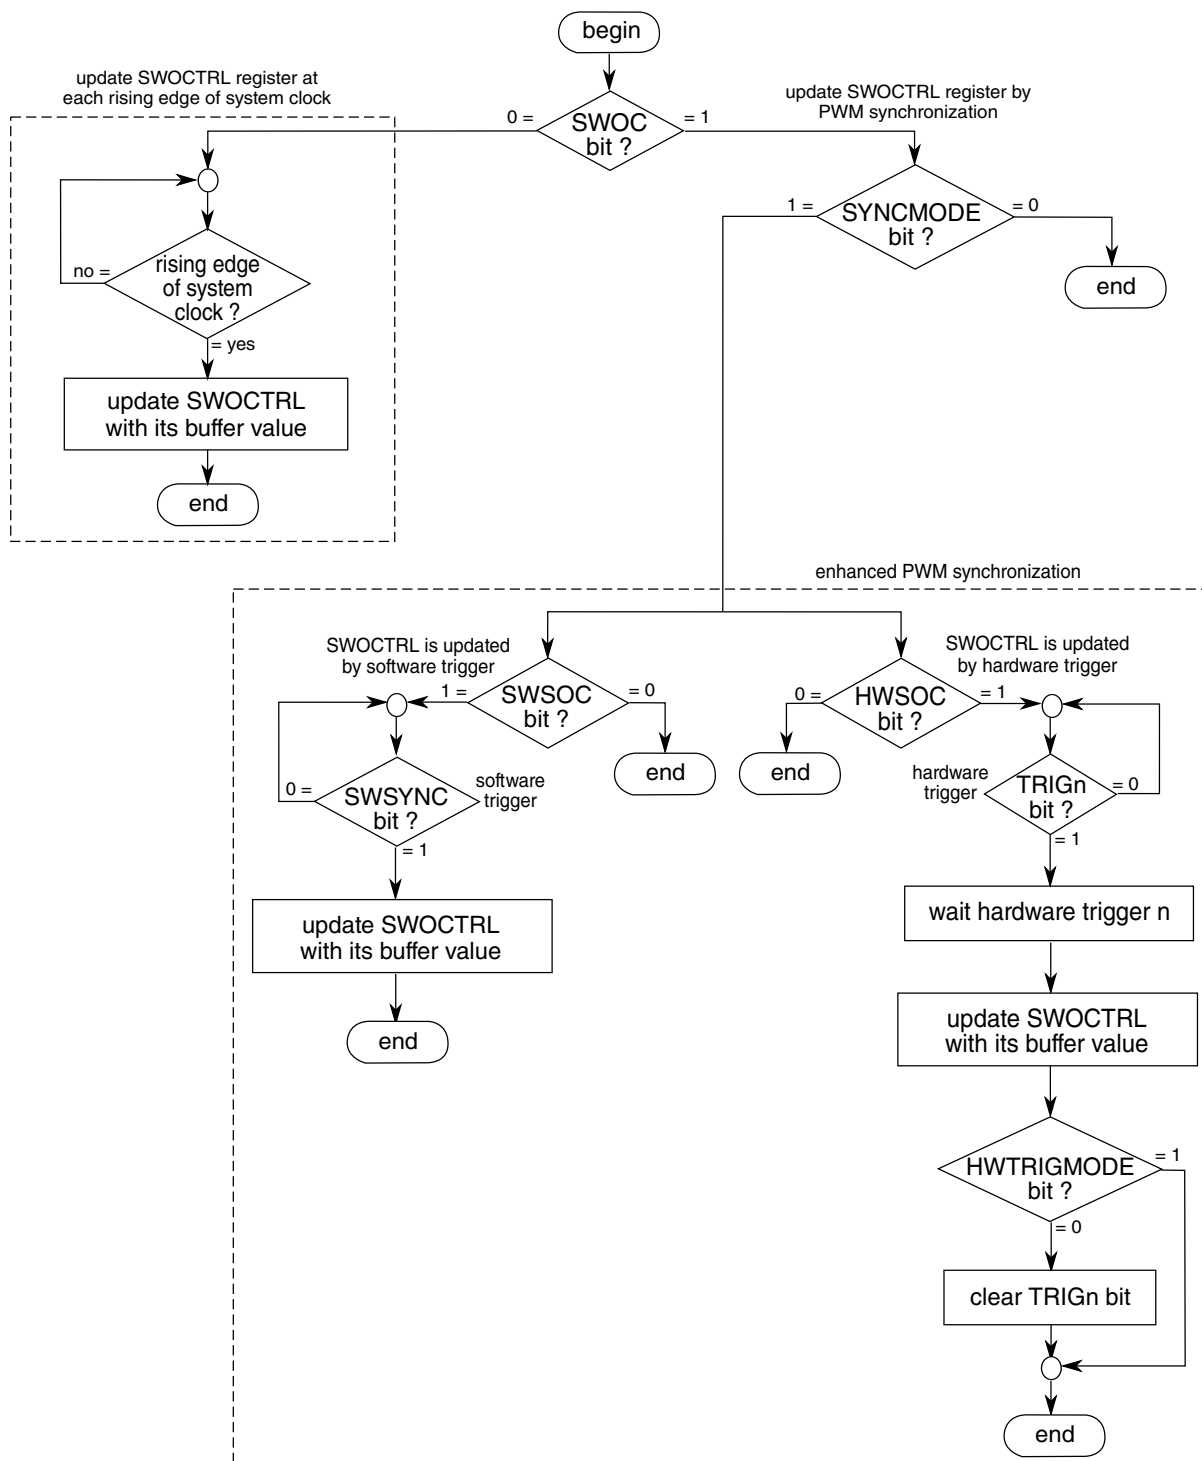

Figure 12-61. SWOCTRL register synchronization flowchart

### 12.2.4.11.10 FTM counter synchronization

The FTM counter synchronization is a mechanism that allows the FTM to restart the PWM generation at a certain point in the PWM period. The channels outputs are forced to their initial value, except for channels in Output Compare mode, and the FTM counter is forced to its initial counting value defined by CNTIN register.

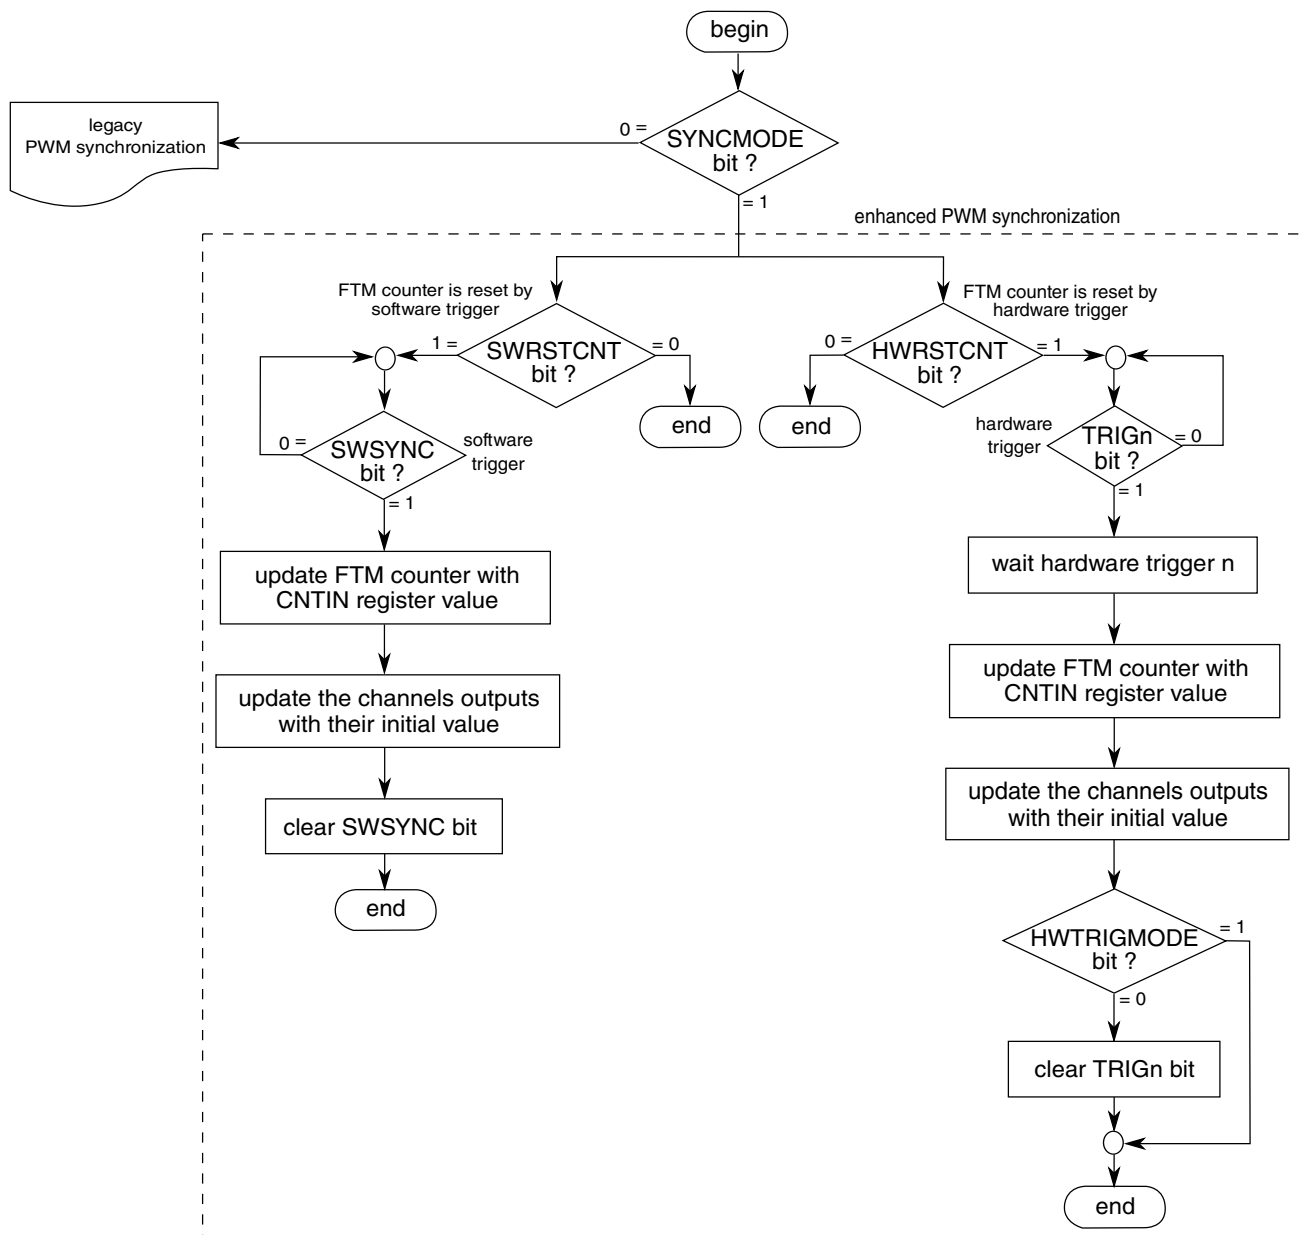

The following figure shows the FTM counter synchronization. Note that after the synchronization event occurs, the channel (n) is set to its initial value and the channel (n+1) is not set to its initial value due to a specific timing of this figure in which the deadtime insertion prevents this channel output from transitioning to 1. If no deadtime insertion is selected, then the channel (n+1) transitions to logical value 1 immediately after the synchronization event occurs.

**Figure 12-62. FTM counter synchronization**

The FTM counter synchronization can be done by either the enhanced PWM synchronization ( $\text{SYNCMODE} = 1$ ) or the legacy PWM synchronization ( $\text{SYNCMODE} = 0$ ). However, the FTM counter must be synchronized only by the enhanced PWM synchronization.

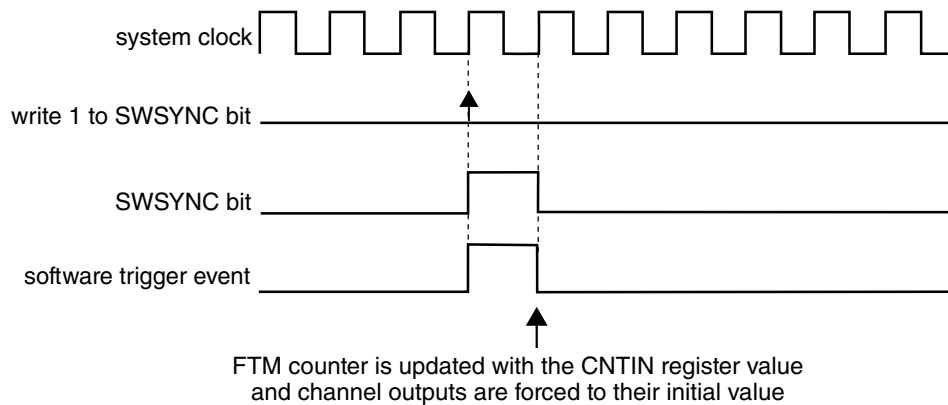

In the case of enhanced PWM synchronization, the FTM counter synchronization depends on  $\text{SWRSTCNT}$  and  $\text{HWRSTCNT}$  bits according to the following flowchart.

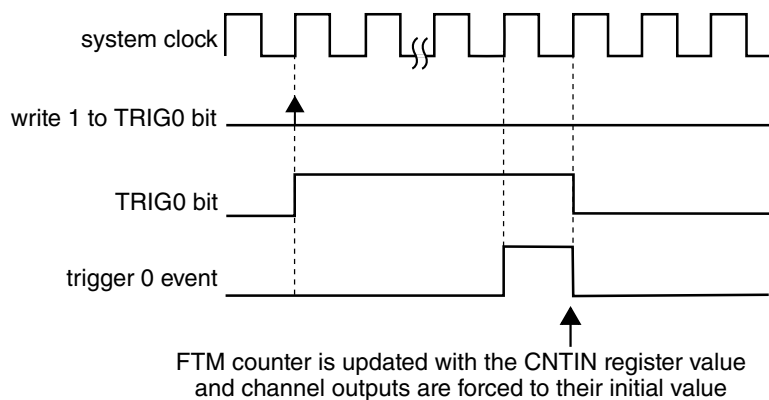

**Figure 12-63. FTM counter synchronization flowchart**

In the case of legacy PWM synchronization, the FTM counter synchronization depends on REINIT and PWMSYNC bits according to the following description.

If (SYNCMODE = 0), (REINIT = 1), and (PWMSYNC = 0) then this synchronization is made on the next enabled trigger event. If the trigger event was a software trigger then the SWSYNC bit is cleared according to the following example. If the trigger event was a hardware trigger then the TRIGn bit is cleared according to [Hardware trigger](#). Examples with software and hardware triggers follow.

**Figure 12-64. FTM counter synchronization with (SYNCMODE = 0), (REINIT = 1), (PWMSYNC = 0), and software trigger was used**

**Figure 12-65. FTM counter synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (REINIT = 1), (PWMSYNC = 0), and a hardware trigger was used**

If (SYNCMODE = 0), (REINIT = 1), and (PWMSYNC = 1) then this synchronization is made on the next enabled hardware trigger. The TRIGn bit is cleared according to [Hardware trigger](#).

**Figure 12-66. FTM counter synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (REINIT = 1), (PWMSYNC = 1), and a hardware trigger was used**

## 12.2.4.12 Inverting

The invert functionality swaps the signals between channel (n) and channel (n+1) outputs. The inverting operation is selected when:

- QUADEN = 0
- DECAPEN = 0
- COMP = 1, and
- INV<sub>m</sub> = 1 (where m represents a channel pair)

The INV<sub>m</sub> bit in INVCTRL register is updated with its buffer value according to [INVCTRL register synchronization](#)

In High-True (ELSnB:ELSnA = 1:0) Combine mode, the channel (n) output is forced low at the beginning of the period (FTM counter = CNTIN), forced high at the channel (n) match and forced low at the channel (n+1) match. If the inverting is selected, the channel (n) output behavior is changed to force high at the beginning of the PWM period, force low at the channel (n) match and force high at the channel (n+1) match. See the following figure.

## NOTE

INV<sub>m</sub> bit selects the inverting to the pair channels (n) and (n+1).

**Figure 12-67. Channels (n) and (n+1) outputs after the inverting in High-True (ELSnB:ELSnA = 1:0) Combine mode**

Note that the ELSnB:ELSnA bits value should be considered because they define the active state of the channels outputs. In Low-True (ELSnB:ELSnA = X:1) Combine mode, the channel (n) output is forced high at the beginning of the period, forced low at the channel (n) match and forced high at the channel (n+1) match. When inverting is selected, the channels (n) and (n+1) present waveforms as shown in the following figure.

NOTE  
INV(m) bit selects the inverting to the pair channels (n) and (n+1).

**Figure 12-68. Channels (n) and (n+1) outputs after the inverting in Low-True (ELSnB:ELSnA = X:1) Combine mode**

### Note

The inverting feature is not available in Output Compare mode.

#### 12.2.4.13 Software output control

The software output control forces the channel output according to software defined values at a specific time in the PWM generation.

The software output control is selected when:

- QUADEN = 0
- DECAPEN = 0, and
- CHnOC = 1

## Flextimer (FTM)

The CHnOC bit enables the software output control for a specific channel output and the CHnOCV selects the value that is forced to this channel output.

Both CHnOC and CHnOCV bits in SWOCTRL register are buffered and updated with their buffer value according to [SWOCTRL register synchronization](#).

The following figure shows the channels (n) and (n+1) outputs signals when the software output control is used. In this case the channels (n) and (n+1) are set to Combine and Complementary mode.

NOTE  
CH(n)OCV = 1 and CH(n+1)OCV = 0.

**Figure 12-69. Example of software output control in Combine and Complementary mode**

Software output control forces the following values on channels (n) and (n+1) when the COMP bit is zero.

**Table 12-10. Software output control behavior when (COMP = 0)**

CH(n)OC	CH(n+1)OC	CH(n)OCV	CH(n+1)OCV	Channel (n) Output	Channel (n+1) Output
0	0	X	X	is not modified by SWOC	is not modified by SWOC
1	1	0	0	is forced to zero	is forced to zero
1	1	0	1	is forced to zero	is forced to one
1	1	1	0	is forced to one	is forced to zero
1	1	1	1	is forced to one	is forced to one

Software output control forces the following values on channels (n) and (n+1) when the COMP bit is one.

**Table 12-11. Software output control behavior when (COMP = 1)**

CH(n)OC	CH(n+1)OC	CH(n)OCV	CH(n+1)OCV	Channel (n) Output	Channel (n+1) Output
0	0	X	X	is not modified by SWOC	is not modified by SWOC
1	1	0	0	is forced to zero	is forced to zero
1	1	0	1	is forced to zero	is forced to one
1	1	1	0	is forced to one	is forced to zero
1	1	1	1	is forced to one	is forced to zero

**Note**

- The CH(n)OC and CH(n+1)OC bits should be equal.
- The COMP bit must not be modified when software output control is enabled, that is, CH(n)OC = 1 and/or CH(n+1)OC = 1.
- Software output control has the same behavior with disabled or enabled FTM counter (see the CLKS field description in the Status and Control register).

**12.2.4.14 Deadtime insertion**

The deadtime insertion is enabled when (DTEN = 1) and (DTVVAL[5:0] is non-zero).

DEADTIME register defines the deadtime delay that can be used for all FTM channels. The DTTPS[1:0] bits define the prescaler for the system clock and the DTVVAL[5:0] bits define the deadtime modulo, that is, the number of the deadtime prescaler clocks.

The deadtime delay insertion ensures that no two complementary signals (channels (n) and (n+1)) drive the active state at the same time.

If POL(n) = 0, POL(n+1) = 0, and the deadtime is enabled, then when the channel (n) match (FTM counter = C(n)V) occurs, the channel (n) output remains at the low value until the end of the deadtime delay when the channel (n) output is set. Similarly, when the channel (n+1) match (FTM counter = C(n+1)V) occurs, the channel (n+1) output remains at the low value until the end of the deadtime delay when the channel (n+1) output is set. See the following figures.

If POL(n) = 1, POL(n+1) = 1, and the deadtime is enabled, then when the channel (n) match (FTM counter = C(n)V) occurs, the channel (n) output remains at the high value until the end of the deadtime delay when the channel (n) output is cleared. Similarly,

## Flextimer (FTM)

when the channel (n+1) match (FTM counter =  $C(n+1)V$ ) occurs, the channel (n+1) output remains at the high value until the end of the deadtime delay when the channel (n+1) output is cleared.

**Figure 12-70. Deadtime insertion with  $ELSnB:ELSnA = 1:0$ ,  $POL(n) = 0$ , and  $POL(n+1) = 0$**

**Figure 12-71. Deadtime insertion with  $ELSnB:ELSnA = X:1$ ,  $POL(n) = 0$ , and  $POL(n+1) = 0$**

### NOTE

- The deadtime feature must be used only in Complementary mode.
- The deadtime feature is not available in Output Compare mode.

#### 12.2.4.14.1 Deadtime insertion corner cases

If (PS[2:0] is cleared), (DTPS[1:0] = 0:0 or DTPS[1:0] = 0:1):

- and the deadtime delay is greater than or equal to the channel (n) duty cycle ( $(C(n+1)V - C(n)V) \times \text{system clock}$ ), then the channel (n) output is always the inactive value (POL(n) bit value).
- and the deadtime delay is greater than or equal to the channel (n+1) duty cycle ( $(\text{MOD} - \text{CNTIN} + 1 - (C(n+1)V - C(n)V)) \times \text{system clock}$ ), then the channel (n+1) output is always the inactive value (POL(n+1) bit value).

Although, in most cases the deadtime delay is not comparable to channels (n) and (n+1) duty cycle, the following figures show examples where the deadtime delay is comparable to the duty cycle.

**Figure 12-72. Example of the deadtime insertion (ELSnB:ELSnA = 1:0, POL(n) = 0, and POL(n+1) = 0) when the deadtime delay is comparable to channel (n+1) duty cycle**

**Figure 12-73. Example of the deadtime insertion (ELSnB:ELSnA = 1:0, POL(n) = 0, and POL(n+1) = 0) when the deadtime delay is comparable to channels (n) and (n+1) duty cycle**

### 12.2.4.15 Output mask

The output mask can be used to force channels output to their inactive state through software. For example: to control a BLDC motor.

Any write to the OUTMASK register updates its write buffer. The OUTMASK register is updated with its buffer value by PWM synchronization; see [OUTMASK register synchronization](#).

If CHnOM = 1, then the channel (n) output is forced to its inactive state (POLn bit value). If CHnOM = 0, then the channel (n) output is unaffected by the output mask. See the following figure.

**Figure 12-74. Output mask with POLn = 0**

The following table shows the output mask result before the polarity control.

**Table 12-12. Output mask result for channel (n) before the polarity control**

CHnOM	Output Mask Input	Output Mask Result
0	inactive state	inactive state
	active state	active state
1	inactive state	inactive state
	active state	inactive state

### 12.2.4.16 Polarity control

The POLn bit selects the channel (n) output polarity:

- If POLn = 0, the channel (n) output polarity is high, so the logical one is the active state and the logical zero is the inactive state.
- If POLn = 1, the channel (n) output polarity is low, so the logical zero is the active state and the logical one is the inactive state.

### 12.2.4.17 Initialization

The initialization forces the CHnOI bit value to the channel (n) output when a one is written to the INIT bit.

The initialization depends on COMP and DTEN bits. The following table shows the values that channels (n) and (n+1) are forced by initialization when the COMP and DTEN bits are zero.

**Table 12-13. Initialization behavior when (COMP = 0 and DTEN = 0)**

CH(n)OI	CH(n+1)OI	Channel (n) Output	Channel (n+1) Output
0	0	is forced to zero	is forced to zero
0	1	is forced to zero	is forced to one
1	0	is forced to one	is forced to zero
1	1	is forced to one	is forced to one

The following table shows the values that channels (n) and (n+1) are forced by initialization when (COMP = 1) or (DTEN = 1).

**Table 12-14. Initialization behavior when (COMP = 1 or DTEN = 1)**

CH(n)OI	CH(n+1)OI	Channel (n) Output	Channel (n+1) Output
0	X	is forced to zero	is forced to one
1	X	is forced to one	is forced to zero

#### Note

The initialization feature must be used only with disabled FTM counter. See the description of the CLKS field in the Status and Control register.

### 12.2.4.18 Features priority

The following figure shows the priority of the features used at the generation of channels (n) and (n+1) outputs signals.

NOTE  
The channels (n) and (n+1) are in output compare, EPWM, CPWM or combine modes.

**Figure 12-75. Priority of the features used at the generation of channels (n) and (n+1) outputs signals**

#### Note

The **Initialization** feature must not be used with **Inverting** and **Software output control** features.

### 12.2.4.19 Channel trigger output

If CH(j)TRIG bit of the FTM External Trigger (FTM\_EXTTRIG) register is set, where  $j = 0, 1, 2, 3, 4,$  or  $5$ , then the FTM generates a trigger when the channel (j) match occurs (FTM counter = C(j)V).

The channel trigger output provides a trigger signal which has one FTM clock period width and is used for on-chip modules.

The FTM is able to generate multiple triggers in one PWM period. Because each trigger is generated for a specific channel, several channels are required to implement this functionality. This behavior is described in the following figure.

**Figure 12-76. Channel match trigger**

### 12.2.4.20 Initialization trigger

If INITTRIGEN = 1, then the FTM generates a trigger when the FTM counter is updated with the CNTIN register value in the following cases.

- The FTM counter is automatically updated with the CNTIN register value by the selected counting mode.
- When there is a write to CNT register.
- When there is the [FTM counter synchronization](#).
- If (CNT = CNTIN), (CLKS[1:0] = 0:0), and a value different from zero is written to CLKS[1:0] bits.
- If the channel (n) is in Input Capture mode, (ICRST = 1) and the selected input capture event occurs in the channel (n) input.

The following figures show these cases.

**Figure 12-77. Initialization trigger is generated when the FTM counting achieves the CNTIN register value**

**Figure 12-78. Initialization trigger is generated when there is a write to CNT register**

CNTIN = 0x0000  
 MOD = 0x000F  
 CPWMS = 0

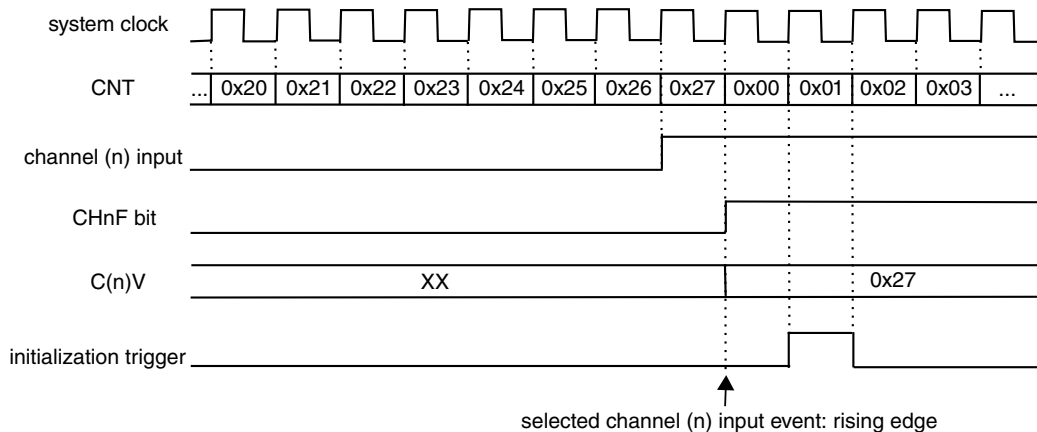

**Figure 12-79. Initialization trigger is generated when there is the FTM counter synchronization**

CNTIN = 0x0000  
 MOD = 0x000F  
 CPWMS = 0

**Figure 12-80. Initialization trigger is generated if (CNT = CNTIN), (CLKS[1:0] = 0:0), and a value different from zero is written to CLKS[1:0] bits**

NOTE  
 Channel (n) input after its synchronizer and filter  
 MOD = 0xFFFF  
 CNTIN = 0x0000  
 PS[2:0] = 3'b000  
 ICRST = 1'b1

**Figure 12-81. Initialization trigger is generated if the channel (n) is in Input Capture mode, ICRST = 1 and the selected input capture event occurs in the channel (n) input**

The initialization trigger output provides a trigger signal that is used for on-chip modules.

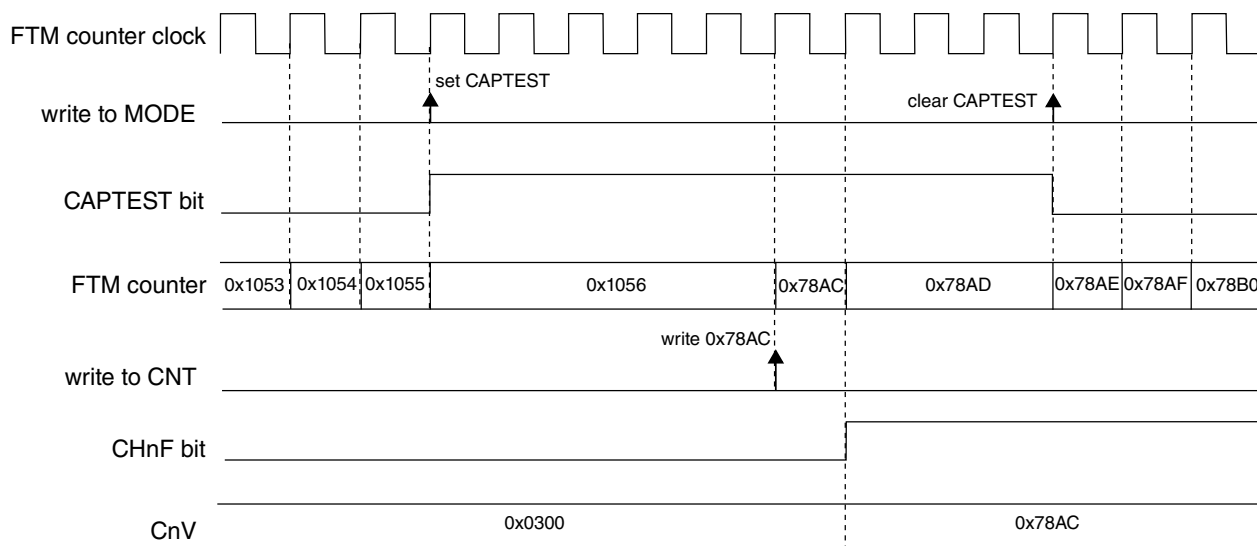

### 12.2.4.21 Capture Test mode

The Capture Test mode allows to test the CnV registers, the FTM counter and the interconnection logic between the FTM counter and CnV registers.

In this test mode, all channels must be configured for **Input Capture mode** and FTM counter must be configured to the **Up counting**.

When the Capture Test mode is enabled (CAPTEST = 1), the FTM counter is frozen and any write to CNT register updates directly the FTM counter; see the following figure. After it was written, all CnV registers are updated with the written value to CNT register and CHnF bits are set. Therefore, the FTM counter is updated with its next value according to its configuration. Its next value depends on CNTIN, MOD, and the written value to FTM counter.

The next reads of CnV registers return the written value to the FTM counter and the next reads of CNT register return FTM counter next value.

**NOTE**

- FTM counter configuration: (FTMEN = 1), (QUADEN = 0), (CAPTEST = 1), (CPWMS = 0), (CNTIN = 0x0000), and (MOD = 0xFFFF)
- FTM channel n configuration: input capture mode - (DECAPEN = 0), (COMBINE = 0), and (MSnB:MSnA = 0:0)

**Figure 12-82. Capture Test mode**

### 12.2.4.22 DMA

The channel generates a DMA transfer request according to DMA and CHnIE bits. See the following table.

**Table 12-15. Channel DMA transfer request**

DMA	CHnIE	Channel DMA Transfer Request	Channel Interrupt
0	0	The channel DMA transfer request is not generated.	The channel interrupt is not generated.
0	1	The channel DMA transfer request is not generated.	The channel interrupt is generated if (CHnF = 1).
1	0	The channel DMA transfer request is not generated.	The channel interrupt is not generated.
1	1	The channel DMA transfer request is generated if (CHnF = 1).	The channel interrupt is not generated.

If DMA = 1, the CHnF bit is cleared either by channel DMA transfer done or reading CnSC while CHnF is set and then writing a zero to CHnF bit according to CHnIE bit. See the following table.

**Table 12-16. Clear CHnF bit when DMA = 1**

CHnIE	How CHnF Bit Can Be Cleared
0	CHnF bit is cleared either when the channel DMA transfer is done or by reading CnSC while CHnF is set and then writing a 0 to CHnF bit.
1	CHnF bit is cleared when the channel DMA transfer is done.

### 12.2.4.23 Dual Edge Capture mode

The Dual Edge Capture mode is selected if DECAPEN = 1. This mode allows to measure a pulse width or period of the signal on the input of channel (n) of a channel pair. The channel (n) filter can be active in this mode when n is 0 or 2.

**Figure 12-83. Dual Edge Capture mode block diagram**

The MS(n)A bit defines if the Dual Edge Capture mode is one-shot or continuous.

The ELS(n)B:ELS(n)A bits select the edge that is captured by channel (n), and ELS(n+1)B:ELS(n+1)A bits select the edge that is captured by channel (n+1). If both ELS(n)B:ELS(n)A and ELS(n+1)B:ELS(n+1)A bits select the same edge, then it is the period measurement. If these bits select different edges, then it is a pulse width measurement.

In the Dual Edge Capture mode, only channel (n) input is used and channel (n+1) input is ignored.

If the selected edge by channel (n) bits is detected at channel (n) input, then CH(n)F bit is set and the channel (n) interrupt is generated (if CH(n)IE = 1). If the selected edge by channel (n+1) bits is detected at channel (n) input and (CH(n)F = 1), then CH(n+1)F bit is set and the channel (n+1) interrupt is generated (if CH(n+1)IE = 1).

The C(n)V register stores the value of FTM counter when the selected edge by channel (n) is detected at channel (n) input. The C(n+1)V register stores the value of FTM counter when the selected edge by channel (n+1) is detected at channel (n) input.

In this mode, a coherency mechanism ensures coherent data when the C(n)V and C(n+1)V registers are read. The only requirement is that C(n)V must be read before C(n+1)V.

### Note

- The CH(n)F, CH(n)IE, MS(n)A, ELS(n)B, and ELS(n)A bits are channel (n) bits.

- The CH(n+1)F, CH(n+1)IE, MS(n+1)A, ELS(n+1)B, and ELS(n+1)A bits are channel (n+1) bits.
- The Dual Edge Capture mode must be used with ELS(n)B:ELS(n)A = 0:1 or 1:0, ELS(n+1)B:ELS(n+1)A = 0:1 or 1:0 and the FTM counter in [Free running counter](#).

#### 12.2.4.23.1 One-Shot Capture mode

The One-Shot Capture mode is selected when (DECAPEN = 1), and (MS(n)A = 0). In this capture mode, only one pair of edges at the channel (n) input is captured. The ELS(n)B:ELS(n)A bits select the first edge to be captured, and ELS(n+1)B:ELS(n+1)A bits select the second edge to be captured.

The edge captures are enabled while DECAP bit is set. For each new measurement in One-Shot Capture mode, first the CH(n)F and CH(n+1) bits must be cleared, and then the DECAP bit must be set.

In this mode, the DECAP bit is automatically cleared by FTM when the edge selected by channel (n+1) is captured. Therefore, while DECAP bit is set, the one-shot capture is in process. When this bit is cleared, both edges were captured and the captured values are ready for reading in the C(n)V and C(n+1)V registers.

Similarly, when the CH(n+1)F bit is set, both edges were captured and the captured values are ready for reading in the C(n)V and C(n+1)V registers.

#### 12.2.4.23.2 Continuous Capture mode

The Continuous Capture mode is selected when (DECAPEN = 1), and (MS(n)A = 1). In this capture mode, the edges at the channel (n) input are captured continuously. The ELS(n)B:ELS(n)A bits select the initial edge to be captured, and ELS(n+1)B:ELS(n+1)A bits select the final edge to be captured.

The edge captures are enabled while DECAP bit is set. For the initial use, first the CH(n)F and CH(n+1)F bits must be cleared, and then DECAP bit must be set to start the continuous measurements.

When the CH(n+1)F bit is set, both edges were captured and the captured values are ready for reading in the C(n)V and C(n+1)V registers. The latest captured values are always available in these registers even after the DECAP bit is cleared.

In this mode, it is possible to clear only the CH(n+1)F bit. Therefore, when the CH(n+1)F bit is set again, the latest captured values are available in C(n)V and C(n+1)V registers.

For a new sequence of the measurements in the Dual Edge Capture – Continuous mode, clear the CH(n)F and CH(n+1)F bits to start new measurements.

### 12.2.4.23.3 Pulse width measurement

If the channel (n) is configured to capture rising edges (ELS(n)B:ELS(n)A = 0:1) and the channel (n+1) to capture falling edges (ELS(n+1)B:ELS(n+1)A = 1:0), then the positive polarity pulse width is measured. If the channel (n) is configured to capture falling edges (ELS(n)B:ELS(n)A = 1:0) and the channel (n+1) to capture rising edges (ELS(n+1)B:ELS(n+1)A = 0:1), then the negative polarity pulse width is measured.

The pulse width measurement can be made in [One-Shot Capture mode](#) or [Continuous Capture mode](#).

The following figure shows an example of the Dual Edge Capture – One-Shot mode used to measure the positive polarity pulse width. The DECAPEN bit selects the Dual Edge Capture mode, so it remains set. The DECAP bit is set to enable the measurement of next positive polarity pulse width. The CH(n)F bit is set when the first edge of this pulse is detected, that is, the edge selected by ELS(n)B:ELS(n)A bits. The CH(n+1)F bit is set and DECAP bit is cleared when the second edge of this pulse is detected, that is, the edge selected by ELS(n+1)B:ELS(n+1)A bits. Both DECAP and CH(n+1)F bits indicate when two edges of the pulse were captured and the C(n)V and C(n+1)V registers are ready for reading.

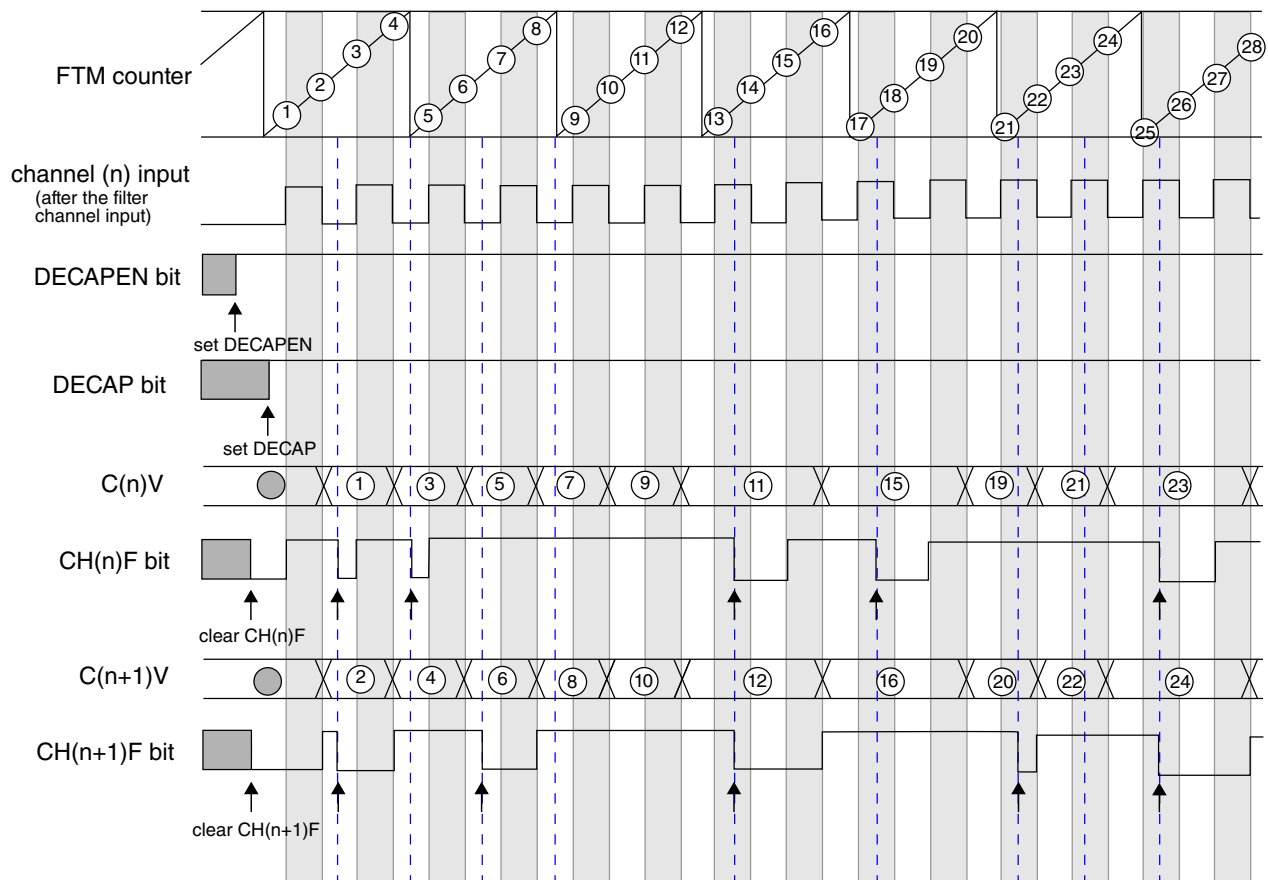

## Note

- The commands set DECAPEN, set DECAP, clear CH(n)F, and clear CH(n+1)F are made by the user.
- Problem 1: channel (n) input = 1, set DECAP, not clear CH(n)F, and clear CH(n+1)F.
- Problem 2: channel (n) input = 1, set DECAP, not clear CH(n)F, and not clear CH(n+1)F.

**Figure 12-84. Dual Edge Capture – One-Shot mode for positive polarity pulse width measurement**

The following figure shows an example of the Dual Edge Capture – Continuous mode used to measure the positive polarity pulse width. The DECAPEN bit selects the Dual Edge Capture mode, so it remains set. While the DECAP bit is set the configured measurements are made. The CH(n)F bit is set when the first edge of the positive polarity pulse is detected, that is, the edge selected by ELS(n)B:ELS(n)A bits. The CH(n+1)F bit is set when the second edge of this pulse is detected, that is, the edge selected by ELS(n+1)B:ELS(n+1)A bits. The CH(n+1)F bit indicates when two edges of the pulse were captured and the C(n)V and C(n+1)V registers are ready for reading.

Note  
 - The commands set DECAPEN, set DECAP, clear CH(n)F, and clear CH(n+1)F are made by the user.

**Figure 12-85. Dual Edge Capture – Continuous mode for positive polarity pulse width measurement**

### 12.2.4.23.4 Period measurement

If the channels (n) and (n+1) are configured to capture consecutive edges of the same polarity, then the period of the channel (n) input signal is measured. If both channels (n) and (n+1) are configured to capture rising edges ( $ELS(n)B:ELS(n)A = 0:1$  and  $ELS(n+1)B:ELS(n+1)A = 0:1$ ), then the period between two consecutive rising edges is measured. If both channels (n) and (n+1) are configured to capture falling edges ( $ELS(n)B:ELS(n)A = 1:0$  and  $ELS(n+1)B:ELS(n+1)A = 1:0$ ), then the period between two consecutive falling edges is measured.

The period measurement can be made in [One-Shot Capture mode](#) or [Continuous Capture mode](#).

The following figure shows an example of the Dual Edge Capture – One-Shot mode used to measure the period between two consecutive rising edges. The DECAPEN bit selects the Dual Edge Capture mode, so it remains set. The DECAP bit is set to enable the

measurement of next period. The CH(n)F bit is set when the first rising edge is detected, that is, the edge selected by ELS(n)B:ELS(n)A bits. The CH(n+1)F bit is set and DECAP bit is cleared when the second rising edge is detected, that is, the edge selected by ELS(n+1)B:ELS(n+1)A bits. Both DECAP and CH(n+1)F bits indicate when two selected edges were captured and the C(n)V and C(n+1)V registers are ready for reading.

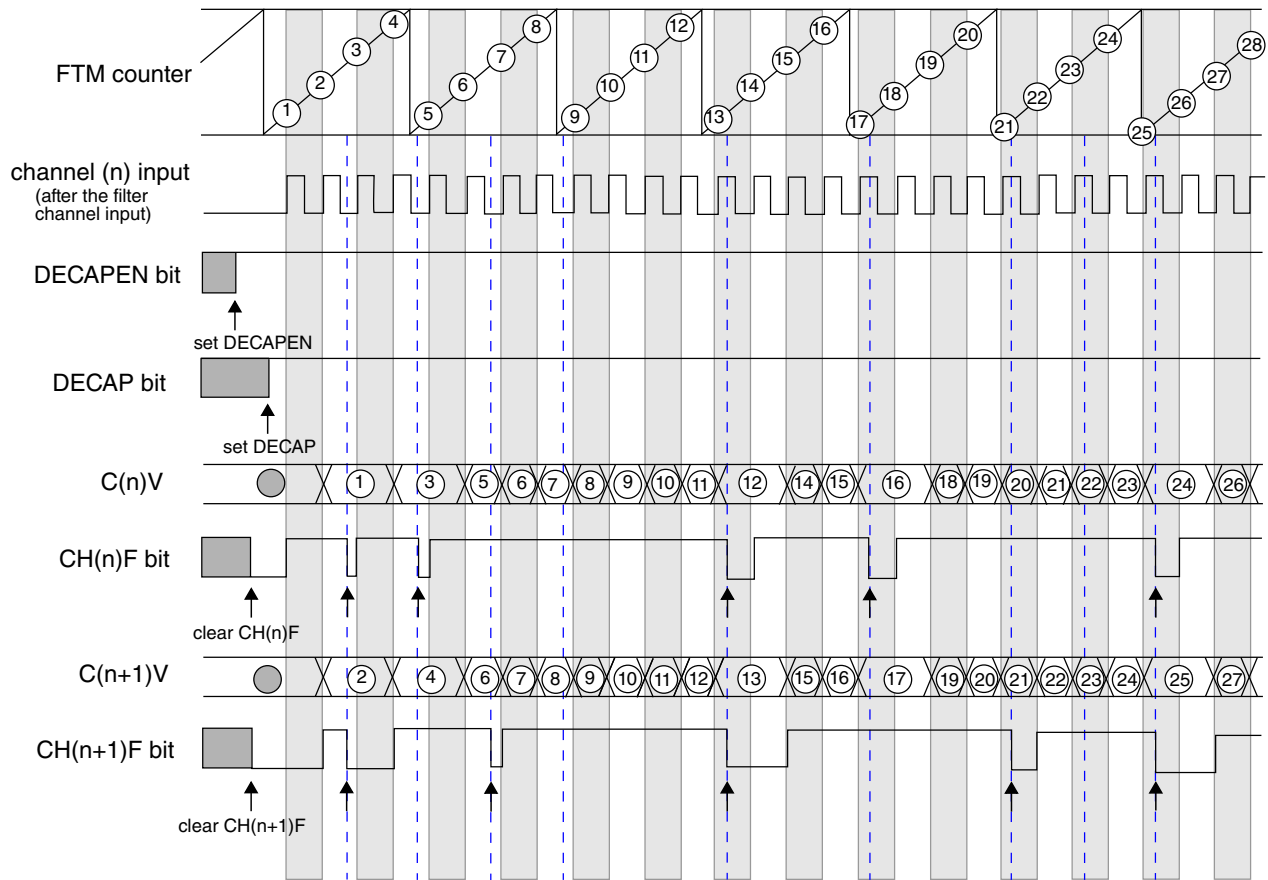

Note

- The commands set DECAPEN, set DECAP, clear CH(n)F, and clear CH(n+1)F are made by the user.
- Problem 1: channel (n) input = 0, set DECAP, not clear CH(n)F, and not clear CH(n+1)F.
- Problem 2: channel (n) input = 1, set DECAP, not clear CH(n)F, and clear CH(n+1)F.
- Problem 3: channel (n) input = 1, set DECAP, not clear CH(n)F, and not clear CH(n+1)F.

**Figure 12-86. Dual Edge Capture – One-Shot mode to measure of the period between two consecutive rising edges**

The following figure shows an example of the Dual Edge Capture – Continuous mode used to measure the period between two consecutive rising edges. The DECAPEN bit selects the Dual Edge Capture mode, so it remains set. While the DECAP bit is set the configured measurements are made. The CH(n)F bit is set when the first rising edge is detected, that is, the edge selected by ELS(n)B:ELS(n)A bits. The CH(n+1)F bit is set when the second rising edge is detected, that is, the edge selected by ELS(n+1)B:ELS(n+1)A bits. The CH(n+1)F bit indicates when two edges of the period were captured and the C(n)V and C(n+1)V registers are ready for reading.

Note  
 - The commands set DECAPEN, set DECAP, clear CH(n)F, and clear CH(n+1)F are made by the user.

**Figure 12-87. Dual Edge Capture – Continuous mode to measure of the period between two consecutive rising edges**

### 12.2.4.23.5 Read coherency mechanism

The Dual Edge Capture mode implements a read coherency mechanism between the FTM counter value captured in C(n)V and C(n+1)V registers. The read coherency mechanism is illustrated in the following figure. In this example, the channels (n) and (n+1) are in Dual Edge Capture – Continuous mode for positive polarity pulse width measurement. Thus, the channel (n) is configured to capture the FTM counter value when there is a rising edge at channel (n) input signal, and channel (n+1) to capture the FTM counter value when there is a falling edge at channel (n) input signal.

When a rising edge occurs in the channel (n) input signal, the FTM counter value is captured into channel (n) capture buffer. The channel (n) capture buffer value is transferred to C(n)V register when a falling edge occurs in the channel (n) input signal.

$C(n)V$  register has the FTM counter value when the previous rising edge occurred, and the channel (n) capture buffer has the FTM counter value when the last rising edge occurred.

When a falling edge occurs in the channel (n) input signal, the FTM counter value is captured into channel (n+1) capture buffer. The channel (n+1) capture buffer value is transferred to  $C(n+1)V$  register when the  $C(n)V$  register is read.

In the following figure, the read of  $C(n)V$  returns the FTM counter value when the event 1 occurred and the read of  $C(n+1)V$  returns the FTM counter value when the event 2 occurred.

**Figure 12-88. Dual Edge Capture mode read coherency mechanism**

$C(n)V$  register must be read prior to  $C(n+1)V$  register in dual edge capture one-shot and continuous modes for the read coherency mechanism works properly.

#### 12.2.4.24 Quadrature Decoder mode

The Quadrature Decoder mode is selected if ( $QUADEN = 1$ ). The Quadrature Decoder mode uses the input signals phase A and B to control the FTM counter increment and decrement. The following figure shows the quadrature decoder block diagram.

**Figure 12-89. Quadrature Decoder block diagram**

Each one of input signals phase A and B has a filter that is equivalent to the filter used in the channels input; [Filter for Input Capture mode](#). The phase A input filter is enabled by PHAFLTREN bit and this filter's value is defined by CH0FVAL[3:0] bits (CH(n)FVAL[3:0] bits in FILTER0 register). The phase B input filter is enabled by PHBFLTREN bit and this filter's value is defined by CH1FVAL[3:0] bits (CH(n+1)FVAL[3:0] bits in FILTER0 register).

Except for CH0FVAL[3:0] and CH1FVAL[3:0] bits, no channel logic is used in Quadrature Decoder mode.

### Note

Notice that the FTM counter is clocked by the phase A and B input signals when quadrature decoder mode is selected. Therefore it is expected that the Quadrature Decoder be used only with the FTM channels in input capture or output compare modes.

### Note

An edge at phase A must not occur together an edge at phase B and vice-versa.

The PHAPOL bit selects the polarity of the phase A input, and the PHBPOL bit selects the polarity of the phase B input.

The QUADM0DE selects the encoding mode used in the Quadrature Decoder mode. If QUADM0DE = 1, then the count and direction encoding mode is enabled; see the following figure. In this mode, the phase B input value indicates the counting direction, and the phase A input defines the counting rate. The FTM counter is updated when there is a rising edge at phase A input signal.

**Figure 12-90. Quadrature Decoder – Count and Direction Encoding mode**

If QUADM0DE = 0, then the Phase A and Phase B Encoding mode is enabled; see the following figure. In this mode, the relationship between phase A and B signals indicates the counting direction, and phase A and B signals define the counting rate. The FTM counter is updated when there is an edge either at the phase A or phase B signals.

If PHAPOL = 0 and PHBPOL = 0, then the FTM counter increment happens when:

- there is a rising edge at phase A signal and phase B signal is at logic zero;
- there is a rising edge at phase B signal and phase A signal is at logic one;
- there is a falling edge at phase B signal and phase A signal is at logic zero;
- there is a falling edge at phase A signal and phase B signal is at logic one;

and the FTM counter decrement happens when:

- there is a falling edge at phase A signal and phase B signal is at logic zero;
- there is a falling edge at phase B signal and phase A signal is at logic one;
- there is a rising edge at phase B signal and phase A signal is at logic zero;
- there is a rising edge at phase A signal and phase B signal is at logic one.

## Flextimer (FTM)

**Figure 12-91. Quadrature Decoder – Phase A and Phase B Encoding mode**

The following figure shows the FTM counter overflow in up counting. In this case, when the FTM counter changes from MOD to CNTIN, TOF and TOFDIR bits are set. TOF bit indicates the FTM counter overflow occurred. TOFDIR indicates the counting was up when the FTM counter overflow occurred.

**Figure 12-92. FTM Counter overflow in up counting for Quadrature Decoder mode**

The following figure shows the FTM counter overflow in down counting. In this case, when the FTM counter changes from CNTIN to MOD, TOF bit is set and TOFDIR bit is cleared. TOF bit indicates the FTM counter overflow occurred. TOFDIR indicates the counting was down when the FTM counter overflow occurred.

Figure 12-93. FTM counter overflow in down counting for Quadrature Decoder mode

### 12.2.4.24.1 Quadrature Decoder boundary conditions

The following figures show the FTM counter responding to motor jittering typical in motor position control applications.

Figure 12-94. Motor position jittering in a mid count value

The following figure shows motor jittering produced by the phase B and A pulses respectively:

## Flextimer (FTM)

**Figure 12-95. Motor position jittering near maximum and minimum count value**

The first highlighted transition causes a jitter on the FTM counter value near the maximum count value (MOD). The second indicated transition occurs on phase A and causes the FTM counter transition between the maximum and minimum count values which are defined by MOD and CNTIN registers.

The appropriate settings of the phase A and phase B input filters are important to avoid glitches that may cause oscillation on the FTM counter value. The preceding figures show examples of oscillations that can be caused by poor input filter setup. Thus, it is important to guarantee a minimum pulse width to avoid these oscillations.

### 12.2.4.25 Intermediate load

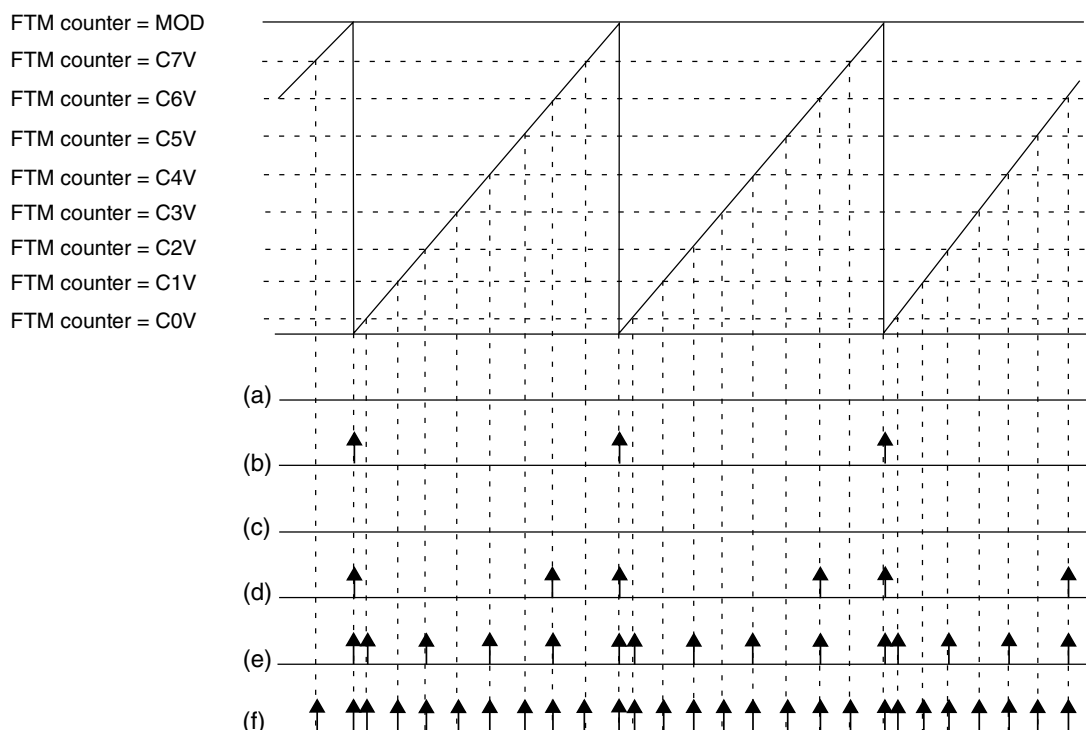

The PWMLOAD register allows to update the MOD, CNTIN, and C(n)V registers with the content of the register buffer at a defined load point. In this case, it is not required to use the PWM synchronization.

There are multiple possible loading points for intermediate load:

**Table 12-17. When possible loading points are enabled**

Loading point	Enabled
When the FTM counter wraps from MOD value to CNTIN value	Always
At the channel (j) match (FTM counter = C(j)V)	When CHjSEL = 1

The following figure shows some examples of enabled loading points.

**NOTE**

- (a) LDOK = 0, CH0SEL = 0, CH1SEL = 0, CH2SEL = 0, CH3SEL = 0, CH4SEL = 0, CH5SEL = 0, CH6SEL = 0, CH7SEL = 0  
 (b) LDOK = 1, CH0SEL = 0, CH1SEL = 0, CH2SEL = 0, CH3SEL = 0, CH4SEL = 0, CH5SEL = 0, CH6SEL = 0, CH7SEL = 0  
 (c) LDOK = 0, CH0SEL = 0, CH1SEL = 0, CH2SEL = 0, CH3SEL = 1, CH4SEL = 0, CH5SEL = 0, CH6SEL = 0, CH7SEL = 0  
 (d) LDOK = 1, CH0SEL = 0, CH1SEL = 0, CH2SEL = 0, CH3SEL = 0, CH4SEL = 0, CH5SEL = 0, CH6SEL = 1, CH7SEL = 0  
 (e) LDOK = 1, CH0SEL = 1, CH1SEL = 0, CH2SEL = 1, CH3SEL = 0, CH4SEL = 1, CH5SEL = 0, CH6SEL = 1, CH7SEL = 0  
 (f) LDOK = 1, CH0SEL = 1, CH1SEL = 1, CH2SEL = 1, CH3SEL = 1, CH4SEL = 1, CH5SEL = 1, CH6SEL = 1, CH7SEL = 1

**Figure 12-96. Loading points for intermediate load**

After enabling the loading points, the LDOK bit must be set for the load to occur. In this case, the load occurs at the next enabled loading point according to the following conditions:

**Table 12-18. Conditions for loads occurring at the next enabled loading point**

When a new value was written	Then
To the MOD register	The MOD register is updated with its write buffer value.
To the CNTIN register and CNTINC = 1	The CNTIN register is updated with its write buffer value.
To the C(n)V register and SYNCEN <sub>m</sub> = 1 – where m indicates the pair channels (n) and (n+1)	The C(n)V register is updated with its write buffer value.
To the C(n+1)V register and SYNCEN <sub>m</sub> = 1 – where m indicates the pair channels (n) and (n+1)	The C(n+1)V register is updated with its write buffer value.

**NOTE**

- If ELS<sub>j</sub>B and ELS<sub>j</sub>A bits are different from zero, then the channel (j) output signal is generated according to the configured output mode. If ELS<sub>j</sub>B and ELS<sub>j</sub>A bits are zero,

then the generated signal is not available on channel (j) output.

- If  $CHjIE = 1$ , then the channel (j) interrupt is generated when the channel (j) match occurs.
- At the intermediate load neither the channels outputs nor the FTM counter are changed. Software must set the intermediate load at a safe point in time.

### 12.2.4.26 Global time base (GTB)

The global time base (GTB) is a FTM function that allows the synchronization of multiple FTM modules on a chip. The following figure shows an example of the GTB feature used to synchronize two FTM modules. In this case, the FTM A and B channels can behave as if just one FTM module was used, that is, a global time base.

**Figure 12-97. Global time base (GTB) block diagram**

The GTB functionality is implemented by the GTBEEN and GTBEOUT bits in the CONF register, the input signal *gtb\_in*, and the output signal *gtb\_out*. The GTBEEN bit enables *gtb\_in* to control the FTM counter enable signal:

- If  $GTBEEN = 0$ , each one of FTM modules works independently according to their configured mode.
- If  $GTBEEN = 1$ , the FTM counter update is enabled only when *gtb\_in* is 1.

In the configuration described in the preceding figure, FTM modules A and B have their FTM counters enabled if at least one of the *gtb\_out* signals from one of the FTM modules is 1. There are several possible configurations for the interconnection of the *gtb\_in* and *gtb\_out* signals, represented by the example glue logic shown in the figure. Note that these configurations are chip-dependent and implemented outside of the FTM modules. See the chip-specific FTM information for the chip's specific implementation.

**NOTE**

- In order to use the GTB signals to synchronize the FTM counter of different FTM modules, the configuration of each FTM module should guarantee that its FTM counter starts counting as soon as the `gtb_in` signal is 1.
- The GTB feature does not provide continuous synchronization of FTM counters, meaning that the FTM counters may lose synchronization during FTM operation. The GTB feature only allows the FTM counters to *start* their operation synchronously.

**12.2.4.26.1 Enabling the global time base (GTB)**

To enable the GTB feature, follow these steps for each participating FTM module:

1. Stop the FTM counter: Write 00b to SC[CLKS].
2. Program the FTM to the intended configuration. The FTM counter mode needs to be consistent across all participating modules.
3. Write 1 to CONF[GTBEEN] and write 0 to CONF[GTBEOUT] at the same time.
4. Select the intended FTM counter clock source in SC[CLKS]. The clock source needs to be consistent across all participating modules.
5. Reset the FTM counter: Write any value to the CNT register.

To initiate the GTB feature in the configuration described in the preceding figure, write 1 to CONF[GTBEOUT] in the FTM module used as the time base.

**12.2.5 Reset overview**

The FTM is reset whenever any chip reset occurs.

When the FTM exits from reset:

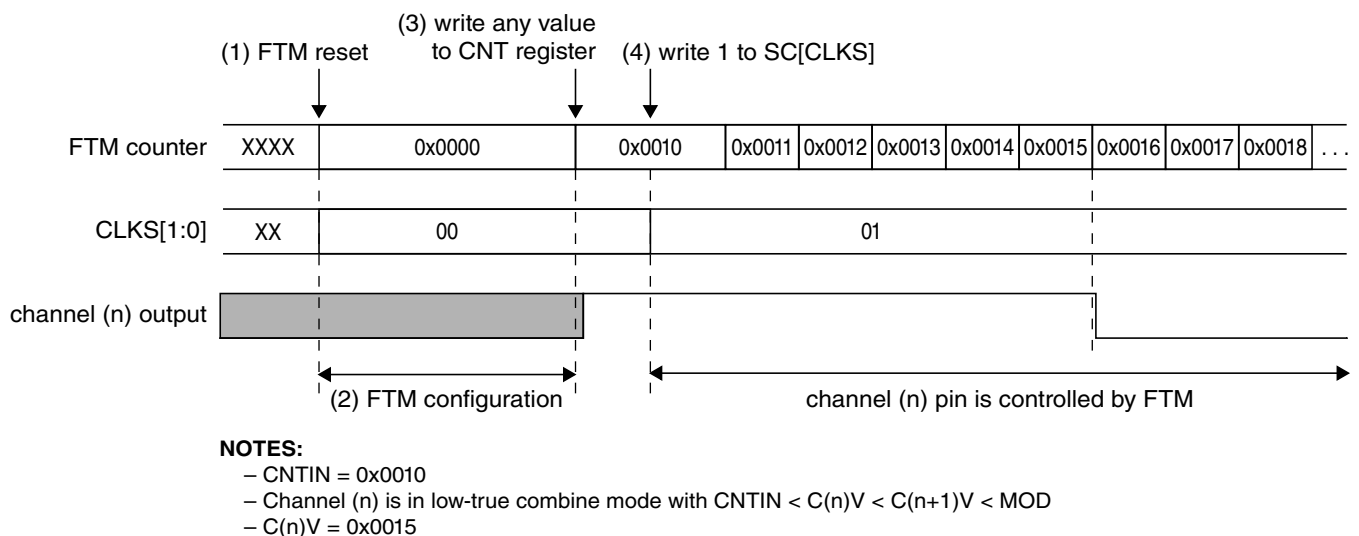

- the FTM counter and the prescaler counter are zero and are stopped (CLKS[1:0] = 00b);
- the timer overflow interrupt is zero, see [Timer Overflow Interrupt](#);
- the channels interrupts are zero, see [Channel \(n\) Interrupt](#);
- the channels are in input capture mode, see [Input Capture mode](#);
- the channels outputs are zero;
- the channels pins are not controlled by FTM (ELS(n)B:ELS(n)A = 0:0) (See the table in the description of CnSC register).

The following figure shows the FTM behavior after the reset. At the reset (item 1), the FTM counter is disabled (see the description of the CLKS field in the Status and Control register), its value is updated to zero and the pins are not controlled by FTM (See the table in the description of CnSC register).

After the reset, the FTM should be configured (item 2). It is necessary to define the FTM counter mode, the FTM counting limits (MOD and CNTIN registers value), the channels mode and CnV registers value according to the channels mode.

Thus, it is recommended to write any value to CNT register (item 3). This write updates the FTM counter with the CNTIN register value and the channels output with its initial value (except for channels in output compare mode) ([Counter reset](#)).

The next step is to select the FTM counter clock by the CLKS[1:0] bits (item 4). It is important to highlight that the pins are only controlled by FTM when CLKS[1:0] bits are different from zero (See the table in the description of CnSC register).

**Figure 12-98. FTM behavior after reset when the channel (n) is in Combine mode**

The following figure shows an example when the channel (n) is in Output Compare mode and the channel (n) output is toggled when there is a match. In the Output Compare mode, the channel output is not updated to its initial value when there is a write to CNT register (item 3). In this case, use the software output control ([Software output control](#)) or the initialization ([Initialization](#)) to update the channel output to the selected value (item 4).

**Figure 12-99. FTM behavior after reset when the channel (n) is in Output Compare mode**

## 12.2.6 FTM Interrupts

### 12.2.6.1 Timer Overflow Interrupt

The timer overflow interrupt is generated when (TOIE = 1) and (TOF = 1).

### 12.2.6.2 Channel (n) Interrupt

The channel (n) interrupt is generated when (CHnIE = 1) and (CHnF = 1).

## 12.2.7 Initialization Procedure

The following initialization procedure is recommended to configure the FlexTimer operation. This procedure can also be used to do a new configuration of the FlexTimer operation.

- Define the POL bits.
- Mask the channels outputs using SYNCHOM = 0. Two clocks after the write to OUTMASK, the channels output are in the safe value.
- (Re)Configuration FTM counter and channels to generation of periodic signals - Disable the clock. If the selected mode is Quadrature Decoder, then disable this mode. Examples of the (re)configuration:

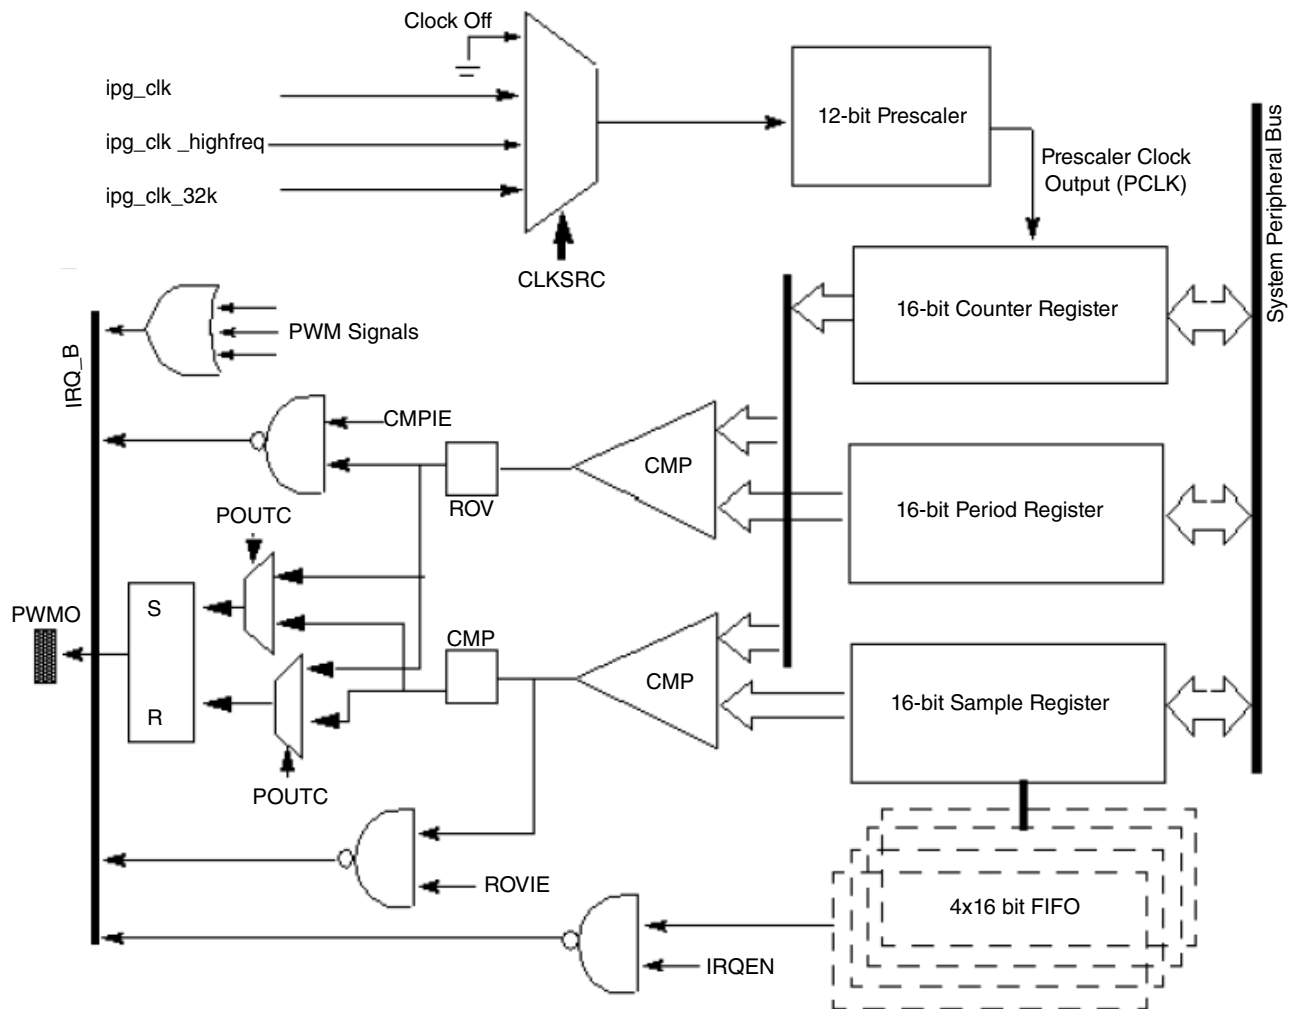

- Write to MOD.
- Write to CNTIN.
- Select OC, EPWM, CPWM, Combine, Complement modes for all channels that will be used
- Select the high-true and low-true channels modes.
- Write to CnV for all channels that will be used .
- (Re)Configure deadline.
- Do not use the SWOC without SW synchronization (see item 6).
- Do not use the Inverting without SW synchronization (see item 6).
- Do not use the Initialization.
- Do not change the polarity control.
- Do not configure the HW synchronization
- Write any value to CNT. The FTM Counter is reset and the channels output are updated according to new configuration.
- Enable the clock. Write to CLKS[1:0] bits a value different from zero. If in the Quadrature Decoder mode, enable this mode.
- Configure the SW synchronization for SWOC (if it is necessary), Inverting (if it is necessary) and Output Mask (always)
  - Select synchronization for Output Mask Write to SYNC (SWSYNC = 0, TRIG2 = 0, TRIG1 = 0, TRIG0 = 0, SYNCHOM = 1, REINIT = 0, CNTMAX = 0, CNTMIN = 0)
  - Write to SYNCONF.
    - HW Synchronization can not be enabled (HWSOC = 0, HWINVC = 0, HWOM = 0, HWRBUF = 0, HWRSTCNT = 0, HWTRIGMODE = 0).
    - SW Synchronization for SWOC (if it is necessary): SWSOC = [0/1] and SWOC = [0/1].
    - SW Synchronization for Inverting (if it is necessary): SWINVC = [0/1] and INVC = [0/1].
    - SW Synchronization for SWOM (always): SWOM = 1. No enable the SW Synchronization for write buffers (because the writes to registers with write buffer are done using CLKS[1:0] = 2'b00): SWWRBUF = 0 and CNTINC = 0 .
    - SW Synchronization for counter reset (always): SWRSTCNT = 1.
    - Enhanced synchronization (always): SYNCMODE = 1
  - If the SWOC is used (SWSOC = 1 and SWOC = 1), then write to SWOCTRL register.
  - If the Inverting is used (SWINVC = 1 and INVC = 1), then write to INVCTRL register.
  - Write to OUTMASK to enable the masked channels.
- Generate the Software Trigger Write to SYNC (SWSYNC = 1, TRIG2 = 0, TRIG1 = 0, TRIG0 = 0, SYNCHOM = 1, REINIT = 0, CNTMAX = 0, CNTMIN = 0)

## 12.3 Pulse Width Modulation (PWM)

### 12.3.1 Overview

The Pulse Width Modulation (PWM) has a 16-bit counter, and is optimized to generate sound from stored sample audio images and it can also generate tones. It uses 16-bit resolution and a 4 x 16 data FIFO.

This section presents an overview of the PWM. A block diagram of the PWM module is shown in the figure below.

**Figure 12-100. Pulse-Width Modulator Block Diagram**

The following features characterize the PWM:

## Pulse Width Modulation (PWM)

- 16-bit up-counter with clock source selection
- 4 x 16 FIFO to minimize interrupt overhead
- 12-bit prescaler for division of clock
- Sound and melody generation
- Active high or active low configured output
- Can be programmed to be active in low-power mode
- Can be programmed to be active in debug mode
- Interrupts at compare and rollover

### 12.3.2 External Signals

The PWM follows IP Bus protocol when interfacing with the processor core. PWM does not have any interface signals with any other block inside the chip except for clock and reset inputs from the Clock Control Module (CCM), System Reset Controller (SRC), and interrupt signals to the processor interrupt handler. There is a single output signal.

The following table outlines the external signals.

**Table 12-19. PWM External Signals**

Signal	Description	Pad	Mode	Direction
PWM1_OUT	This is the PWM1 functional output of the PWM. A modulated signal of the block is observed at this pin. It can be viewed as a clock signal whose period and duty cycle can be varied with different settings of the cycle of 50%.	ENET1_RDATA0	ALT1	O
		GPIO1_IO01	ALT1	
		GPIO1_IO08	ALT7	
PWM2_OUT	This is the PWM2 functional output of the PWM. A modulated signal of the block is observed at this pin. It can be viewed as a clock signal whose period and duty cycle can be varied with different settings of the cycle of 50%.	ENET1_RDATA1	ALT1	O
		GPIO1_IO02	ALT1	
		GPIO1_IO09	ALT7	
PWM3_OUT	This is the PWM3 functional output of the PWM. A modulated signal of the block is observed at this pin. It can be viewed as a clock signal whose period and duty cycle can be varied with different settings of the cycle of 50%.	ENET1_TDATA0	ALT1	O
		GPIO1_IO03	ALT1	
		GPIO1_IO10	ALT7	
PWM4_OUT	This is the PWM4 functional output of the PWM. A modulated signal of the block is observed at this pin. It can be viewed as a clock signal whose period and duty cycle can be varied with different settings of the cycle of 50%.	ENET1_TDATA1	ALT1	O
		GPIO1_IO00	ALT1	
		GPIO1_IO11	ALT7	

### 12.3.3 Clocks

The table found here describes the clock sources for PWM.

Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

**Table 12-20. PWM Clocks**

Clock name	Clock Root	Description
ipg_clk	ipg_clk_root	Peripheral clock
ipg_clk_32k	ckil_sync_clk_root	low-frequency reference clock (32 kHz)
ipg_clk_highfreq	perclk_clk_root	high-frequency reference clock
ipg_clk_s	ipg_clk_root	Peripheral access clock

The clock that feeds the prescaler can be selected from:

- High-frequency reference clock (ipg\_clk\_highfreq) pat\_ref or CKIH

This is a high frequency clock, provided by the Clock Control Module (CCM). This clock should be on in the low power mode when the ipg\_clk is turned off. Thus, the PWM can be run on this clock in the low power mode.

- Low-frequency reference clock (ipg\_clk\_32k, CKIL)

This is the 32 KHz low reference clock which is provided by the CCM. This clock should be on in the low power mode when ipg\_clk is turned off. Thus, PWM can be run on this clock in the low power mode.

- Peripheral clock (ipg\_clk)

This clock should be on in normal operations. In low power mode, it can be switched off.

- Peripheral access clock (ipg\_clk\_s)

This clock is used for register read/write.

The clock input source is determined by the PWM control register field PWM\_CR[CLKSRC]. The CLKSRC value should only be changed when the PWM is disabled.

A change in the value of the PRESCALER field of the control register is immediately reflected on its output clock frequency.

## 12.3.4 Functional Description

The following sections detail the PWM operation and function.

### 12.3.4.1 Operation

The output of the PWM is a toggling signal whose frequency and duty cycle can be modulated by programming the appropriate registers. It has a 16-bit up counter which counts from 0x0000 until the counter value equals the PWM\_PR + 1. After this match occurs the counter is reset to 0x0000.

At the beginning of a count period cycle, the PWM0 pin is set to one (default) and the counter begins counting up from 0x0000. The sample value in the sample FIFO is compared on each count of prescaler clock. When the sample and count values match, the PWM0 signal is cleared to zero (default). The counter continues counting until the period match occurs and subsequently another period cycle begins.

When the PWM is enabled, the counter starts running and generates an output with the reset values in the period and sample registers. It is recommended that the programming of these registers be done before PWM is enabled.

A hardware reset results in all the PWM count and sample registers being cleared and the FIFO being flushed. The control register shows that FIFO is empty and it can be written into, and the PWM is disabled. A software reset has the same results, however the state of the STOPEN, DOZEN, WAITEN, and DBGEN bits in the control register are not affected. Software reset can be asserted even when the PWM is in disabled state.

#### 12.3.4.1.1 FIFO

Digital sample values can be loaded into the pulse-width modulator as 16-bit words. The endianness can be changed using the BCTR and HCTR bits of the control register. A 4-word (16-bit) FIFO minimizes interrupt overhead. A maskable interrupt is generated when the number of data words fall below the water level set by the FWM field in the control register.

A write to the PWM\_SAR sample register results in the value being stored into the FIFO if it is not full. A write when the FIFO is full sets FWE (FIFO write error) bit in the status register and the FIFO contents remain unchanged. The FIFO can be written at any time, but can be read only when the PWM is enabled. The PWM\_SR[FIFOAV] field shows how many data words are currently contained in the FIFO and whether or not it can be written into.

A read on the sample register yields the current FIFO value that is being used, or will be used, by the PWM for generation on the output signal. Therefore, a write and a subsequent read on the sample register may result in different values being obtained.

#### 12.3.4.1.2 Rollover and Compare Event

The counter is reset to 0x0000 after its value equals the  $\text{PWM\_PR}[\text{PERIOD}] + 1$  and resumes counting thereafter. This event is referred to as a rollover. For example, if  $\text{PWM\_PR}[\text{PERIOD}] = 0x0000$ , the counter is reset when it equals 0x0001. When  $\text{PWM\_PR}[\text{PERIOD}] = 0xFFFF$  or 0xFFFE, the counter is reset when it equals 0xFFFF. For more information, see the PWM Period Register (PWM\_PR) description.

During a rollover event the output is either set (default), reset or has no effect according to the programming of the POUTC field in the control register. This event can also generate an interrupt if the respective interrupt enable bit is set in the control register.

When the counter value reaches the sample value, the output of the PWM is reset (default), set or has no effect according to the programming of the POUTC field of control register. This event is referred to as a compare event. This event can also generate an interrupt if the respective interrupt enable bit is set in the control register.

If the rollover event sets the PWM output signal, the compare event will reset it and vice versa for a particular programming configuration of POUTC field.

#### 12.3.4.1.3 Low Power Mode Behavior

In low power mode, if the clock from the selected clock source is available, the PWM counter continues to run and an output is produced, depending on whether the control bit for that mode is set or not. In the absence of the clock itself, or if the corresponding low power bit in the control register is 0, the counter is reset and resumes counting when it exits the low power mode.

#### 12.3.4.1.4 Debug Mode Behavior

In debug mode, PWM has the option of continuing to run or be halted. If the DBGGEN bit is not set in the PWM\_PWMCR, the PWM is halted. If the DBGGEN bit is set, then the PWM will continue to run in the debug mode.

### 12.3.5 Enable Sequence for the PWM

The sequence found here should be used to enable the PWM.

1. Configure the desired settings for the PWM Control Register (PWMx\_PWMCR) while keeping the PWM disabled (PWMx\_PWMCR[0]=0).
2. Enable the desired interrupts in the PWM Interrupt Register (PWMx\_PWMIR).
3. One to three initial samples may be written to the PWM Sample Register (PWMx\_PWMSAR). The initial sample values will be loaded into the PWM FIFO even if the PWM is not yet enabled. Do not write a 4th sample because the FIFO will become full and trigger a FIFO Write Error (FWE). This error will prevent the PWM from starting once it is enabled.
4. Check the FIFO Write Error status bit (FWE), the Compare status bit (CMP) and the Roll-over status bit (ROV) in the PWM Status Register (PWMx\_PWMSR) to make sure they are all zero. Any non-zero status bits should be cleared by writing a 1 to them.
5. Write the desired period to the PWM Period Register (PWMx\_PWMPR).
6. Enable the PWM by writing a 1 to the PWM Enable bit, PWMx\_PWMCR[0], while maintaining the other register bits in their previously configured state.

### 12.3.6 Disable Sequence for the PWM

The PWM can be disabled at any time by clearing the PWM enable bit, PWMx\_PWMCR[0] to 0.

Any data remaining in the FIFO will not be produced at the PWM output after the PWM has been disabled and will remain in the FIFO until the PWM is enabled again. A software reset (setting PWMx\_PWMCR[3] to 1) or a hardware reset will clear the FIFO and any remaining data will be lost.

### 12.3.7 PWM Memory Map/Register Definition

The PWM includes six user-accessible 32-bit registers.

**PWM memory map**

### 12.3.7.1 PWM Control Register (PWMx\_PWMCR)

The PWM control register (PWM\_PWMCR) is used to configure the operating settings of the PWM. It contains the prescaler for the clock division.

Address: Base address + 0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0				FWM		STOPEN	DOZEN	WAITEN	DBGEN	BCTR	HCTR	POUTC		CLKSRC	
W	0				FWM		STOPEN	DOZEN	WAITEN	DBGEN	BCTR	HCTR	POUTC		CLKSRC	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	PRESCALER												SWR	REPEAT	EN	
W	PRESCALER												SWR	REPEAT	EN	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### PWMx\_PWMCR field descriptions

Field	Description
31–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–26 FWM	FIFO Water Mark. These bits are used to set the data level at which the FIFO empty flag will be set and the corresponding interrupt generated  00 FIFO empty flag is set when there are more than or equal to 1 empty slots in FIFO 01 FIFO empty flag is set when there are more than or equal to 2 empty slots in FIFO 10 FIFO empty flag is set when there are more than or equal to 3 empty slots in FIFO 11 FIFO empty flag is set when there are more than or equal to 4 empty slots in FIFO
25 STOPEN	Stop Mode Enable. This bit keeps the PWM functional while in stop mode. When this bit is cleared, the input clock is gated off in stop mode. This bit is not affected by software reset. It is cleared by hardware reset.  0 Inactive in stop mode 1 Active in stop mode
24 DOZEN	Doze Mode Enable. This bit keeps the PWM functional in doze mode. When this bit is cleared, the input clock is gated off in doze mode. This bit is not affected by software reset. It is cleared by hardware reset.  0 Inactive in doze mode 1 Active in doze mode
23 WAITEN	Wait Mode Enable. This bit keeps the PWM functional in wait mode. When this bit is cleared, the input clock is gated off in wait mode. This bit is not affected by software reset. It is cleared by hardware reset.

Table continues on the next page...

## PWMx\_PWMCR field descriptions (continued)

Field	Description
	0 Inactive in wait mode 1 Active in wait mode
22 DBGEN	Debug Mode Enable. This bit keeps the PWM functional in debug mode. When this bit is cleared, the input clock is gated off in debug mode. This bit is not affected by software reset. It is cleared by hardware reset.  0 Inactive in debug mode 1 Active in debug mode
21 BCTR	Byte Data Swap Control. This bit determines the byte ordering of the 16-bit data when it goes into the FIFO from the sample register.  0 byte ordering remains the same 1 byte ordering is reversed
20 HCTR	Half-word Data Swap Control. This bit determines which half word data from the 32-bit IP Bus interface is written into the lower 16 bits of the sample register.  0 Half word swapping does not take place 1 Half words from write data bus are swapped
19–18 POUTC	PWM Output Configuration. This bit field determines the mode of PWM output on the output pin.  00 Output pin is set at rollover and cleared at comparison 01 Output pin is cleared at rollover and set at comparison 10 PWM output is disconnected 11 PWM output is disconnected
17–16 CLKSRC	Select Clock Source. These bits determine which clock input will be selected for running the counter. After reset the system functional clock is selected. The input clock can also be turned off if these bits are set to 00. This field value should only be changed when the PWM is disabled  00 Clock is off 01 ipg_clk 10 ipg_clk_highfreq 11 ipg_clk_32k
15–4 PRESCALER	Counter Clock Prescaler Value. This bit field determines the value by which the clock will be divided before it goes to the counter.  0x000 Divide by 1 0x001 Divide by 2 0xff Divide by 4096
3 SWR	Software Reset. PWM is reset when this bit is set to 1. It is a self clearing bit. A write 1 to this bit is a single wait state write cycle. When the block is in reset state this bit is set and is cleared when the reset procedure is over. Setting this bit resets all the registers to their reset values except for the STOPEN, DOZEN, WAITEN, and DBGEN bits in this control register.  0 PWM is out of reset 1 PWM is undergoing reset
2–1 REPEAT	Sample Repeat. This bit field determines the number of times each sample from the FIFO is to be used.  00 Use each sample once 01 Use each sample twice 10 Use each sample four times 11 Use each sample eight times

*Table continues on the next page...*

**PWMx\_PWMCR field descriptions (continued)**

Field	Description
0 EN	<p>PWM Enable. This bit enables the PWM. If this bit is not enabled, the clock prescaler and the counter is reset. When the PWM is enabled, it begins a new period, the output pin is set to start a new period while the prescaler and counter are released and counting begins.</p> <p>To make the PWM work with softreset and disable/enable, users can do software reset by setting the SWR bit, wait software reset done, configure the registers, and then enable the PWM by setting this bit to "1"</p> <p>Users can also disable/enable the PWM if PWM would like to be stopped and resumed with same registers configurations .</p> <p>0 PWM disabled 1 PWM enabled</p>

**12.3.7.2 PWM Status Register (PWMx\_PWMSR)**

The PWM status register (PWM\_PWMSR) contains seven bits which display the state of the FIFO and the occurrence of rollover and compare events. The FIFOAV bit is read-only but the other four bits can be cleared by writing 1 to them. The FE, ROV, and CMP bits are associated with FIFO-Empty, Roll-over, and Compare interrupts, respectively.

Address: Base address + 4h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0								FWE	CMP	ROV	FE	FIFOAV			
W									w1c	w1c	w1c	w1c				
Reset	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0

**PWMx\_PWMSR field descriptions**

Field	Description
31–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 FWE	<p>FIFO Write Error Status. This bit shows that an attempt has been made to write FIFO when it is full.</p> <p>0 FIFO write error not occurred 1 FIFO write error occurred</p>
5 CMP	<p>Compare Status. This bit shows that a compare event has occurred.</p> <p>0 Compare event not occurred 1 Compare event occurred</p>

Table continues on the next page...

## PWMx\_PWMSR field descriptions (continued)

Field	Description
4 ROV	Roll-over Status. This bit shows that a roll-over event has occurred.  0 Roll-over event not occurred 1 Roll-over event occurred
3 FE	FIFO Empty Status Bit. This bit indicates the FIFO data level in comparison to the water level set by FWM field in the control register.  0 Data level is above water mark 1 When the data level falls below the mark set by FWM field
FIFOAV	FIFO Available. These read-only bits indicate the data level remaining in the FIFO. An attempted write to these bits will not affect their value and no transfer error is generated.  000 No data available 001 1 word of data in FIFO 010 2 words of data in FIFO 011 3 words of data in FIFO 100 4 words of data in FIFO 101 unused 110 unused 111 unused

## 12.3.7.3 PWM Interrupt Register (PWMx\_PWMIR)

The PWM Interrupt register (PWM\_PWMIR) contains three bits which control the generation of the compare, rollover and FIFO empty interrupts.

Address: Base address + 8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
R	0																
W																	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
R	0														CIE	RIE	FIE
W																	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

## PWMx\_PWMIR field descriptions

Field	Description
31–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 CIE	Compare Interrupt Enable. This bit controls the generation of the Compare interrupt.

Table continues on the next page...

**PWMx\_PWMIR field descriptions (continued)**

Field	Description
	0 Compare Interrupt not enabled 1 Compare Interrupt enabled
1 RIE	Roll-over Interrupt Enable. This bit controls the generation of the Rollover interrupt. 0 Roll-over interrupt not enabled 1 Roll-over Interrupt enabled
0 FIE	FIFO Empty Interrupt Enable. This bit controls the generation of the FIFO Empty interrupt. 0 FIFO Empty interrupt disabled 1 FIFO Empty interrupt enabled

**12.3.7.4 PWM Sample Register (PWMx\_PWMSAR)**

The PWM sample register (PWM\_PWMSAR) is the input to the FIFO. 16-bit words are loaded into the FIFO. The FIFO can be written at any time, but can be read only when the PWM is enabled. The PWM will run at the last set duty-cycle setting if all the values of the FIFO has been utilized, until the FIFO is reloaded or the PWM is disabled. When a new value is written, the duty cycle changes after the current period is over.

A value of zero in the sample register will result in the PWMO output signal always being low/high (POUTC = 00 it will be low and POUTC = 01 it will be high), and no output waveform will be produced. If the value in this register is higher than the PERIOD + 1, the output will never be set/reset depending on POUTC value.

Address: Base address + Ch offset

**PWMx\_PWMSAR field descriptions**

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
SAMPLE	Sample Value. This is the input to the 4x16 FIFO. The value in this register denotes the value of the sample being currently used.

### 12.3.7.5 PWM Period Register (PWMx\_PWMPR)

The PWM period register (PWM\_PWMPR) determines the period of the PWM output signal. After the counter value matches PERIOD + 1, the counter is reset to start another period.

$$\text{PWMO (Hz)} = \text{PCLK(Hz)} / (\text{period} + 2)$$

A value of zero in the PWM\_PWMPR will result in a period of two clock cycles for the output signal. Writing 0xFFFF to this register will achieve the same result as writing 0xFFFE.

A change in the period value due to a write in PWM\_PWMPR results in the counter being reset to zero and the start of a new count period.

#### NOTE

Settings PWM\_PWMPR to 0xFFFF when PWMx\_PWMCR REPEAT bits are set to non-zero values is not allowed.

Address: Base address + 10h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																PERIOD															
W	0																1															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	0

#### PWMx\_PWMPR field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
PERIOD	Period Value. These bits determine the Period of the count cycle. The counter counts up to [Period Value] +1 and is then reset to 0x0000.

### 12.3.7.6 PWM Counter Register (PWMx\_PWMCNR)

The read-only pulse-width modulator counter register (PWM\_PWMCNR) contains the current count value and can be read at any time without disturbing the counter.

Address: Base address + 14h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																COUNT															
W	0																1															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**PWMx\_PWMCNR field descriptions**

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Counter Value. These bits are the counter register value and denotes the current count state the counter register is in.

# Chapter 13

## Multimedia

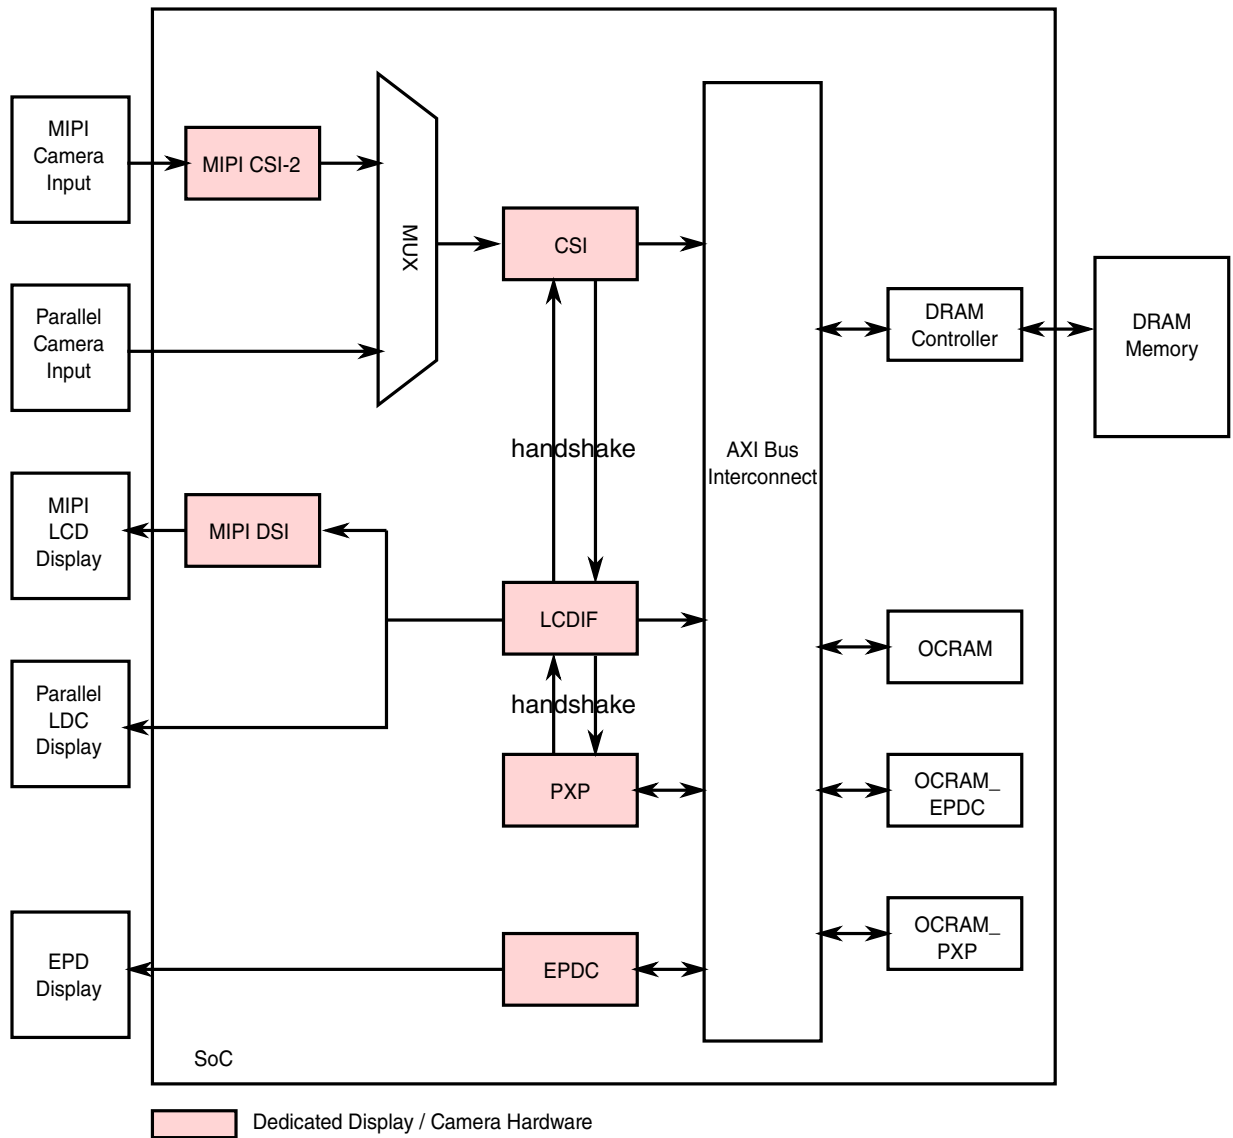

### 13.1 Multimedia

#### 13.1.1 Display and camera subsystem

The chip display and camera subsystem consists of the dedicated modules found here.

- EPDC (electrophoretic display controller): display controller for E-INK EPD panel
- LCD Interface (LCDIF): 24-bit parallel RGB LCD interface
- PXP pixel pipeline: pixel/image processing engine for EPD and LCD display
- CSI (camera sensor interface): up to 24-bit parallel interface for image sensor
- MIPI DSI Host controller with associated MIPI D-PHY Tx (one clock lane, two Data lanes)
- MIPI CSI-2 Host controller with associated MIPI D-PHY Rx (one clock lane, two Data lanes)

The following figure shows the high-level integration scheme of the chip display and camera system.

**Figure 13-1. Chip display and camera subsystem**

### 13.1.1.1 Electrophoretic Display Controller

The EPDC is a feature-rich, low power, and high-performance direct-drive active matrix EPD controller. It is specifically designed to drive E•INK™ EPD panels supporting a wide variety of TFT backplanes. The goal of the EPDC is to provide an efficient SoC integration of this functionality for e-paper applications, allowing a significant BOM cost saving over an external solution whilst reaching much higher levels of performance and lower power. The EPDC module is defined in the context of an optimized HW/SW partitioning and works in conjunction with the ePXP IP module to form a complete display processing solution.

The key features of the EPDC are as follows:

- Supports direct-driver for E-Ink EPD panels, with up to 2048x1536 resolution at 106 Hz refresh rate (or 4096x4096 resolution at 20 Hz refresh rate)
- Supports up to 64 LUT for concurrent update
- Supports automatic waveform selection based on both input image and current panel content
- Supports collision detection
- Supports arbitrary interface timing generator to support various display panels, such as PVI panels and LGD GIP panels.
- Supports per-pixel based update
- Supports up to 16-bit waveform index
- Supports up to 5-bit color depth (32 gray-scale)
- Supports both monochrome EPD panel and color EPD panel

### 13.1.1.2 PiXel Processing Pipeline

The pixel processing pipeline is used to perform image processing on image/video buffers before sending to an LCD display.

The main features of PXP include:

- Multiple input/output format support, including YUV/RGB/Grayscale
- Supports both RGB/YUV scaling
- Supports overlay with Alpha blending
- Supports 2D Blit operation
- Supports HW dithering with configurable dithering algorithm
- Single-pass pixel processing for scaling, alpha blending, CSC, rotation and dithering without multiple access to DRAM
- Supports flexible programmable pixel processing engine, which can be configured for advanced EPD waveform processing

### 13.1.1.3 LCD Interface

The LCDIF is a general purpose display controller that is used to drive a wide range of display devices. These displays can vary in size and capability. Many of these displays have had an asynchronous parallel MPU interface for command and data transfer to an integrated frame buffer. There are other popular displays that support moving pictures and require the RGB interface mode (called DOTCLK interface in this document) or the VSYNC mode for high-speed data transfers. In addition to these displays, it is also

common to provide support for digital video encoders that accept ITU-R BT.656 format 4:2:2 YCbCr digital component video and convert it to analog TV signals. The LCDIF block supports these different interfaces by providing fully programmable functionality.

The block has several major features:

- Bus master interface to source frame buffer data for display refresh and a DMA interface to manage input data transfers from the LCD requiring minimal CPU overhead.
- 8/16/18/24 bit LCD data bus support available depending on I/O mux options.
- Programmable timing and parameters for MPU, VSYNC and DOTCLK LCD interfaces to support a wide variety of displays.
- ITU-R BT.656 mode (called Digital Video Interface or DVI mode here) including progressive-to-interlace feature and RGB to YCbCr 4:2:2 color space conversion to support 525/60 and 625/50 operation.

#### 13.1.1.4 Parallel CMOS Sensor Interface

The CSI enables the chip to connect directly to external CMOS image sensors. CMOS image sensors are separated into two classes, dumb and smart. Dumb sensors are those that support only traditional sensor timing (Vertical SYNC and Horizontal SYNC) and output only Bayer and statistics data, while smart sensors support CCIR656 video decoder formats and perform additional processing of the image (for example, image compression, image pre-filtering, and various data output formats).

The capabilities of the CSI include:

- Configurable interface logic to support most commonly available CMOS sensors.
- Support for CCIR656 video interface as well as traditional sensor interface.
- 8-bit data port for YCC, YUV, or RGB data input.
- 8-bit/10-bit/16-bit/24-bit data port for generic data input.
- Full control of 8-bit/pixel, 10-bit/pixel or 16-bit/pixel data format to 64-bit receive FIFO packing.
- 256 × 64 FIFO to store received image pixel data. Receive FIFO overrun protection mechanism.
- Embedded DMA controllers to transfer data from receive FIFO or statistic FIFO through AHB bus.
- Support for 2D DMA transfer from the receive FIFO to the frame buffers in the external memory.
- Support for double buffering two frames in the external memory.
- Single interrupt source to interrupt controller from maskable interrupt sources:
  - Start of Frame

- End of Frame
- Change of Field
- FIFO full
- FIFO overrun
- DMA transfer done
- CCIR error
- AHB bus response error
- Configurable master clock frequency output to sensor.
- Statistic data generation for Auto Exposure (AE) and Auto White Balance (AWB) control of the camera (only for Bayer data and 8-bit/pixel format).

## 13.1.2 Display / Sensor MIPI interfaces

### 13.1.2.1 Introduction

i.MX Application Processor features MIPI DSI/CSI-2 interfaces that includes:

- MIPI DSI Host controller with associated MIPI D-PHY Tx (One clock lane, two Data lanes)
- MIPI CSI-2 Host controller with associated MIPI D-PHY Rx (one clock lane, Data Lanes)

### 13.1.2.2 MIPI DSI

MIPI DSI is a high performance serial interconnect bus for mobile applications connecting display system to the host system.

There is one instance of DSI port in the i.MX 7Dual application processor. This interface support from 80 Mbps up to 1.5 Gbps speed per data lane. The DSI Receiver core can manage one clock lane and up to 2 data lanes through the lane management, however two data lanes are implemented in the transmitter D-PHY, therefore the maximum throughput of display port is 3Gbps.

The DSI port supports the following standards:

- MIPI DSI Compliant
- DSI Version 1.01
- DPI Version 2.0
- DBI Version 2.0
- DCS Version 1.02

- PPI for D-PHY
- MIPI D-PHY Version 1.0

DSI host core is capable of supporting a variety of resolutions and formats:

- Resolution:
  - QQVGA
  - QCIF, QVGA
  - CIF
  - VGA
  - WVGA
  - SVGA
  - XVGA
  - WXGA
- Pixel format:
  - RGB565
  - LRGB565
  - RGB666
  - RGB888

The DSI can support both command and video modes and up to four virtual channels to accommodate multiple displays.

- Command and video mode support (type 1, 2, 3, and 4 display architecture)
- Mode switching: low power and ultra low power
- Burst mode: dual video channel
- Non-burst mode: single video channel
- Bus turnaround
- Fault error recovery scheme

DPI and DBI could coexist in the system but only one of them could be active in a certain time moment

### 13.1.2.3 MIPI CSI-2

MIPI CSI-2 is a high performance serial interconnect bus for mobile applications connecting camera sensors to the host system.

There is one instance of CSI-2 port in the i.MX 7Dual application processor. This interface support from 80 Mbps up to 1.5 Gbps speed per data lane. The CSI-2 Receiver core can manage one clock lane and up to two data lanes through the lane management and de-packetization, providing a maximum throughput of 3 Gbps transfer rate.

The CSI-2 port supports the following standards:

- MIPI CSI-2 Version 1.0
- MIPI PPI interface for D-PHY
- MIPI D-PHY Version 1.0

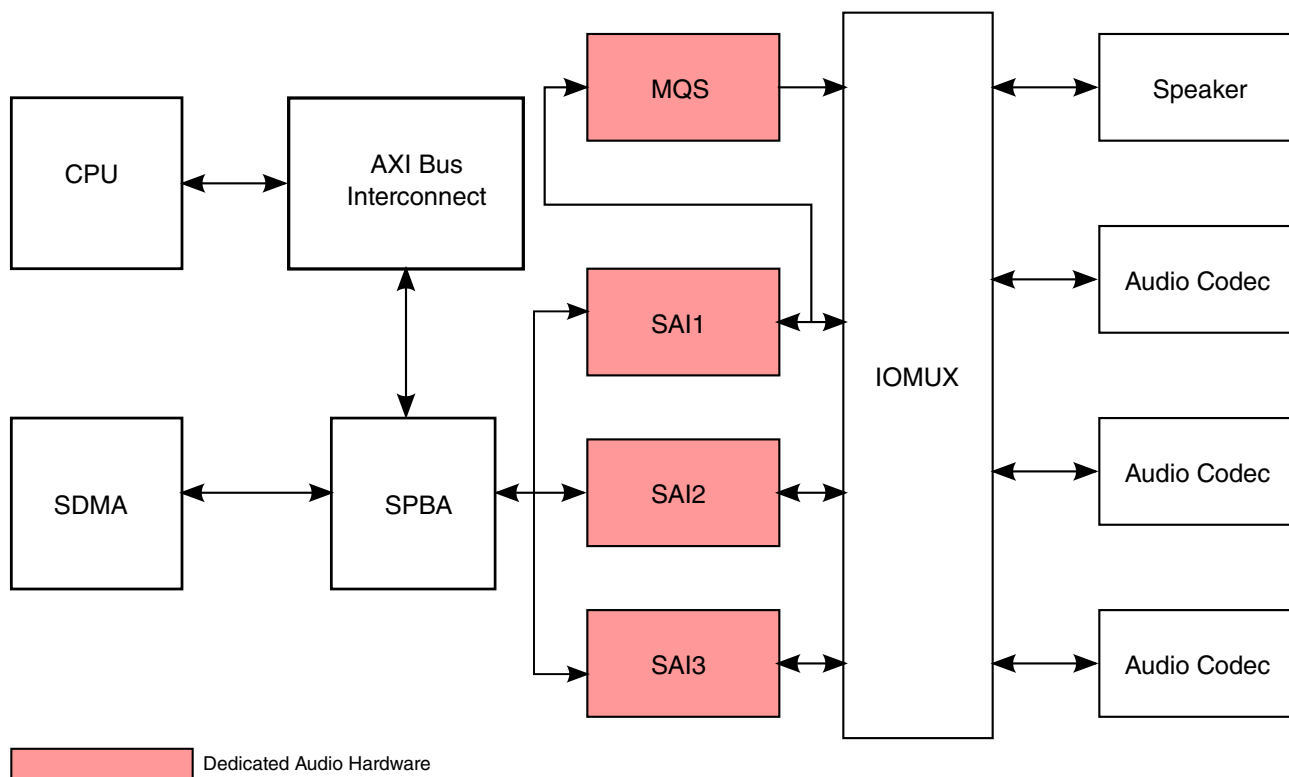

### 13.1.3 Audio subsystem

The audio subsystem consists of the following modules: SAI-1, SAI-2, SAI-3, and MQS. In addition, the IOMUX must be appropriately configured to get signals in and out of the chip.

[Audio Subsystem Module Overview](#) provides an overview of each of the audio subsystem component modules, followed by a module-specific section.

#### 13.1.3.1 Audio Subsystem Module Overview

The following figure shows a high level block diagram of the audio subsystem.

**Figure 13-2. Audio subsystem block diagram**

SAI1–3 are synchronous serial interfaces used to transfer audio data. SAI1–3 are on the shared peripheral bus. They can be accessed by both the SDMA and ARM CPUs. Their input/output are connected to the pads through IOMUX.

MQS (medium quality speaker) is used to convert the I2S audio data from SAI to PWM signals that can drive external speaker directly. Its audio source comes from SAI-1 and its output is connected to pads through IOMUX.

### 13.1.3.2 Synchronous Audio Interface (SAI)

- Transmitter with independent Bit Clock and Frame Sync supporting 1 data line
- Receiver with independent Bit Clock and Frame Sync supporting 1 data line
- Maximum Frame Size of 32 Words
- Word size programmable from 8-bits to 32-bits
- Word size configured separately for first word and remaining words in frame.
- Asynchronous FIFO for each Transmit and Receive data line
- Graceful restart after FIFO Error

## 13.2 Enhanced LCD Interface (eLCDIF)

### 13.2.1 Overview

The eLCDIF is a general purpose display controller used to drive a wide range of display devices varying in size and capability.

Many of these displays have had an asynchronous parallel MPU interface for command and data transfer to an integrated frame buffer. There are other popular displays that support moving pictures and require the RGB interface mode (called DOTCLK interface in this document) or the VSYNC mode for high-speed data transfers. In addition to these displays, it is also common to provide support for digital video encoders that accept ITU-R BT.656 format 4:2:2 YCbCr digital component video and convert it to analog TV signals. The eLCDIF block supports these interfaces by providing fully programmable functionality.

The block has several major features:

- Bus master interface to source frame buffer data for display refresh. This interface can also be used to drive data for "Smart" displays.
- PIO interface to manage data transfers between "Smart" displays and SoC.
- 8/16/18/24/32 bit LCD data bus support available depending on I/O mux options.

- Programmable timing and parameters for MPU, VSYNC and DOTCLK LCD interfaces to support a wide variety of displays.
- ITU-R BT.656 mode (called Digital Video Interface or DVI mode here) including progressive-to-interlace feature and RGB to YCbCr 4:2:2 color space conversion to support 525/60 and 625/50 operation.

## 13.2.2 External Signals

The following table describes the external signals of LCD:

**Table 13-1. LCD External Signals**

Signal	Description	Pad	Mode	Direction
LCD_BUSY	Busy Signal	EPDC1_DATA08	ALT7	I
		EPDC1_GDSP	ALT6	
LCD_CLK	Clock Signal	EPDC1_DATA00	ALT7	I

### 13.2.3 Clocks

The following table describes the clock sources for eLCDIF. Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

Table 13-2. eLCDIF Clocks

Clock name	Clock Root	Description
apb_clk	MAIN_AXI_CLK_ROOT	AXI clock
pix_clk	LCDIF_PIXEL_CLK_ROOT	Pixel clock
ipg_clk_s	MAIN_AXI_CLK_ROOT	Peripheral access clock

### 13.2.4 Functional Description

Bus Interface Mechanisms through [Initializing the eLCDIF](#), describe the internal pipeline for the MPU write/read interface, VSYNC, DOTCLK, and DVI interfaces. Differences for each mode are then described in separate sections, as follows:

- [MPU Interface](#)
- [VSYNC Interface](#)
- [DOTCLK Interface](#)
- [ITU-R BT.656 Digital Video Interface \(DVI\)](#)

eLCDIF pin usage by interface mode is described in [eLCDIF Pin Usage by Interface Mode](#).

Figure 13-3. Top-Level Block Diagram of eLCDIF subsystem

### 13.2.4.1 Bus Interface Mechanisms

The LCDIF module has memory-mapped control, data and status registers. It provides several interfaces to transfer data between the display and SoC.

The bus master interface is used to initiate the requests to transfer data from external memory to the display. It is completely autonomous, or no CPU intervention is required, to manage the cyclical nature of refreshing standard display types. Bus mastering can also be used for MPU mode data writes.

The PIO interface is used to interface to "Smart" displays to transfer frame buffer data and control information to/from the external display. The host CPU executes display drivers to manage the display solution.

The following sections describe the system bus interface mechanisms.

#### 13.2.4.1.1 Bus Master Operation in Write/Display Modes

The eLCDIF block has a bus master interface that initiates requests for data to drive the display. The LCDIF\_MASTER bit must be set to 1 to enable the bus master interface. Software should program all control registers required to transfer the frame sequence.

In the MPU and VSYNC modes, single frames are transferred. When a complete frame is transferred, eLCDIF enters idle and clears the RUN bit in the CTRL register. For subsequent frame transmission, the eLCDIF setup sequence should be repeated.

The DOTCLK and DVI modes are used to refresh the display at the desired refresh rate and resolution. These modes are used to drive displays that do not integrate a display buffer memory. When the display is refreshed, the eLCDIF will automatically update the LCDIF\_CUR\_BUF\_ADDR register with the value in LCDIF\_NEXT\_BUF\_ADDR at the end of current frame and start fetching the next frame from the new address. If the LCDIF\_NEXT\_BUF\_ADDR register was not updated within a frame refresh cycle, eLCDIF will keep transmitting the last frame until a new value is programmed into that register.

eLCDIF also provides the capability of interlacing a progressive frame by fetching odd lines in the first field and then fetching even lines in the second field. This feature can be used in the DVI mode and can be turned on by setting the INTERLACE\_FIELDS bit in the LCDIF\_CTRL1 register.

### 13.2.4.1.2 System Bus Master Performance

The performance of the eLCDIF block can be controlled by changing the burst length and the outstanding cycle issuing capability depending on the memory bandwidth requirements. Two fields in the LCDIF\_CTRL2 register will throttle system memory requests. The LCDIF\_CTRL2\_OUTSTANDING\_REQS field will control how many requests the eLCDIF can have in flight on any given clock cycle. This should be programmed based on the expected system bus latency for returned read data. Also, the LCDIF\_CTRL2\_BURST\_LEN\_8 bit will set the number of 64 bit words requested for each eLCDIF system bus request to either 8 or 16 QWORDS. Generally, 4 outstanding requests of length 16 will provide enough performance to drive any standard display resolution. These configuration bits are intended to change the access pattern of the eLCDIF to optimize system bus throughput when other system masters will contend for system memory resources.

The LCDIF\_THRES register can also be used to optimize bus throughput and power consumption.

The LCDIF\_THRES\_PANIC value can be used to raise the priority of requests initiated by the eLCDIF to alter how the eLCDIF requests are arbitrated by the system bus infrastructure. The panic output control signal is raised when the number of 32bpp pixel equivalents in the LFIFO is less than this programmed value. Since the LFIFO is arranged as a 256x64bit quadword FIFO, it contains two 32bpp pixels per quadword, or 512 32bpp pixels total. To set the panic output when 3/4s of the LFIFO is empty, set the LCDIF\_THRES\_PANIC value to  $3/4 * 512$ , or 128. The panic signal output is used to assess higher priority to eLCDIF system requests to avoid eLCDIF under run errors during periods of high system bandwidth utilization.

The features available with the LCDIF\_THRES register require support from system clocking and dynamic priority control. Refer to the appropriate block documentation to assess the system support for these features.

### 13.2.4.2 Write Data Path

eLCDIF supports raster based frame buffers and there is no support for tiled buffers.

There are several options to accommodate endianness of display buffers in memory before the data is processed for the external display. The INPUT\_DATA\_SWIZZLE field in the LCDIF\_CTRL register provides the following options for data word multiplexing:

```
00 (0): No swizzle (little-endian)
01 (1): Swap bytes 0 and 3, swap bytes 1 and 2 (big-endian)
10 (2): Swap half-words
11 (3): Swap bytes within each half-word
```

The `WORD_LENGTH` field of `LCDIF_CTRL` register indicates the input data/pixel format. `LCDIF_TRANSFER_COUNT` register denotes how much data is contained in each frame. The `H_COUNT` field of this register indicates the number of pixels per line and `V_COUNT` indicates the total number of lines per frame. A special bit field in the `LCDIF_CTRL1` register, called the `BYTE_PACKING_FORMAT`, can be used to specify which bytes within the 32-bit word are going to be valid. For example, if the entire 32-bit word is valid, `BYTE_PACKING_FORMAT` should be set to `0xF`, if only lower 3 bytes of each word in the frame buffer are valid, then `BYTE_PACKING_FORMAT` should be set to `0x7`.

The `LCD_DATABUS_WIDTH` field in `LCDIF_CTRL` register suggests the width of the bus going to the external display controller. There is an option to source all 32 bits of the input word and transfer it to the output I/O display interface. Refer to the system I/O muxing options for support of this feature. If the `LCD_DATABUS_WIDTH` is not the same as `WORD_LENGTH`, eLCDIF will perform RGB to RGB color space conversion. For example, if the input frame has fewer bits per pixel than the display, as in a 16 bpp input frame going to 24 bpp LCD, eLCDIF will pad the MSBs of each color to the LSBs of the same color for each pixel. If the input frame has more bits per pixel than the display, for example, 24 bpp input frame going to 16 bpp LCD, eLCDIF will drop the LSBs of each color channel to convert to the lower color depth. eLCDIF also has the capability to support delta pixel displays by swizzling the R, G and B colors of each pixel in the odd and even lines of the frame separately by programming the `ODD_LINE_PATTERN` and the `EVEN_LINE_PATTERN` bit fields. This operation occurs after the RGB-to-RGB color space conversion operation.

eLCDIF also supports RGB to YCbCr 4:2:2 color space conversion. This is useful in the DVI mode since the TV encoder requires input in YCbCr 4:2:2 format. The `LCDIF_CSC*` registers have complete programmability over the CSC coefficients and offsets. The values must be written into these registers in the signed two's complement format.

The following list shows how the different input/output combinations can be obtained:

- `WORD_LENGTH=1` indicates that the input is 8-bit data. This is most likely going to be used for sending commands in MPU interface, or maybe a gray scale image. Any combination of `BYTE_PACKING_FORMAT` [3:0] is permissible.

Limitation: `H_COUNT` must be a multiple of the sum of `BYTE_PACKING_FORMAT` [3], `BYTE_PACKING_FORMAT` [2], `BYTE_PACKING_FORMAT` [1] and `BYTE_PACKING_FORMAT` [0].  
`LCD_DATABUS_WIDTH` must be 1, indicating an 8-bit data bus.

- `WORD_LENGTH=0` implies the input frame buffer is RGB 16 bits per pixel. `DATA_FORMAT_16_BIT` field determines the pixels are RGB 555 or RGB 565.

Limitation: `BYTE_PACKING_FORMAT` [3:0] should be 0x3 or 0xC if there is only one pixel per word. If there are two pixels per word, it should be 0xF and `H_COUNT` will be restricted to be a multiple of 2 pixels.

- `WORD_LENGTH=2` indicates that input frame buffer is RGB 18 bits per pixel, that is, RGB 666. The valid RGB values can be left-aligned or right-aligned within a 32-bit word. The alignment of the valid 18 bits within a word is indicated by the `DATA_FORMAT_18_BIT` bit.

Limitation: `BYTE_PACKING_FORMAT` can be 0x7, 0xE or 0xF. Packed pixels are not supported in this case. `H_COUNT` can be any number.

- `WORD_LENGTH=3` indicates that the input frame-buffer is RGB 24 bits per pixel (RGB 888). If `BYTE_PACKING_FORMAT` [3:0] is 0x7, it indicates that there is only one pixel per 32-bit word and there is no restriction on `H_COUNT`. This is also the option that provides 32 bit output depending on the I/O muxing options available. The fourth byte, or bits [31:24], and connected to the I/Os if this muxing is available in the chip package.

Limitation: If `BYTE_PACKING_FORMAT` [3:0] is 0xF, it indicates that the pixels are packed, that is, there are 4 pixels in 3 words or 12 bytes and `H_COUNT` must be a multiple of 4 pixels.

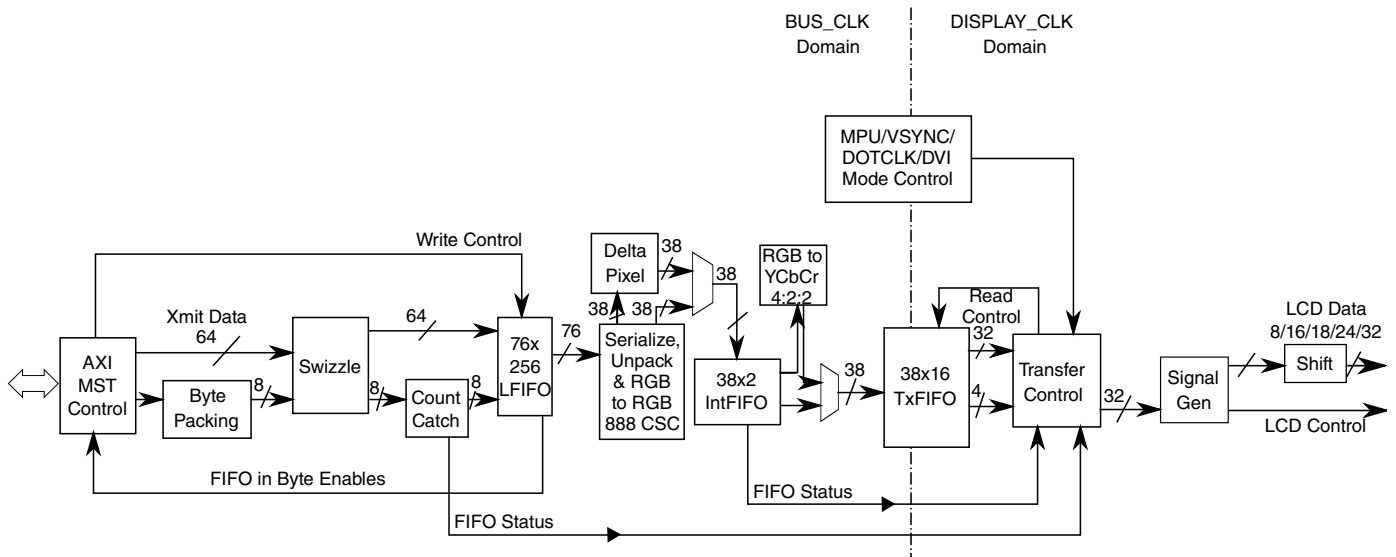

- `YCBCR422_INPUT=1` implies that the input frame is in YCbCr 4:2:2 format. `BYTE_PACKING_FORMAT` must be 0xF.

Limitation: `LCD_DATABUS_WIDTH` must be 8-bit and `H_COUNT` must be a multiple of 2 pixels.

`ODD_LINE_PATTERN` and `EVEN_LINE_PATTERN` must be 0 when any of `RGB_TO_YCBCR422_CSC` or `INTERLACE_FIELDS` or `YCBCR422_INPUT` bits is 1.

After the RGB to RGB or RGB to YCbCr 4:2:2 color space conversions, there is one more opportunity to swizzle the data before sending it out to the display or the encoder. This can be done with the `CSC_DATA_SWIZZLE` field in the `LCDIF_CTRL` register, and it provides the same options as the `INPUT_DATA_SWIZZLE` register.

Finally, there is an option to shift the output data before sending it out to the display. This is done based on the `SHIFT_DIR` and `SHIFT_NUM_BITS` fields in `LCDIF_CTRL` register.

**Figure 13-4. General Operations in Write Data Path**

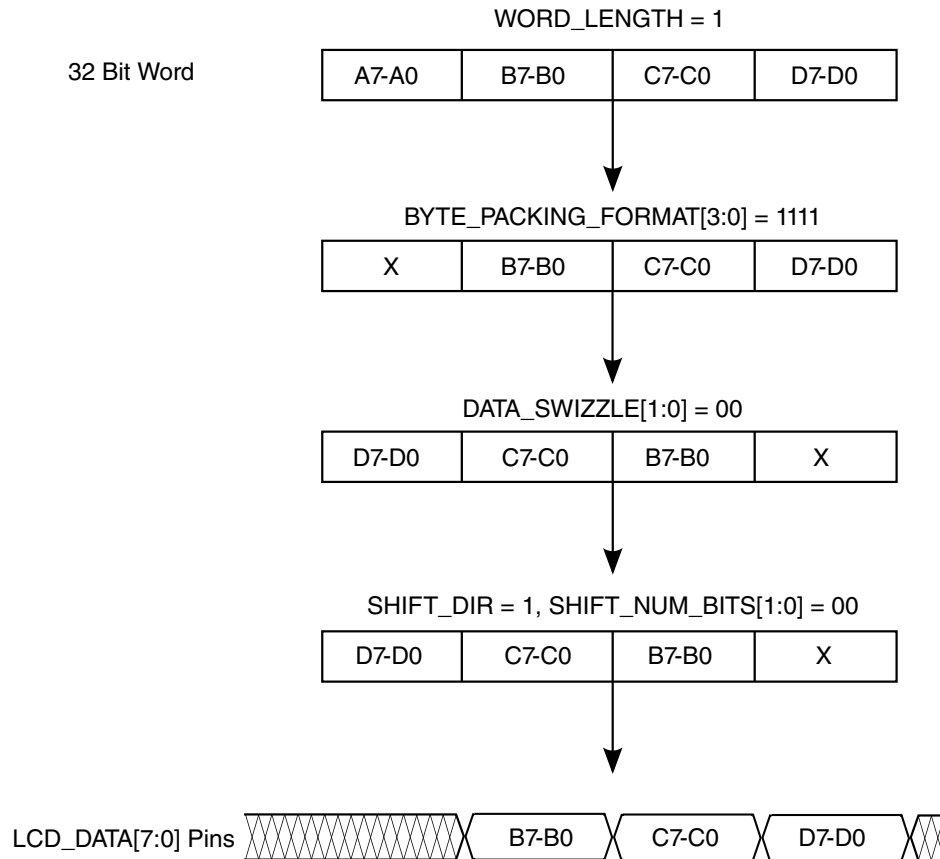

The examples in the following figures illustrate some different combinations of register programming for write mode. Assume that the data transferred over the system bus within a 32 bit word is organized as {A7-A0, B7-B0, C7-C0, D7-D0} in 8-bit mode and {A15-A0, B15-B0} in 16-bit mode.

In this example, all 32 bits of the input word are transferred out over an 8 bit display bus. Each byte within the 32 bit word is shifted to the right with zeros appended to I/O bits D[7:6]. The input data bits [7:2] are shifted to the right by 2 bits and presented on the D[5:0].

**Figure 13-5. Register programming for write mode**

In this 8 bit display interface example, one byte of the input word is deleted and not transferred over the external 8 bit display interface. This mode could be used to transfer 24bpp pixels over the 8 bit interface. In this case, the 4th unused byte is not transferred.

**Figure 13-6. Register programming for write mode**

The following example uses a 16 bit display interface. Each 16 bit half word is shifted to the right by two bits with zeros appended to the most significant two bits.

**Figure 13-7. Register programming for write mode**

This example indicates how an unpacked frame buffer can be sourced for display. Only a single 16-bit half word within the 32-bit word is transferred out via the 16-bit display bus.

**Figure 13-8. Register programming for write mode**

### 13.2.4.3 Read Data Path

Figure 13-9 shows the MPU read data path in detail.

eLCDIF can read from an external display that follows the 6800/8080 MPU protocol.

The display bus width is determined by the `LCD_DATABUS_WIDTH` bit field. The data sampled at every read strobe is called a subword and the number of subwords that can be packed in a 32-bit word is given by the `READ_MODE_NUM_PACKED_SUBWORDS` bit field. The `INITIAL_DUMMY_READ` bit field directs the eLCDIF to skip the number of programmed subwords before starting to process read data. This feature is useful in the case of an LCD controller that returns the last written data the first time a read is issued, and then sends the correct data thereafter. `SHIFT_DIR` and `SHIFT_NUM_BITS` bit fields indicate whether the data needs to be shifted before getting stored in the internal registers. For example, a value of 2 in `READ_MODE_NUM_PACKED_SUBWORDS` if lcd databus width is 8 bits indicates two bytes should be packed in a 32-bit word, while if the lcd databus width is 16 bits, it indicates that two half words (or 4 bytes) should be packed.

**Figure 13-9. MPU Read Data Path**

After the last subword within a word is reached, the block looks at the `READ_PACK_DIR` in the `HW_LCDIF_CTRL2` register. If this bit is set, the block will swizzle the data, but only within the valid bytes, unlike in the write mode, where swizzle occurs across all 4 bytes. If the `READ_MODE_OUTPUT_IN_RGB_FORMAT` bit is set, eLCDIF will convert the data obtained from the `READ_PACK_DIR` operation into 24-bit unpacked RGB and then re-convert it into 16/18/24 bpp RGB depending on the `WORD_LENGTH` field. The `DATA_FORMAT_16/18/24_BIT` bit fields are also considered while converting to 24-bit unpacked RGB format. For example, if `DATA_FORMAT_18_BIT` is 1, the RGB666 data will be packed in the upper bits [31:4] of a 32-bit word, and that bit is 0, the data will be packed in the lower bits [17:0]. After all these operations, the data gets written into the RXFIFO.

The following figures show some examples of how data is handled in different MPU read modes.

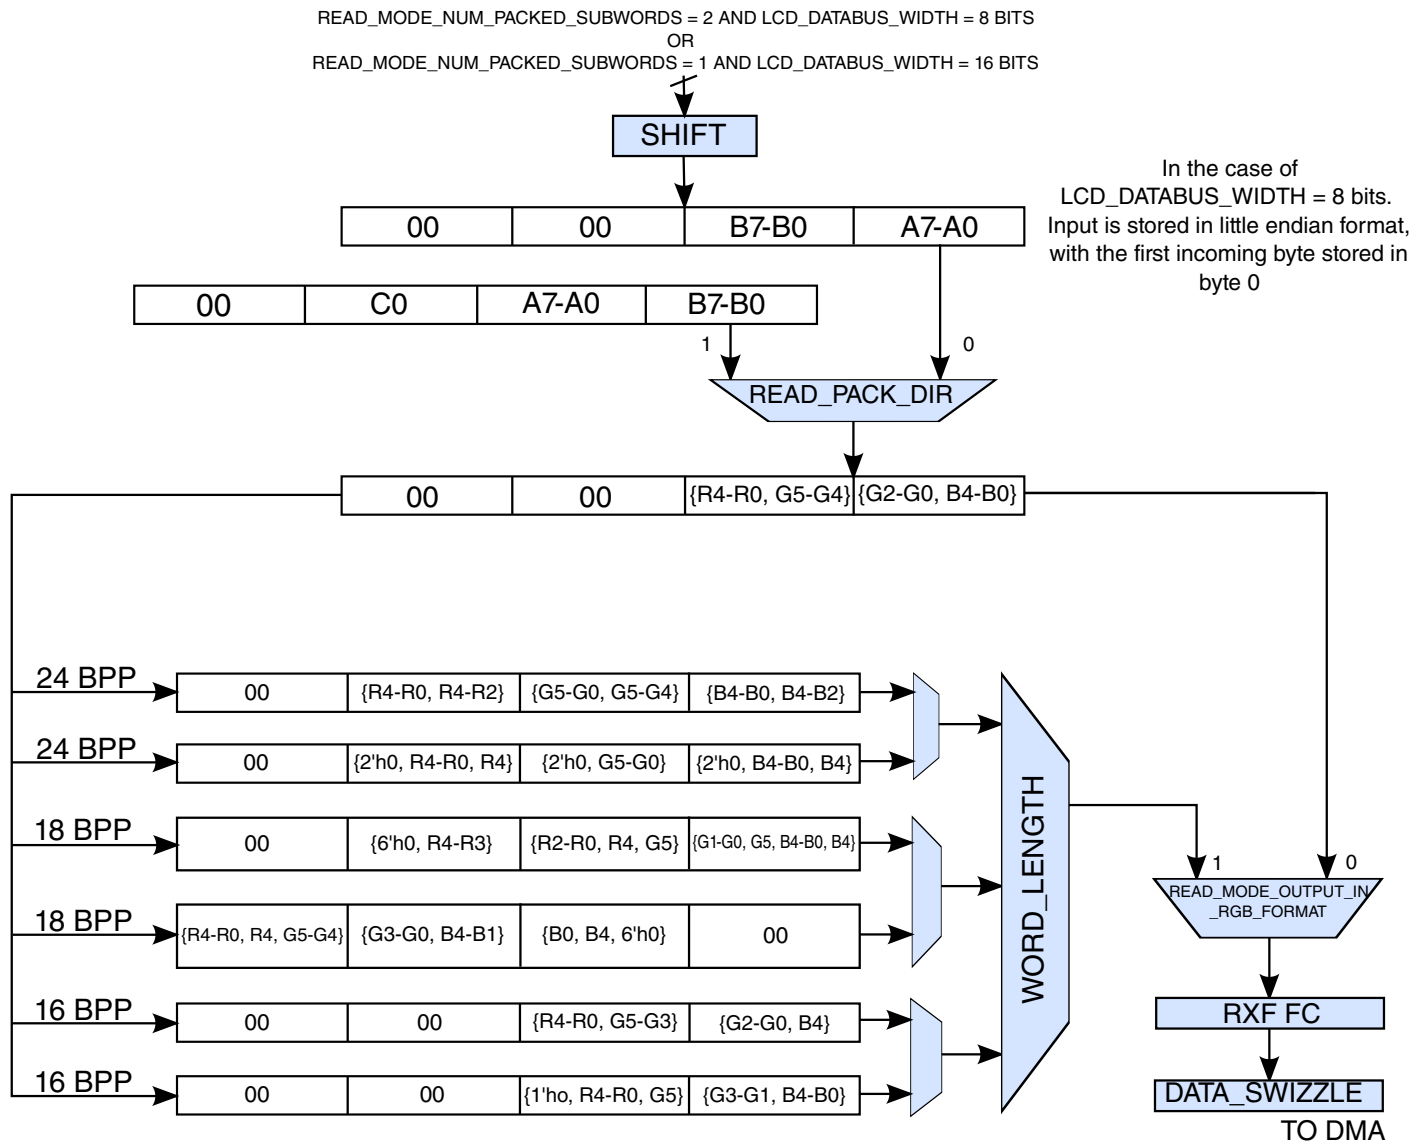

Figure 13-10. Data in MPU read mode

## Enhanced LCD Interface (eLCDIF)

READ\_MODE\_NUM\_PACKED\_SUBWORDS = 3 AND LCD\_DATABUS\_WIDTH = 8 BITS  
 OR  
 READ\_MODE\_NUM\_PACKED\_SUBWORDS = 1 AND LCD\_DATABUS\_WIDTH = 24 BITS

8/24

SHIFT

00 | C7-C0 | B7-B0 | A7-A0

00 | A7-A0 | B7-B0 | C7-C0

1

0

READ\_PACK\_DIR

00 | R7-R0 | G7-G0 | B7-B0

In the case of LCD\_DATABUS\_WIDTH = 8 bits. Input is stored in little endian format, with the first incoming byte stored in byte 0

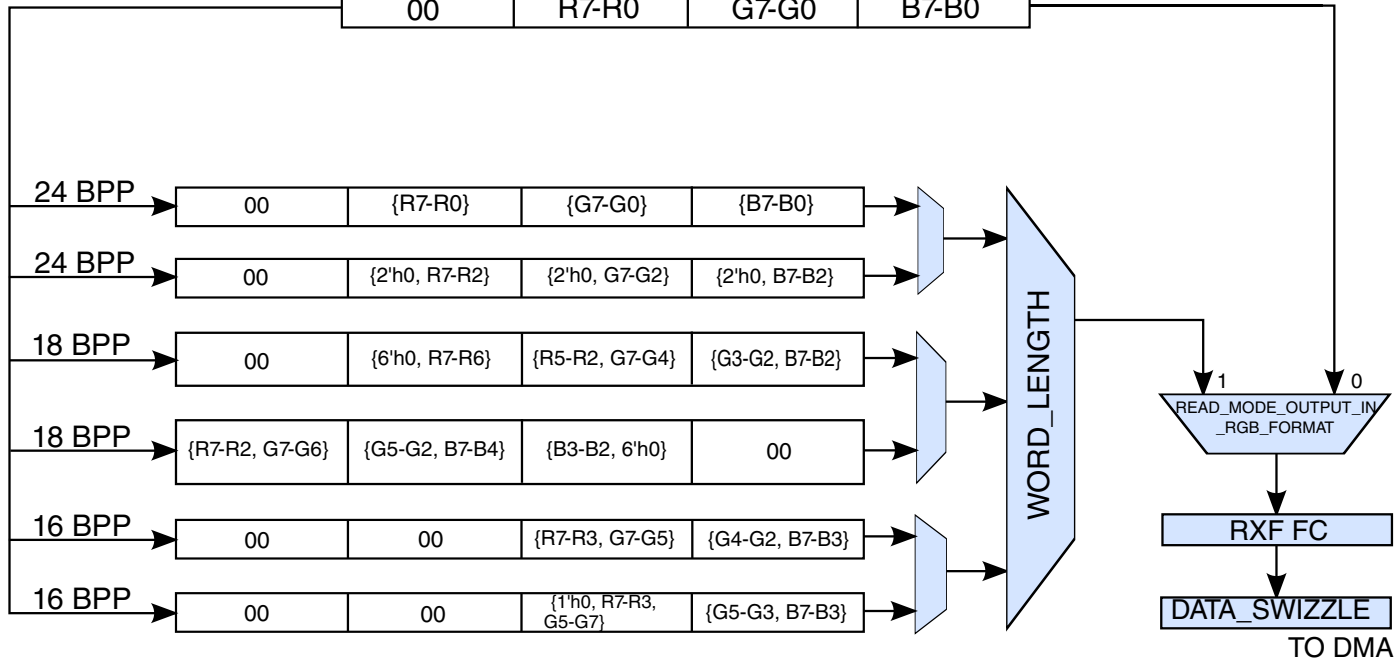

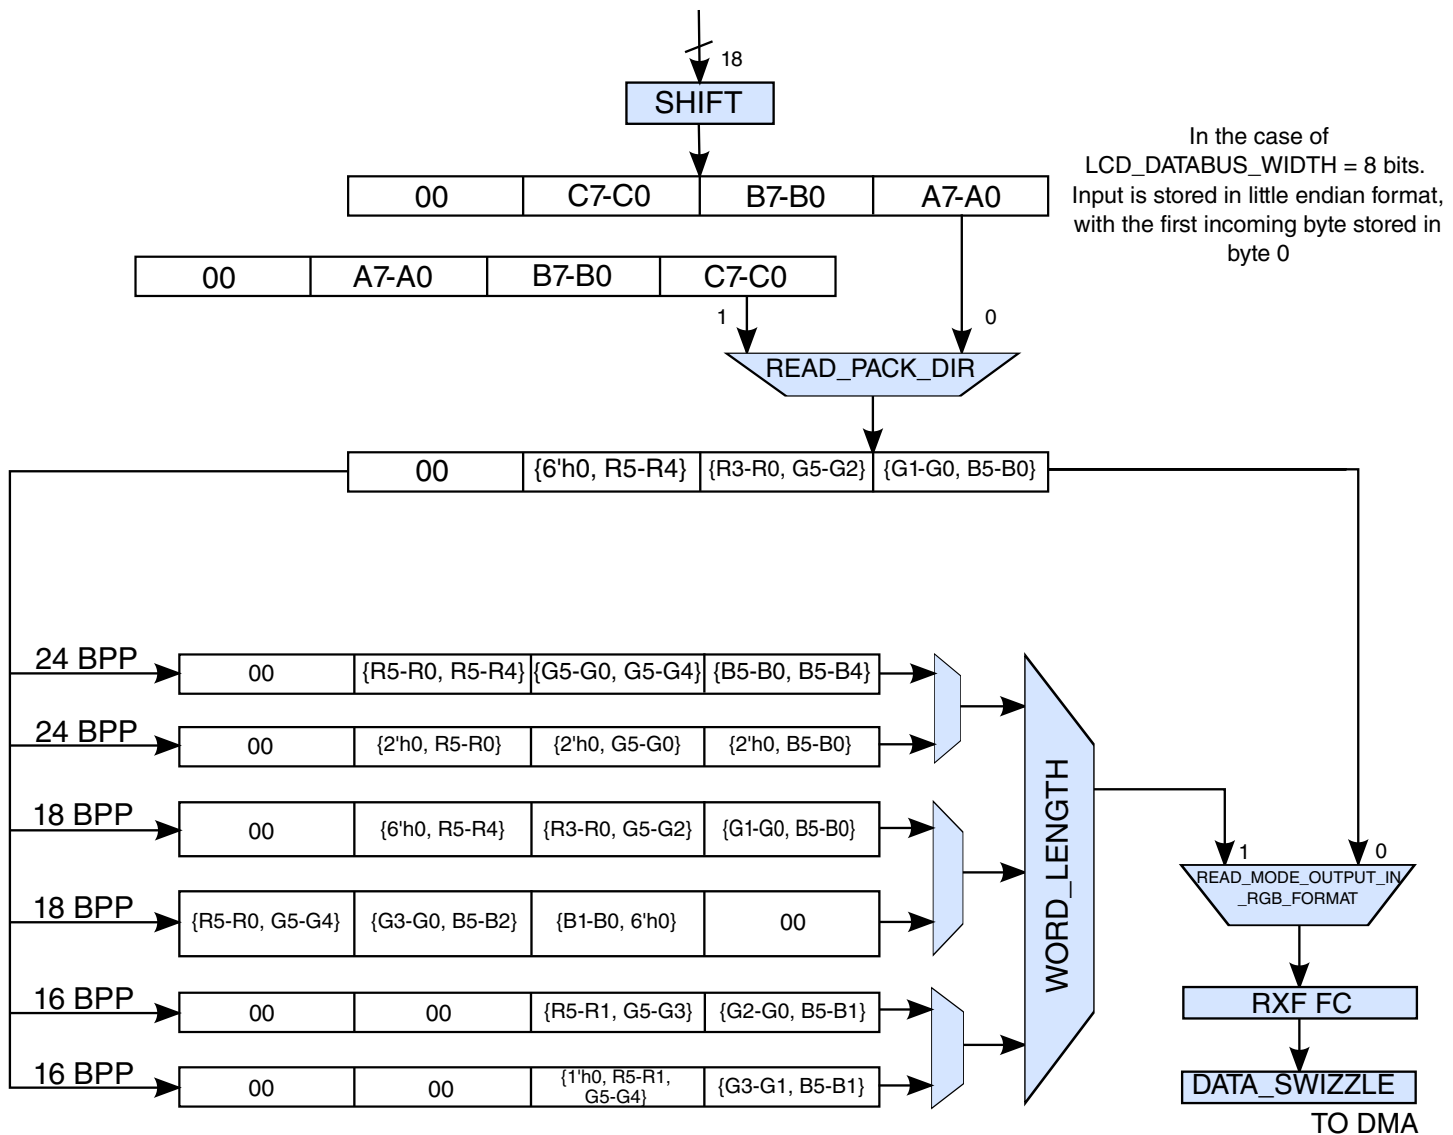

Figure 13-11. Data in MPU read mode

READ\_MODE\_NUM\_PACKED\_SUBWORDS = 1 AND LCD\_DATABUS\_WIDTH = 18 BITS

**Figure 13-12. Data in MPU read mode**

#### Restrictions:

READ\_PACK\_DIR should only be used if it is required to swizzle the subwords before doing RGB to RGB CSC, otherwise the DATA\_SWIZZLE field should be used to swizzle across bytes.

READ\_PACK\_DIR must be 0 if LCD\_DATABUS\_WIDTH is 8 bits and READ\_MODE\_NUM\_PACKED\_SUBWORDS = 1

If READ\_MODE\_OUTPUT\_IN\_RGB\_FORMAT bit is set, the following restrictions should be followed:

- If LCD\_DATABUS\_WIDTH = 8 bits, then  
READ\_MODE\_NUM\_PACKED\_SUBWORDS <= 3.
- If LCD\_DATABUS\_WIDTH = 16/18/24 bits, then  
READ\_MODE\_NUM\_PACKED\_SUBWORDS = 1.

### 13.2.4.4 eLCDIF Interrupts

eLCDIF supports a number of interrupts to aid controlling and status reporting of the block.

All the interrupts have individual mask bits for enabling or disabling each of them. They all get funneled through a single interrupt line connected to the interrupt collector (ICOLL).

The following list describes the different interrupts supported by eLCDIF:

- Underflow interrupt is asserted when the clock domain crossing FIFO (TXFIFO) becomes empty but the block is in active display portion during that time. Software should take corrective action to make sure that this does not happen.
- In the bus master mode, the overflow interrupt will be asserted if the block has requested more data than its FIFOs could hold. In the read mode, it will be asserted if the RxFIFO becomes full and the block reads more data.
- VSYNC edge interrupt will be asserted every time a leading VSYNC edge occurs.
- Cur\_frame\_done interrupt occurs at the end of every frame in all modes except DVI. In DVI mode, if IRQ\_ON\_ALTERNATE\_FIELDS bit is set, it will occur at the end of every frame, otherwise it will occur at the end of every field.

### 13.2.4.5 Initializing the eLCDIF

This section describes write modes and MPU read mode.

#### 13.2.4.5.1 Write Modes

The following initialization steps are common to all eLCDIF write modes of operation before entering any particular mode.

Initialization steps:

1. Configure the external I/Os to correctly interface the external display.
2. Start the DISPLAY\_CLK clock and set the appropriate frequency by programming the registers in CCM.

3. Start the BUS\_CLK and set the appropriate frequency by programming the registers in CCM.
4. Bring the eLCDIF out of soft reset and disable the clock gate bit.
5. Reset the LCD controller by setting LCDIF\_CTRL1\_RESET bit appropriately, being careful to observe the reset requirements of the controller. See [Behavior During Reset](#) for more information on Reset requirements.
6. Make sure READ\_WRITEB bit in HW\_LCDIF\_CTRL register is 0.
7. Select the transfer mode of operation. The LCDIF\_MASTER bit in HW\_LCDIF\_CTRL register determines the transfer mode selected. Bus master (LCDIF\_MASTER =1) or PIO (LCDIF\_MASTER =0) mode are the transfer modes to select.
8. Set the INPUT\_DATA\_SWIZZLE according to the endianness of the LCD controller. Also, set the DATA\_SHIFT\_DIR and SHIFT\_NUM\_BITS if it is required to shift the data left or right before it is output.
9. Set the WORD\_LENGTH field appropriately: 0 = 16-bit input, 1 = 8-bit input, 2 = 18-bit input, 3 = 24/32-bit input. Also, select the correct 16/18/24 bit data format with the corresponding fields in HW\_LCDIF\_CTRL register.
10. Set the BYTE\_PACKING\_FORMAT field in HW\_LCDIF\_CTRL1 according to the input frame.
11. Set the LCD\_DATABUS\_WIDTH appropriately: 0 = 16-bit output, 1 = 8-bit output, 2 = 18-bit output, 3 = 24/32-bit output.
12. Enable the necessary IRQs.

#### 13.2.4.5.2 MPU Read Mode

The following initialization steps should be done to enter the MPU read mode of operation:

Initialization steps:

1. Configure the external I/Os to correctly interface the external display.
2. Start the DISPLAY\_CLK and set the appropriate frequency by programming the registers in CCM.
3. Start the BUS\_CLK and set the appropriate frequency by programming the registers in CCM.
4. Bring the eLCDIF out of soft reset and clock gate.
5. Reset the LCD controller by setting LCDIF\_CTRL1\_RESET bit appropriately, being careful to observe the reset requirements of the controller.
6. Set the READ\_WRITEB bit in LCDIF\_CTRL register to 1.
7. Set the LCDIF\_MASTER bit in LCDIF\_CTRL register to 0. Bus master mode is not supported for reading data from the display.

8. Also, set the `DATA_SHIFT_DIR` and `SHIFT_NUM_BITS` if it is required to shift the data left or right before it is output.
9. Indicate if the read data needs to be color-space-converted and stored in a different RGB format by setting the `READ_MODE_OUTPUT_IN_RGB_FORMAT` field accordingly.
10. Set the `WORD_LENGTH` field appropriately: 0 = 16-bit input, 1 = 8-bit input, 2 = 18-bit input, 3 = 24-bit input if `READ_MODE_OUTPUT_IN_RGB_FORMAT` is required. Also, select the correct 16/18/24 bit data format with the corresponding fields in `LCDIF_CTRL` register.
11. Set the `READ_MODE_NUM_PACKED_SUBWORDS` field in `LCDIF_CTRL2` according to the number of subwords per word required to be packed.
12. Set the `READ_PACK_DIR` to 1 if it is required to store the data in big-endian format.
13. Set the `LCD_DATABUS_WIDTH` appropriately: 0 = 16-bit output, 1 = 8-bit output, 2 = 18-bit output, 3 = 24-bit output.
14. Enable the necessary IRQs.

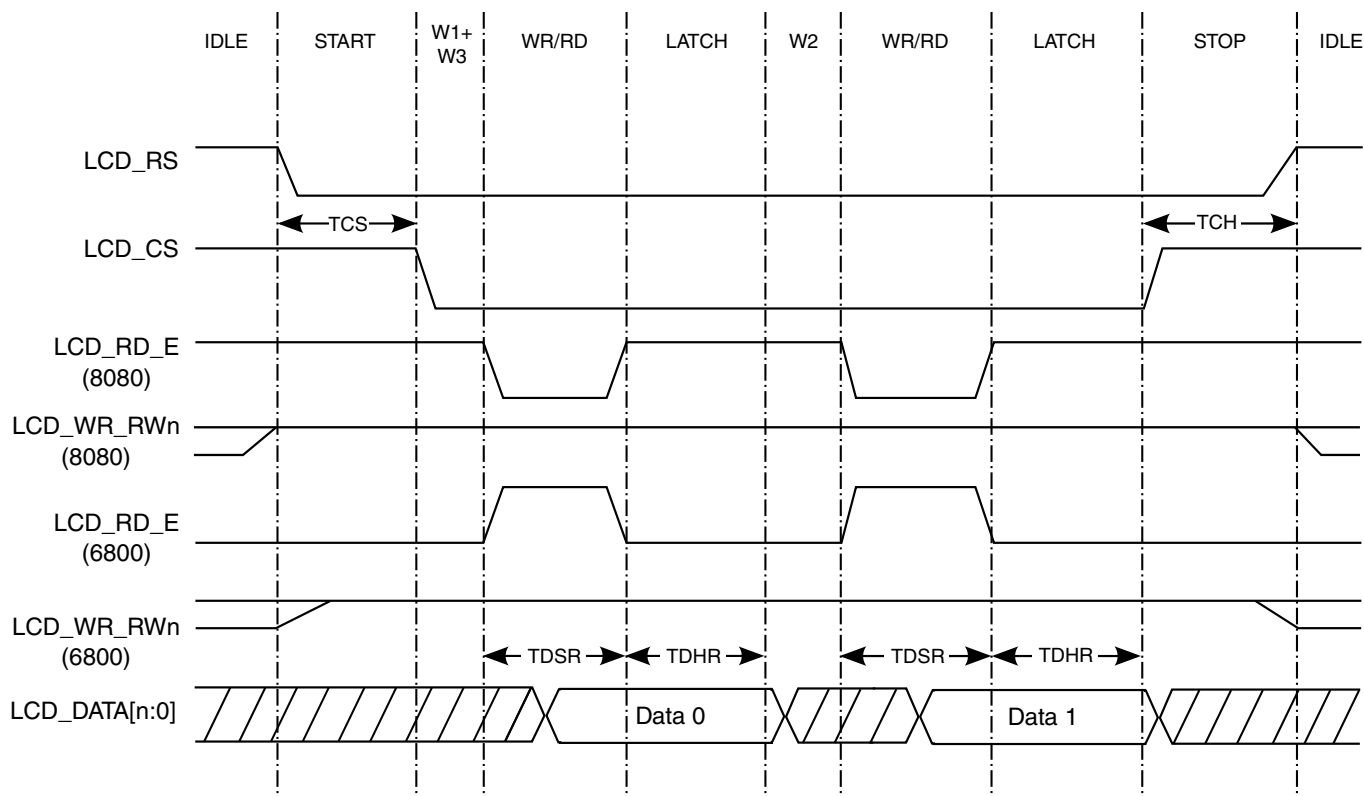

### **13.2.4.6 MPU Interface**

The MPU interface is used to transfer data and commands between the SoC via the eLCDIF and the external display at modest data rates.

Bus master or PIO transactions using the `LCDIF_DATA` register can be used for MPU mode write operations. For MPU mode read operations, only PIO can be used. eLCDIF can support the 6800 as well as the 8080 MPU protocol. If `DOTCLK_MODE`, `DVI_MODE` and `VSYNC_MODE` bits in `LCDIF_CTRL` registers are 0, it implies that the block is in MPU interface mode of operation. The LCDIF MPU mode has four basic timing parameters: Setup and Hold for the Command/Data register selection (TCS, TCH) and Setup and Hold for the Data bus (TDS, TDH). These parameters are expressed in `DISPLAY_CLK` cycles. The `LCD_WR` signal is used as the write strobe while `LCD_RS` signal is typically used to switch between command and data modes.

**Figure 13-13. Timing in write mode of 6800 and 8080 protocols**

**Figure 13-14. Read timing interface in 6800 and 8080 protocols**

The eLCDIF has flexible pin and strobe timings which enable it to optimally support a wide range of LCDs. The minimum cycle time is two DISPLAY\_CLK cycles (TDS=TDH=1). For example, this results in a maximum LCD data rate of 12 MB/s when DISPLAY\_CLK is 24 MHz. TDS and TDH are 8-bit values, so the minimum eLCDIF period is 510 DISPLAY\_CLK cycles (47 KHz with a 24 MHz DISPLAY\_CLK). The timings are not automatically adjusted if the DISPLAY\_CLK frequency changes, so it may be necessary to adjust the timings if DISPLAY\_CLK changes.

In the MPU interface mode, the LCDIF\_CTRL\_ BYPASS\_COUNT bit must be 0. The RUN bit is cleared automatically once the eLCDIF has received/transmitted all the data as per the LCDIF\_TRANSFER\_COUNT register and has completed the transfer to the panel. The current transfer can be cancelled/aborted if the RUN bit is manually made 0.

### 13.2.4.6.1 Code Example to Initialize the eLCDIF in MPU Write Mode

```
// Note: Common initialization steps in Initializing the eLCDIF must also be
// executed along with the following code
BF_CS1(LCDIF_CTRL, DATA_SELECT, 1); // 0 if sending command, 1 if sending data. Note that the
// idle state for LCD_RS signal is high, regardless of the
// programming of the DATA_SELECT register.
BF_CS1 (LCDIF_CTRL, MODE86, 8080_MODE);
BF_CS1 (LCDIF_CTRL, READ_WRITEB, 0);
BF_CS1 (LCDIF_CTRL, BYPASS_COUNT, 0); //Must be 0 in MPU mode
BF_CS1 (LCDIF_CTRL1, BUSY_ENABLE, 1); //Only if LCD controller implements a busy line
BF_CS4 (LCDIF_TIMING, CMD_HOLD, 2, CMD_SETUP, 2, DATA_HOLD, 2, DATA_SETUP, 2); //Values
based
// on DISPLAY_CLK frequency and timing requirements of
controller.
// Note that these register must be non-zero for correct
operation.
BF_CS2 (LCDIF_TRANSFER_COUNT, H_COUNT, 320, V_COUNT, 240); //For a 320 RGB x 240 display
BF_CS1 (LCDIF_CTRL, RUN, 1);
```

The eLCDIF is now ready to receive data via bus master PIO write transactions using the LCDIF\_DATA register. Note that when using the PIO write operations to the LCDIF\_DATA register, the software will need to poll the FIFO STATUS bits to ensure that it does not overflow the eLCDIF data buffers. When eLCDIF is done transmitting H\_COUNT x V\_COUNT pixels, it will stop, turn off the RUN bit and assert the cur\_frame\_done interrupt.

### 13.2.4.7 VSYNC Interface

The VSYNC interface uses the same protocol as the MPU interface, with an additional signal VSYNC at the frame rate of the display, as shown in the figure given in MPU Interface section.

It is used in the moving picture display mode where data has to be written to the internal LCD buffer at a speed higher than the display rate and displayed in synchronization with the VSYNC signal. This mode is selected by setting the VSYNC\_MODE bit in

LCDIF\_CTRL register. The VSYNC signal is programmable for period, polarity and direction. Many other programmable parameters are shared with the MPU interface. The VSYNC\_OEB bit in LCDIF\_VDCTRL0 register indicates whether the display controller will send the VSYNC signal, or whether it should be generated by eLCDIF. The timing of the VSYNC signal is based on the DISPLAY\_CLK (make sure VSYNC\_PULSE\_WIDTH\_UNIT = VSYNC\_PERIOD\_UNIT = 0 and VSYNC\_ONLY = 1) and it is determined by the VSYNC\_PERIOD, VSYNC\_PULSE\_WIDTH and VSYNC\_POL fields in LCDIF\_VDCTRL0-4 registers. The SYNC\_SIGNALS\_ON bit in LCDIF\_VDCTRL4 register must be set if the target requires the VSYNC signal to be generated by eLCDIF. If the WAIT\_FOR\_VSYNC\_EDGE bit in LCDIF\_CTRL register is set, it indicates that the hardware should wait until it sees the leading VSYNC edge before starting the data transfer. The VERTICAL\_WAIT\_CNT indicates the number of DISPLAY\_CLK cycles from the leading VSYNC edge after which data transfer will be started on the interface.

In the VSYNC interface mode, the LCDIF\_CTRL\_BYPASS\_COUNT bit must be 0. The RUN bit is cleared automatically once the eLCDIF has received/transmitted all the data as per the LCDIF\_TRANSFER\_COUNT register and has completed the transfer to the panel. The current transfer can be cancelled/aborted if the RUN bit is manually made 0.

### 13.2.4.7.1 Code Example to Initialize eLCDIF in VSYNC Mode

```
// Note: Common initialization steps in Initializing the eLCDIF must also be
// executed along with the following code
BF_CS1 (LCDIF_CTRL, DATA_SELECT, 1); // 0 if sending command, 1 if sending data. Note that
//the idle state for LCD_RS signal is high, regardless of the programming of the DATA_SELECT
//register.

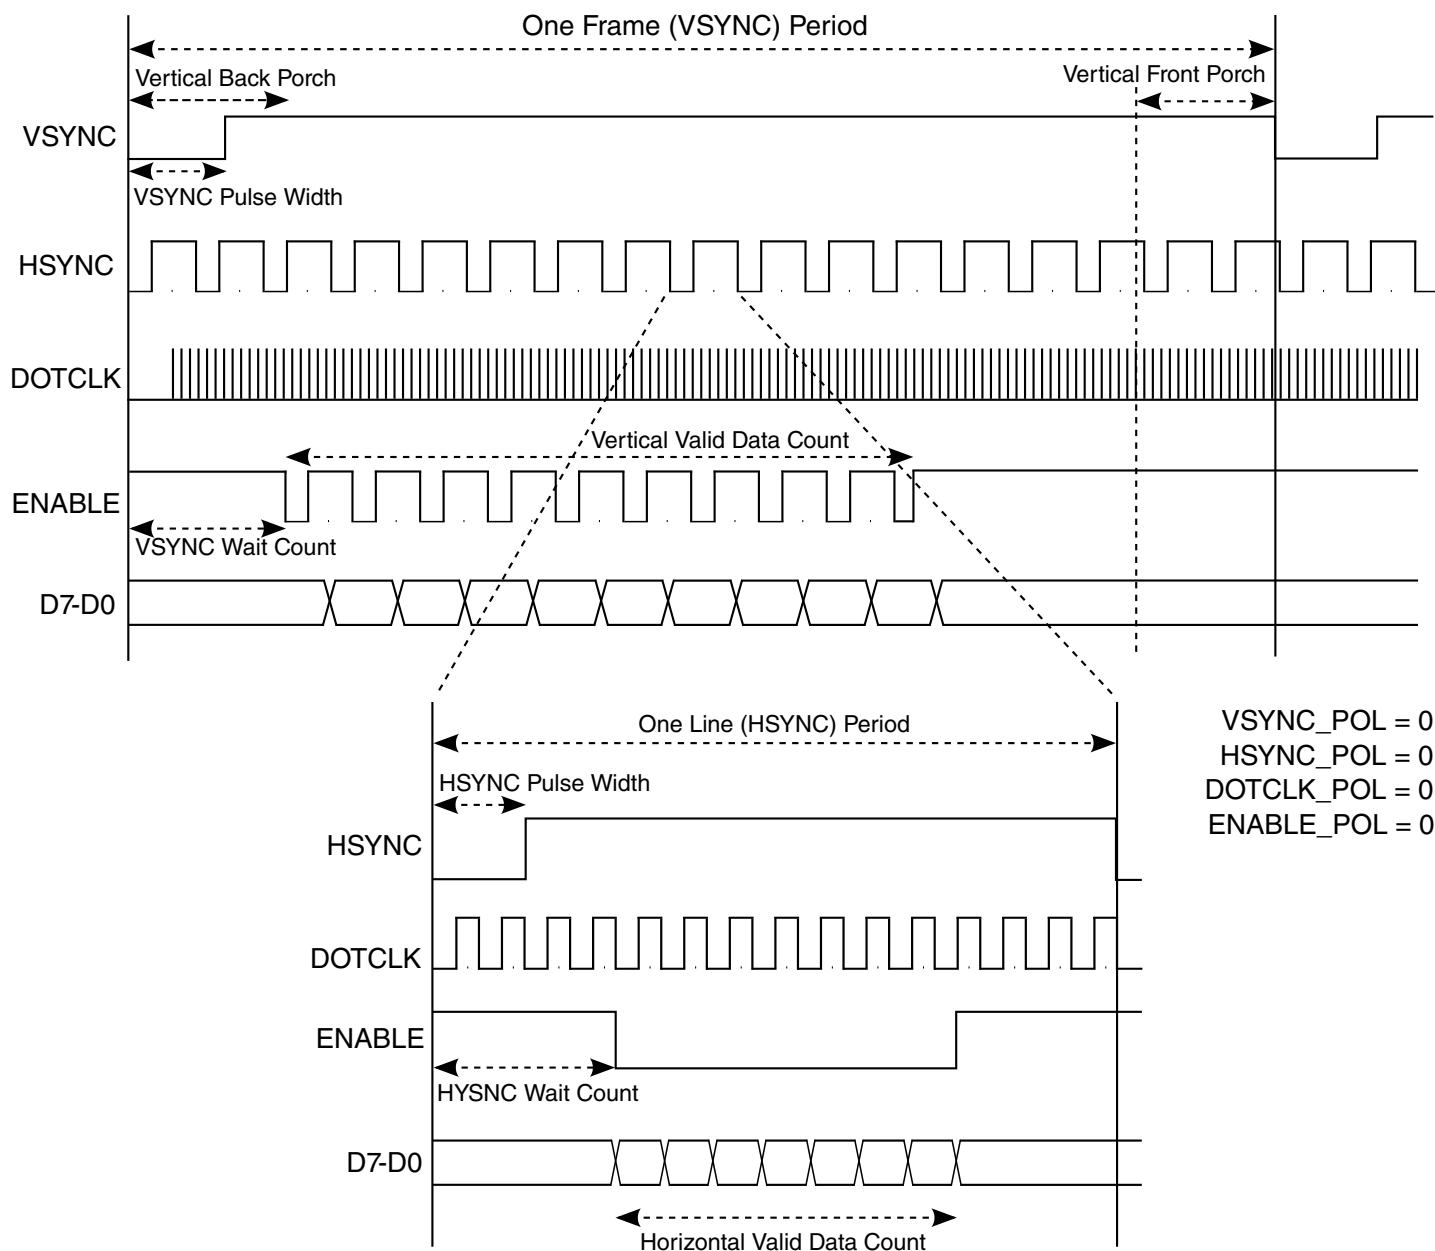

BF_CS1 (LCDIF_CTRL, MODE86, 8080_MODE);
BF_CS1 (LCDIF_CTRL, BYPASS_COUNT, 0); //Must be 0 in MPU mode
BF_CS1 (LCDIF_CTRL1, BUSY_ENABLE, 0);
BF_CS4 (LCDIF_TIMING, CMD_HOLD, 2, CMD_SETUP, 2, DATA_HOLD, 2, DATA_SETUP, 2); //Values
//based on DISPLAY_CLK frequency and timing requirements of controller. Note that these
//register must be non-zero for the MPU and VSYNC modes.
BF_CS2 (LCDIF_TRANSFER_COUNT, H_COUNT, 320, V_COUNT, 240); //For a 320 RGB x 240 display
//The following section indicates setting up the VSYNC signal timing when VSYNC is an output
BF_CS1 (LCDIF_VDCTRL0, VSYNC_OEB, 0); //Making VSYNC signal an output
BF_CS1 (LCDIF_VDCTRL4, VSYNC_ONLY, 1); //Only need to generate VSYNC signal
BF_CS1 (VDCTRL0, VSYNC_POL, 0); //Setting the polarity of VSYNC signal to be low during
//VSYNC_PULSE_WIDTH time
BF_CS2 (LCDIF_VDCTRL0, VSYNC_PERIOD_UNIT, 0, VSYNC_PULSE_WIDTH_UNIT, 0);
BF_CS2 (LCDIF_VDCTRL1, VSYNC_PERIOD, 400000, VSYNC_PULSE_WIDTH, 100); //Frame display rate in
//terms of number of DISPLAY_CLKs.
BF_CS2 (LCDIF_VDCTRL2, HSYNC_PULSE_WIDTH, 0, HSYNC_PERIOD, 0);
BF_CS1 (LCDIF_VDCTRL3, VERTICAL_WAIT_CNT, 50);
BF_CS1 (LCDIF_VDCTRL4, SYNC_SIGNALS_ON, 1);
BF_CS2 (LCDIF_CTRL, VSYNC_MODE, 1, WAIT_FOR_VSYNC_EDGE, 1); //set WAIT_FOR_VSYNC_EDGE if
//software wishes to transfer the next frame after the VSYNC edge occurs.
BF_CS1 (LCDIF_CTRL, RUN, 1);
```

The eLCDIF is now ready to receive data via bus master requests or PIO writes to the LCDIF\_DATA register. When eLCDIF is done transmitting  $H\_COUNT \times V\_COUNT$  pixels, it will stop, turn off the RUN bit and assert the cur\_frame\_done interrupt.

### 13.2.4.8 DOTCLK Interface

The DOTCLK interface is another mode used in moving picture displays.

It includes the VSYNC, HSYNC, DOTCLK and (optional) ENABLE signals. The interface is popularly called the RGB interface if the ENABLE signal is present.

**Figure 13-15. DOTCLK protocol with programmable parameters**

The DOTCLK mode writes data at high speed to the LCD, and the display operation is synchronized with the VSYNC, HSYNC, ENABLE and DOTCLK signals. The polarities, periods and pulse-widths of the sync signals are programmable using the LCDIF\_VDCTRL0-4 registers. The units for the VSYNC signal must be number of horizontal lines and can be selected using the VSYNC\_PULSE\_WIDTH\_UNIT and VSYNC\_PERIOD\_UNIT bit fields. The VERTICAL\_WAIT\_CNT is by default given the same unit as the VSYNC\_PERIOD. The DISPLAY\_CLK frequency is managed by the CCM.

In DOTCLK mode, LCDIF\_CTRL\_BYPASS\_COUNT bit must be set to 1. To end the current transfer, the software should make the DOTCLK\_MODE bit 0, so that all data that is currently in the LCDIF LFIFO and TXFIFO is transmitted. Once that transfer is complete, the block will automatically clear the RUN bit and issue the cur\_frame\_done interrupt.

### 13.2.4.8.1 Code Example

The following code shows an example for programming a 320x240 display. Note that setting up the display must be done through the MPU mode or via SPI.

```
// Note: Common initialization steps in Initializing the eLCDIF must also be
// executed along with the following code
BF_CS1 (LCDIF_CTRL, DOTCLK_MODE, 1);
BF_CS1 (LCDIF_CTRL, BYPASS_COUNT, 1); //Always for DOTCLK mode
BF_CS1 (LCDIF_VDCTRL0, VSYNC_OEB, 0); //Vsync is always an output in the DOTCLK mode
BF_CS4 (LCDIF_VDCTRL0, VSYNC_POL, 0, HSYNC_POL, 0, DOTCLK_POL, 0, ENABLE_POL, 0);
BF_CS1 (LCDIF_VDCTRL0, ENABLE_PRESENT, 1);
BF_CS2 (LCDIF_VDCTRL0, VSYNC_PERIOD_UNIT, 1, VSYNC_PULSE_WIDTH_UNIT, 1);
BF_CS1 (LCDIF_VDCTRL0, VSYNC_PULSE_WIDTH, 2);
BF_CS1 (LCDIF_VDCTRL1, VSYNC_PERIOD, 280);
BF_CS2 (LCDIF_VDCTRL2, HSYNC_PULSE_WIDTH, 10, HSYNC_PERIOD, 360); //Assuming
// LCD_DATABUS_WIDTH is 24bit
BF_CS2 (LCDIF_VDCTRL3, VSYNC_ONLY, 0);
BF_CS2 (LCDIF_VDCTRL3, HORIZONTAL_WAIT_CNT, 20, VERTICAL_WAIT_CNT, 20);
BF_CS1 (LCDIF_VDCTRL4, DOTCLK_H_VALID_DATA_CNT, 320); //Note that DOTCLK_V_VALID_DATA_CNT is
//implicitly assumed to be HW_LCDIF_TRANSFER_COUNT_V_COUNT
BF_CS1 (LCDIF_VDCTRL4, SYNC_SIGNALS_ON, 1);
BF_CS1 (LCDIF_CTRL, RUN, 1);
```

To stop the transfer completely, the ideal way is to make DOTCLK\_MODE = 0. In that case, the block will transmit the contents in the FIFO and reset the RUN bit.

### 13.2.4.9 CSI HANDSHAKE INTERFACE

The LCDIF and CSI support a pipeline mode to use double buffers inside OGRAM for the video pass through from CSI to LCDIF, the pipeline buffer size can be 8 line or 16 line as configurable. The pipeline will be handle by hardware handshake signals between CSI and LCDIF. The LCDIF will have the capability to synchronize display with CSI based on the VSYNC signal from CSI. When LCDIF is enabled to start display, it can optionally wait for the VSYNC edge from CSI before it starts the display for next frame, The delay from VSYNC input to the start of next frame is programmable by LCDIF\_SYNC\_DELAY register.

**Figure 13-16. CSI HandShake Interface**

When this mode is enabled, the hardware handshake protocol will process. At the start of CSI with camera input, the CSI will put the input data to one frame buffer. When the frame buffer is ready for LCDIF display, CSI will assert `csi_ready` signal to indicate LCDIF to read the buffer and LCDIF will display data in this buffer. When one frame buffer reading finished, LCDIF will set the `lcdif_done` signal to indicate CSI this buffer has been displayed and can be written again. With this double buffer handshake mode, the LCDIF can display the video input within very short delay and minimize DRAM bandwidth.

### 13.2.4.10 Alpha Blending Interface

The LCDIF has the capability to add an extra overlay on the normal display buffer. LCDIF can fetch data from two buffers and combine them before display, one buffer data can have the alpha value with the RGB pixels. With `LCDIF_AS_CTRL[AS_ENABLE]` is set, the LCDIF will start fetching alpha surface buffer data in bus master mode and combine it with another buffer.

The `LCDIF_AS_CTRL[ALPHA_CTRL]` bits determine how the alpha value is constructed for the alpha surface and alpha blending process is as same as in PXP block, for the alpha blend and color key process refer to the PXP block descriptions.

### 13.2.4.11 ITU-R BT.656 Digital Video Interface (DVI)

ITU-R BT.656 Digital Video Interface shown below transmits 4:2:2 YCbCr digital component video to a digital video encoder that can translate it into 525/60 or 625/50 analog TV signal.

Unique timing codes (timing reference signals) are embedded within the video stream to indicate the different timing events that would have been otherwise indicated by VSYNC, HSYNC and BLANK signals. The hardware supports 8-bit data transfers; the pins are shared with the lower 8 bits of LCD data bus. The LCD\_RS pin is shared with the clock signal of the interface (called CCIRCLK here for uniqueness). CCIRCLK also can be obtained on the LCD\_DOTCK pin. The mode shares the write FIFO with the LCD interface and the associated pipeline. The programmable parameters in registers LCDIF\_DVICTRL0-3 allow setting the total number of horizontal lines per frame, vertical and horizontal blanking interval, odd and even field start and end positions, and so on. In short, these parameters are provided to ensure that the hardware has enough flexibility to generate the right 525/60 or 625/50 data streams. Most of the initialization steps in [Initializing the eLCDIF](#) such as data shifting, swizzle, and so on, are applicable to DVI mode also. The register descriptions in the programmable registers section at the end of this chapter include example code for programming the DVICTRL0-3 registers.

In DVI mode, LCDIF\_CTRL\_BYPASS\_COUNT bit must be set to 1. To end the current transfer, the software should make the DVI\_MODE bit the value 0, so that all data that is currently in the LCDIF LFIFO and TXFIFO is transmitted. Once that transfer is complete, the block will automatically clear the RUN bit and assert the cur\_frame\_done interrupt.

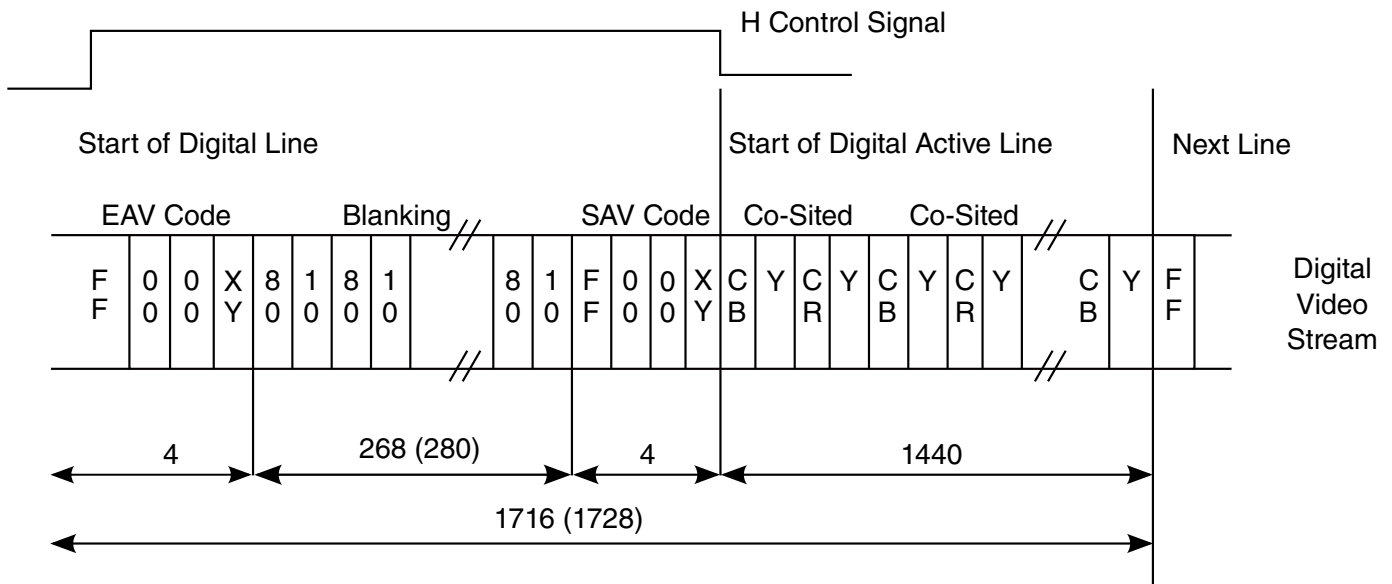

Figure 13-17. Digital Video Interface

### 13.2.4.12 eLCDIF Pin Usage by Interface Mode

Table 13-3 and Table 13-4 indicates how the eLCDIF level interface pins are used based on the desired mode of operation. The chip level I/Os should also be configured to be consistent with the desired eLCDIF operating mode.

The VSYNC signal has been mapped onto two pins, LCD\_BUSY and LCD\_VSYNC. The pin multiplexing can be programmed to select either of those pins to function as VSYN.

#### NOTE

There is an option to internally mux the HSYNC, DOTCLK and ENABLE signals in the DOTCLK mode by setting the MUX\_SYNC\_SIGNALS bit in the VDCTRL0 register. There is also an option to internally mux the LCD\_WR\_RWn and LCD\_RD\_E pins in the CTRL1 register for backward compatibility.

### 13.2.5 Behavior During Reset

BUS\_CLK and DISPLAY\_CLK must be running before making any changes to SFTRST or CLKGATE bits.

A soft reset (SFTRST) can take multiple clock periods to complete, so do not set CLKGATE when setting SFTRST.

The reset process gates the clocks automatically.

### 13.2.6.1 eLCDIF General Control Register (LCDIFx\_RLn)

The LCD Interface Control Register provides overall control of the eLCDIF block. The eLCDIF Control Register provides a variety of control functions to the programmer. These functions allow the interface to be very flexible to work with a variety of LCD controllers, and to minimize overhead and increase performance of LCD programming. The register has been organized such that switching between the different LCD modes can be done with minimum PIO writes.

Address: Base address + 0h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

LCDIFx\_RLn field descriptions

Field	Description
31 SFTRST	This bit must be set to zero to enable normal operation of the eLCDIF. When set to one, it forces a block level reset.
30 CLKGATE	This bit must be set to zero for normal operation. When set to one it gates off the clocks to the block.
29 YCBCR422_INPUT	Zero implies input data is in RGB color space. One implies input data is in YCbCr 4:2:2 format, such that YCbYCr are packed in a 32-bit word. It also means that there are 2 pixels in 4 bytes. If this bit is set, software should program the H_COUNT field in the TRANSFER_COUNT register to the total number of pixels that will have to be fetched by the eLCDIF block per line and the BYTE_PACKING_FORMAT should be 0xF. The WORD_LENGTH does not matter in this case.

Table continues on the next page...

LCDIFx\_RL<sub>n</sub> field descriptions (continued)

Field	Description
28 READ_WRITEB	By default, eLCDIF is in the write mode. Setting this bit to 1 will make the hardware go into 6800/8080 MPU read mode. The LCDIF_MASTER bit must be 0, since bus master mode can only be used for writing the display.
27 WAIT_FOR_VSYNC_EDGE	Setting this bit to 1 will make the hardware wait for the triggering VSYNC edge before starting write transfers to the LCD. Used only in the VSYNC mode of operation.
26 DATA_SHIFT_DIR	Use this bit to determine the direction of shift of transmit data. In the DVI mode, it works only on the active data, not on the timing codes and ancillary data. 0x0 <b>TXDATA_SHIFT_LEFT</b> — Data to be transmitted is shifted LEFT by SHIFT_NUM_BITS bits. 0x1 <b>TXDATA_SHIFT_RIGHT</b> — Data to be transmitted is shifted RIGHT by SHIFT_NUM_BITS bits.
25–21 SHIFT_NUM_BITS	The data to be transmitted is shifted left or right by this number of bits.
20 DVI_MODE	Set this bit to 1 to get into the ITU-R BT.656 digital video interface mode. Toggle this bit from 1 to 0 to make the hardware go out of DVI mode after completing all data transfer and after the RUN bit has been deasserted.
19 BYPASS_COUNT	When this bit is 0, it means that eLCDIF will stop the block operation and turn off the RUN bit after the amount of data indicated by the LCDIF_TRANSFER_COUNT register has been transferred out. When this bit is set to 1, the block will continue normal operation indefinitely until it is told to stop. This bit must be 0 in MPU and VSYNC modes, and must be 1 in DOTCLK and DVI modes of operation.
18 VSYNC_MODE	Setting this bit to 1 will make the eLCDIF hardware go into VSYNC mode. WAIT_FOR_VSYNC_EDGE can be used only if this bit is set. If VSYNC signal is required to be an output from the block, SYNC_SIGNALS_ON bit in LCDIF_VDCTRL4 register must be set.
17 DOTCLK_MODE	Set this bit to 1 to make the hardware go into the DOTCLK mode, i.e. VSYNC/HSYNC/DOTCLK/ENABLE interface mode. ENABLE is optional, selected by the ENABLE_PRESENT bit. Toggle this bit from 1 to 0 to make the hardware go out of DOTCLK mode after completing all data transfer and deasserting the RUN bit.
16 DATA_SELECT	Command Mode polarity bit. This bit should only be changed when RUN is 0. 0x0 <b>CMD_MODE</b> — Command Mode. DC <sub>n</sub> signal is Low. 0x1 <b>DATA_MODE</b> — Data Mode. DC <sub>n</sub> signal is High.
15–14 INPUT_DATA_SWIZZLE	This field specifies how to swap the bytes fetched by the bus master interface. The swizzle function is independent of the WORD_LENGTH bit. The supported swizzle configurations are: 0x0 <b>NO_SWAP</b> — No byte swapping.(Little endian) 0x0 <b>LITTLE_ENDIAN</b> — Little Endian byte ordering (same as NO_SWAP). 0x1 <b>BIG_ENDIAN_SWAP</b> — Big Endian swap (swap bytes 0,3 and 1,2). 0x1 <b>SWAP_ALL_BYTES</b> — Swizzle all bytes, swap bytes 0,3 and 1,2 (aka Big Endian). 0x2 <b>HWD_SWAP</b> — Swap half-words. 0x3 <b>HWD_BYTE_SWAP</b> — Swap bytes within each half-word.
13–12 CSC_DATA_SWIZZLE	This field specifies how to swap the bytes after the data has been converted into an internal representation of 24 bits per pixel and before it is transmitted over the LCD interface bus. The data is always transmitted with the least significant byte/hword (half word) first after the swizzle takes place. So, INPUT_DATA_SWIZZLE takes place first on the incoming data, and then CSC_DATA_SWIZZLE is applied. The swizzle function is independent of the WORD_LENGTH or the LCD_DATABUS_WIDTH fields. If RGB_TO_YCRCB422_CSC bit is set, the swizzle occurs on the Y, Cb, Cr values. The supported swizzle configurations are: 0x0 <b>NO_SWAP</b> — No byte swapping.(Little endian)

*Table continues on the next page...*

LCDIFx\_RL<sub>n</sub> field descriptions (continued)

Field	Description
	0x0 <b>LITTLE_ENDIAN</b> — Little Endian byte ordering (same as NO_SWAP). 0x1 <b>BIG_ENDIAN_SWAP</b> — Big Endian swap (swap bytes 0,3 and 1,2). 0x1 <b>SWAP_ALL_BYTES</b> — Swizzle all bytes, swap bytes 0,3 and 1,2 (aka Big Endian). 0x2 <b>HWD_SWAP</b> — Swap half-words. 0x3 <b>HWD_BYTE_SWAP</b> — Swap bytes within each half-word.
11–10 LCD_DATABUS_ WIDTH	LCD Data bus transfer width. 0x0 <b>16_BIT</b> — 16-bit data bus mode. 0x1 <b>8_BIT</b> — 8-bit data bus mode. 0x2 <b>18_BIT</b> — 18-bit data bus mode. 0x3 <b>24_BIT</b> — 24-bit data bus mode.
9–8 WORD_LENGTH	Input data format. 0x0 <b>16_BIT</b> — Input data is 16 bits per pixel. 0x1 <b>8_BIT</b> — Input data is 8 bits wide. 0x2 <b>18_BIT</b> — Input data is 18 bits per pixel. 0x3 <b>24_BIT</b> — Input data is 24 bits per pixel.
7 RGB_TO_ YCBCR422_CSC	Set this bit to 1 to enable conversion from RGB to YCbCr colorspace. See the LCDIF_CSC_ registers for further details.
6 ENABLE_PXP_ HANDSHAKE	If this bit is set and LCDIF_MASTER bit is set, the eLCDIF will act as bus master and the handshake mechanism between eLCDIF and PXP will be turned on. If LCDIF_MASTER bit is not set, this bit becomes a don't care.
5 MASTER	Set this bit to make the eLCDIF act as a bus master. If this bit is reset, the eLCDIF will support or PIO mode.
4 RSRVD0	This field is reserved. Reserved bits. Write as 0.
3 DATA_ FORMAT_16_ BIT	When this bit is 1 and WORD_LENGTH = 0, it implies that the 16-bit data is in ARGB555 format. When this bit is 0 and WORD_LENGTH = 0, it implies that the 16-bit data is in RGB565 format. When WORD_LENGTH is not 0, this bit does not care.
2 DATA_ FORMAT_18_ BIT	Used only when WORD_LENGTH = 2, i.e. 18-bit. 0x0 <b>LOWER_18_BITS_VALID</b> — Data input to the block is in 18 bpp format, such that lower 18 bits contain RGB 666 and upper 14 bits do not contain any useful data. 0x1 <b>UPPER_18_BITS_VALID</b> — Data input to the block is in 18 bpp format, such that upper 18 bits contain RGB 666 and lower 14 bits do not contain any useful data.
1 DATA_ FORMAT_24_ BIT	Used only when WORD_LENGTH = 3, i.e. 24-bit. Note that this applies to both packed and unpacked 24-bit data. 0x0 <b>ALL_24_BITS_VALID</b> — Data input to the block is in 24 bpp format, such that all RGB 888 data is contained in 24 bits. 0x1 <b>DROP_UPPER_2_BITS_PER_BYTE</b> — Data input to the block is actually RGB 18 bpp, but there is 1 color per byte, hence the upper 2 bits in each byte do not contain any useful data, and should be dropped.
0 RUN	When this bit is set by software, the eLCDIF will begin transferring data between the SoC and the display. This bit must remain set until the operation is complete.

### 13.2.6.2 eLCDIF General Control1 Register (LCDIFx\_CTRL1n)

The eLCDIF Control Register provides overall control of the eLCDIF block.

The eLCDIF Control1 Register provides additional programming to the eLCDIF. It implements some bits which are unlikely to change often in a particular application. It also carries interrupt-related bits which are common across more than one mode of operation.

Address: Base address + 10h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved				COMBINE_MPU_WR_STRB	BM_ERROR_IRQ_EN	BM_ERROR_IRQ	RECOVER_ON_UNDERFLOW	INTERLACE_FIELDS	START_INTERLACE_FROM_SECOND_FIELD	FIFO_CLEAR	IRQ_ON_ALTERNATE_FIELDS	BYTE_PACKING_FORMAT

**LCDIFx\_CTRL1n field descriptions**

Field	Description
31–28 RSRVD1	This field is reserved. Reserved bits. Write as 0.
27 COMBINE_MPU_WR_STRB	If this bit is not set, the write strobe will be driven on LCD_WR_RWn pin in the 8080 mode and on the LCD_RD_E pin in the 6800 mode. If it is set, the write strobe of both the 6800 and 8080 modes will be driven only on the LCD_WR_RWn pin. Note that this does not work for read strobe.
26 BM_ERROR_IRQ_EN	This bit is set to enable bus master error interrupt in the eLCDIF master mode.
25 BM_ERROR_IRQ	This bit is set to indicate that an interrupt is requested by the eLCDIF block. This bit is cleared by software by writing a one to its SCT clear address. This bit will be set when the eLCDIF is in master mode and an error response was returned by the slave.

*Table continues on the next page...*

## LCDIFx\_CTRL1n field descriptions (continued)

Field	Description
	0x0 <b>NO_REQUEST</b> — No Interrupt Request Pending. 0x1 <b>REQUEST</b> — Interrupt Request Pending.
24 RECOVER_ON_ UNDERFLOW	Set this bit to enable the eLCDIF block to recover in the next field/frame if there was an underflow in the current field/frame.
23 INTERLACE_ FIELDS	Set this bit if it is required that the eLCDIF block fetches odd lines in one field and even lines in the other field. It will work only in LCDIF_MASTER is set to 1.
22 START_ INTERLACE_ FROM_ SECOND_FIELD	The default is to grab the odd lines first and then the even lines. Set this bit if it is required to grab the even lines first and then the odd lines. (Line numbers start from 1, so odd lines are 1,3,5,etc. and even lines are 2,4,6, etc.)
21 FIFO_CLEAR	Set this bit to clear all the data in the latency FIFO (LFIFO), TXFIFO and the RXFIFO.
20 IRQ_ON_ ALTERNATE_ FIELDS	If this bit is set, the eLCDIF block will assert the cur_frame_done interrupt only on alternate fields, otherwise it will issue the interrupt on both odd and even field. This bit is mostly relevant if INTERLACE_FIELDS is set. This feature is only available in DOTCLK and DVI modes.
19–16 BYTE_ PACKING_ FORMAT	This bitfield is used to show which data bytes in a 32-bit word are valid. Default value 0xf indicates that all bytes are valid. For 8-bit transfers, any combination in this bitfield will mean valid data is present in the corresponding bytes. In the 16-bit mode, a 16-bit half-word is valid only if adjacent bits [1:0] or [3:2] or both are 1. A value of 0x0 will mean that none of the bytes are valid and should not be used. For example, set the bit field value to 0x7 if the display data is arranged in the 24-bit unpacked format (A-R-G-B where A value does not have to be transmitted). When input data is in YCbCr 4:2:2 format (YCBCR422_INPUT is 1), H_COUNT should be the number of pixels that should be fetched by the block and the BYTE_PACKING_FORMAT should be 0xF. (Note - YCBCR422_INPUT = 1 implies 2 pixels per 32 bits).
15 OVERFLOW_ IRQ_EN	This bit is set to enable an overflow interrupt in the TXFIFO in the write mode.
14 UNDERFLOW_ IRQ_EN	This bit is set to enable an underflow interrupt in the TXFIFO in the write mode.
13 CUR_FRAME_ DONE_IRQ_EN	This bit is set to 1 enable an interrupt every time the hardware enters in the vertical blanking state.
12 VSYNC_EDGE_ IRQ_EN	This bit is set to enable an interrupt every time the hardware encounters the leading VSYNC edge in the VSYNC and DOTCLK modes, or the beginning of every field in DVI mode.
11 OVERFLOW_ IRQ	This bit is set to indicate that an interrupt is requested by the eLCDIF block. This bit is cleared by software by writing a one to its SCT clear address. A latency FIFO (LFIFO) overflow in the write mode (MPU/VSYNC/DOTCLK/DVI mode) was detected, data samples have been lost.  0x0 <b>NO_REQUEST</b> — No Interrupt Request Pending. 0x1 <b>REQUEST</b> — Interrupt Request Pending.
10 UNDERFLOW_ IRQ	This bit is set to indicate that an interrupt is requested by the eLCDIF block. This bit is cleared by software by writing a one to its SCT clear address. A TXFIFO underflow in the write mode (MPU/VSYNC/DOTCLK/DVI mode) was detected. Could produce an error in the DOTCLK / DVI modes.

*Table continues on the next page...*

## LCDIFx\_CTRL1n field descriptions (continued)

Field	Description
	0x0 <b>NO_REQUEST</b> — No Interrupt Request Pending. 0x1 <b>REQUEST</b> — Interrupt Request Pending.
9 CUR_FRAME_ DONE_IRQ	This bit is set to indicate that an interrupt is requested by the eLCDIF block. This bit is cleared by software by writing a one to its SCT clear address. It indicates that the hardware has completed transmitting the current frame and is in the vertical blanking period in the DOTCLK/DVI modes. In the MPU and VSYNC modes, this IRQ is asserted at the end of the data transfer indicated by LCDIF_TRANSFER_COUNT register.  0x0 <b>NO_REQUEST</b> — No Interrupt Request Pending. 0x1 <b>REQUEST</b> — Interrupt Request Pending.
8 VSYNC_EDGE_ IRQ	This bit is set to indicate that an interrupt is requested by the eLCDIF block. This bit is cleared by software by writing a one to its SCT clear address. It is set whenever the leading VSYNC edge is detected in the VSYNC and DOTCLK modes. In the DVI mode, it is asserted every time the block enters a new field.  0x0 <b>NO_REQUEST</b> — No Interrupt Request Pending. 0x1 <b>REQUEST</b> — Interrupt Request Pending.
7–3 RSRVD0	This field is reserved. Reserved bits. Write as 0.
2 BUSY_ENABLE	This bit enables the use of the interface's busy signal input. This should be enabled for LCD controllers that implement a busy line (to stall the eLCDIF from sending more data until ready). Otherwise this bit should be cleared.  0x0 <b>BUSY_DISABLED</b> — The busy signal from the LCD controller will be ignored. 0x1 <b>BUSY_ENABLED</b> — Enable the use of the busy signal from the LCD controller.
1 MODE86	This bit is used to select between the 8080 and 6800 series of microprocessor modes. This bit should only be changed when RUN is 0.  0x0 <b>8080_MODE</b> — Pins LCD_WR_RWn and LCD_RD_E function as active low WR and active low RD signals respectively. 0x1 <b>6800_MODE</b> — Pins LCD_WR_RWn and LCD_RD_E function as Read/Write and active high Enable signals respectively.
0 RESET	Reset bit for the external LCD controller. This bit can be changed at any time. It CANNOT be reset by SFTRST.  0x0 <b>LCDRESET_LOW</b> — LCD_RESET output signal is low. 0x1 <b>LCDRESET_HIGH</b> — LCD_RESET output signal is high.

### 13.2.6.3 eLCDIF General Control2 Register (LCDIFx\_CTRL2n)

The eLCDIF Control Register provides overall control of the eLCDIF block.

The eLCDIF Control2 Register provides additional programming to the eLCDIF. It implements some bits which are unlikely to change often in a particular application.

## Enhanced LCD Interface (eLCDIF)

Address: Base address + 20h offset + (4d × i), where i=0d to 3d

### LCDIFx\_CTRL2n field descriptions

Field	Description
31–24 RSRVD5	This field is reserved. Reserved bits. Write as 0.
23–21 OUTSTANDING_ REQS	This bitfield indicates the maximum number of outstanding transactions that eLCDIF should request when it is acting as a bus master. Default is 2 outstanding transactions.  0x0 <b>REQ_1</b> — 0x1 <b>REQ_2</b> — 0x2 <b>REQ_4</b> — 0x3 <b>REQ_8</b> — 0x4 <b>REQ_16</b> —
20 BURST_LEN_8	By default, when the eLCDIF is in the bus master mode, it will issue AXI bursts of length 16 (except when in packed 24 bpp mode, it will issue bursts of length 15). When this bit is set to 1, the block will issue bursts of length 8 (except when in packed 24 bpp mode, it will issue bursts of length 9). Note that this bitfield is only applicable when LCDIF_MASTER is set to 1.
19 RSRVD4	This field is reserved. Reserved bits. Write as 0.
18–16 ODD_LINE_ PATTERN	This field determines the order of the RGB components of each pixel in ODD lines (line numbers 1,3,5,...). This bitfield must be 0 in DVI mode.  0x0 <b>RGB</b> — 0x1 <b>RBG</b> — 0x2 <b>GBR</b> — 0x3 <b>GRB</b> —

Table continues on the next page...

## LCDIFx\_CTRL2n field descriptions (continued)

Field	Description
	0x4 <b>BRG</b> — 0x5 <b>BGR</b> —
15 RSRVD3	This field is reserved. Reserved bits. Write as 0.
14–12 EVEN_LINE_ PATTERN	This field determines the order of the RGB components of each pixel in EVEN lines (line numbers 2,4,6,...). This bitfield must be 0 in DVI mode.  0x0 <b>RGB</b> — 0x1 <b>RBG</b> — 0x2 <b>GBR</b> — 0x3 <b>GRB</b> — 0x4 <b>BRG</b> — 0x5 <b>BGR</b> —
11 RSRVD2	This field is reserved. Reserved bits. Write as 0.
10 READ_PACK_DIR	The default value of 0 indicates data is stored in the little endian format. When LCD_DATABUS_WIDTH is 8-bit, this bit provides the option of rearranging the data byte-wise in the big endian format. For example, if READ_MODE_NUM_PACKED_SUBWORDS = 3 and the order of incoming data is 0x11, 0x22 and 0x33, then setting this bit to 1 will cause the data to be stored as 0x00112233 as opposed to the default 0x00332211. This operation occurs after the shifting operation done by SHIFT_NUM_BITS bitfield.
9 READ_MODE_ OUTPUT_IN_ RGB_FORMAT	Setting this bit will enable the eLCDIF to convert the incoming data to the RGB format given by WORD_LENGTH bitfield. This feature is not available when WORD_LENGTH is set to 8 bits. eLCDIF performs this operation of converting to RGB format after the endianness has been determined by the READ_PACK_DIR bitfield.
8 READ_MODE_6_ BIT_INPUT	Setting this bit to 1 indicates to eLCDIF that even though LCD_DATABUS_WIDTH is set to 8 bits, the input data is actually only 6 bits wide and exists on D5-D0.
7 RSRVD1	This field is reserved. Reserved bits. Write as 0.
6–4 READ_MODE_ NUM_PACKED_ SUBWORDS	Indicates the number of valid 8/16/18/24-bit subwords that will be packed into the 32-bit word in read mode. The subword size (8, 16, 18 or 24 bits) is determined by the LCD_DATABUS_WIDTH field. The swizzle operation is performed after READ_MODE_NUM_PACKED_SUBWORDS number of subwords has been received and stored in little-endian format. For example, if LCD_DATABUS_WIDTH is set to 8-bit and data to be read back has to be stored in memory in 24-bit unpacked RGB format, set READ_MODE_NUM_PACKED_SUBWORDS to 0x3 so that each 32-bit word will contain only 3 valid bytes (RGB). Maximum value of READ_MODE_NUM_PACKED_SUBWORDS is 4 for 8-bit databus, 2 for 16-bit databus and 1 for 18/24-bit databus.
3–1 INITIAL_DUMMY_ READ	The value in this field determines the number of dummy 8/16/18/24-bit subwords that have to be read back from the LCD panel/controller. They will then not be stored in the read FIFO.
0 RSRVD0	This field is reserved. Reserved bits. Write as 0.

### 13.2.6.4 eLCDIF Horizontal and Vertical Valid Data Count Register (LCDIFx\_TRANSFER\_COUNT)

This register tells the eLCDIF how much data will be sent for this frame, or transaction. The total number of words is a product of the V\_COUNT and H\_COUNT fields. The word size is specified by the WORD\_LENGTH field.

This register gives the dimensions of the input frame. For normal operation, but V\_COUNT and H\_COUNT should be non-zero.

Address: Base address + 30h offset

#### LCDIFx\_TRANSFER\_COUNT field descriptions

Field	Description
31-16 V_COUNT	Number of horizontal lines per frame which contain valid data. In DOTCLK mode, V_COUNT should be the same as the number of active horizontal lines in a progressive frame. In DVI mode, V_COUNT should be the number of active horizontal lines per frame, and not per field.
H_COUNT	Total valid data (pixels) in each horizontal line. The data size is given by the WORD_LENGTH. When input data is in YCbCr 4:2:2 format (YCBCR422_INPUT is 1), H_COUNT should be the number of 32-bit words that should be fetched by the block and the BYTE_PACKING_FORMAT should be 0xF. In 24-bit packed format (WORD_LENGTH=0x3, BYTE_PACKING_FORMAT=0xF), the H_COUNT must be a multiple of 4 pixels. In 16-bit packed format (WORD_LENGTH=0x0, BYTE_PACKING_FORMAT=0xF), the H_COUNT must be a multiple of 2 pixels.

### 13.2.6.5 LCD Interface Current Buffer Address Register (LCDIFx\_CUR\_BUF)

This register indicates the address of the current frame being transmitted by eLCDIF.

When the eLCDIF is behaving as a master, this address points to the address of the current frame of data being sent out via the LCDIF. When the current frame is done, the LCDIF block will assert the cur\_frame\_done interrupt for software to take action. The block will also copy the LCDIF\_NEXT\_BUF\_ADDR into this bitfield so that the software can program the next frame address into the LCDIF\_NEXT\_BUF\_ADDR bitfield. This address must always be double-word aligned.

Address: Base address + 40h offset

### LCDIFx\_CUR\_BUF field descriptions

Field	Description
ADDR	Address of the current frame being transmitted by eLCDIF.

#### 13.2.6.6 LCD Interface Next Buffer Address Register (LCDIFx\_NEXT\_BUF)

This register indicates the address of next frame that will be transmitted by eLCDIF.

When the eLCDIF is behaving as a master, this address points to the address of the next frame of data that will be sent out via the eLCDIF. It is up to the software to make sure that this register is programmed before the end of the current frame, otherwise it might result in old data going out the eLCDIF. This address must always be double-word aligned.

Address: Base address + 50h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### LCDIFx\_NEXT\_BUF field descriptions

Field	Description
ADDR	Address of the next frame that will be transmitted by eLCDIF.

#### 13.2.6.7 LCD Interface Timing Register (LCDIFx\_TIMING)

The LCD interface timing register controls the various setup and hold times enforced by the LCD interface in the 6800/8080 MPU and VSYNC modes of operation.

The values used in this register are dependent on the particular LCD controller used, consult the users manual for the particular controller for required timings. Each field of the register must be non-zero, therefore the minimum value is: 0x01010101. NOTE: the timings are not automatically adjusted if the CLK\_DIS\_LCDIFn frequency changes—it may be necessary to adjust the timings if CLK\_DIS\_LCDIFn changes. NOTE: Each field in this register must be non-zero for the MPU and VSYNC modes to function. The settings in this register do not affect the DOTCLK and DVI modes.

Address: Base address + 60h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	CMD_HOLD				CMD_SETUP				DATA_HOLD				DATA_SETUP																			
W	CMD_HOLD				CMD_SETUP				DATA_HOLD				DATA_SETUP																			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### LCDIFx\_TIMING field descriptions

Field	Description
31–24 CMD_HOLD	Number of CLK_DIS_LCDIFn cycles that the DCn signal is active after CEn is deasserted.
23–16 CMD_SETUP	Number of CLK_DIS_LCDIFn cycles that the DCn signal is active before CEn is asserted.
15–8 DATA_HOLD	Data bus hold time in CLK_DIS_LCDIFn cycles. Also the time that the data strobe is deasserted in a cycle
DATA_SETUP	Data bus setup time in CLK_DIS_LCDIFn cycles. Also the time that the data strobe is asserted in a cycle.

### 13.2.6.8 eLCDIF VSYNC Mode and Dotclk Mode Control Register0 (LCDIFx\_VDCTRL0n)

This register is used to control the VSYNC and DOTCLK modes of the LCDIF so as to work with different types of LCDs like moving picture displays and delta pixel displays.

This register gives general programmability to the VSYNC signal including polarity, direction, pulse width, etc.

Address: Base address + 70h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved								Reserved							
W	Reserved								VSYNC_PERIOD_UNIT	VSYNC_PULSE_WIDTH_UNIT	HALF_LINE	HALF_LINE_MODE	VSYNC_PULSE_WIDTH			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	VSYNC_PULSE_WIDTH															
W	VSYNC_PULSE_WIDTH															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### LCDIFx\_VDCTRL0n field descriptions

Field	Description
31–30 RSRVD2	This field is reserved. Reserved bits. Write as 0.

Table continues on the next page...

## LCDIFx\_VDCTRL0n field descriptions (continued)

Field	Description
29 VSYNC_OEB	0 means the VSYNC signal is an output, 1 means it is an input. Should be set to 0 in the DOTCLK mode.  0x0 <b>VSYNC_OUTPUT</b> — The VSYNC pin is in the output mode and the VSYNC signal has to be generated by the eLCDIF block.  0x1 <b>VSYNC_INPUT</b> — The VSYNC pin is in the input mode and the LCD controller sends the VSYNC signal to the block.
28 ENABLE_PRESENT	Setting this bit to 1 will make the hardware generate the ENABLE signal in the DOTCLK mode, thereby making it the true RGB interface along with the remaining three signals VSYNC, HSYNC and DOTCLK.
27 VSYNC_POL	Default 0 active low during VSYNC_PULSE_WIDTH time and will be high during the rest of the VSYNC period. Set it to 1 to invert the polarity.
26 HSYNC_POL	Default 0 active low during HSYNC_PULSE_WIDTH time and will be high during the rest of the HSYNC period. Set it to 1 to invert the polarity.
25 DOTCLK_POL	Default is data launched at negative edge of DOTCLK and captured at positive edge. Set it to 1 to invert the polarity. Set it to 0 in DVI mode.
24 ENABLE_POL	Default 0 active low during valid data transfer on each horizontal line.
23–22 RSRVD1	This field is reserved. Reserved bits. Write as 0.
21 VSYNC_PERIOD_UNIT	Default 0 for counting VSYNC_PERIOD in terms of CLK_DIS_LCDIFn cycles. Set it to 1 to count in terms of complete horizontal lines. CLK_DIS_LCDIFn cycles should be used in the VSYNC mode, while horizontal line should be used in the DOTCLK mode.
20 VSYNC_PULSE_WIDTH_UNIT	Default 0 for counting VSYNC_PULSE_WIDTH in terms of CLK_DIS_LCDIFn cycles. Set it to 1 to count in terms of complete horizontal lines.
19 HALF_LINE	Setting this bit to 1 will make the total VSYNC period equal to the VSYNC_PERIOD field plus half the HORIZONTAL_PERIOD field (i.e. VSYNC_PERIOD field plus half horizontal line), otherwise it is just VSYNC_PERIOD. Should be only used in the DOTCLK mode, not in the VSYNC interface mode.
18 HALF_LINE_MODE	When this bit is 0, the first field (VSYNC period) will end in half a horizontal line and the second field will begin with half a horizontal line. When this bit is 1, all fields will end with half a horizontal line, and none will begin with half a horizontal line.
VSYNC_PULSE_WIDTH	Number of units for which VSYNC signal is active. For the DOTCLK mode, the unit is determined by the VSYNC_PULSE_WIDTH_UNIT. If the VSYNC_PULSE_WIDTH_UNIT is 0 for DOTCLK mode, VSYNC_PULSE_WIDTH must be less than HSYNC_PERIOD. For the VSYNC interface mode, it should be in terms of number of CLK_DIS_LCDIFn cycles only.

### 13.2.6.9 eLCDIF VSYNC Mode and Dotclk Mode Control Register1 (LCDIFx\_VDCTRL1)

This register is used to control the VSYNC signal in the VSYNC and DOTCLK modes of the block.

This register determines the period and duty cycle of the VSYNC signal when it is generated in the block.

## Enhanced LCD Interface (eLCDIF)

Address: Base address + 80h offset

### LCDIFx\_VDCTRL1 field descriptions

Field	Description
VSYNC_PERIOD	Total number of units between two positive or two negative edges of the VSYNC signal. If HALF_LINE is set, it is implicitly calculated to be VSYNC_PERIOD plus half HSYNC_PERIOD.

### 13.2.6.10 LCDIF VSYNC Mode and Dotclk Mode Control Register2 (LCDIFx\_VDCTRL2)

This register is used to control the HSYNC signal in the DOTCLK mode of the block.

This register determines the period and duty cycle of the HSYNC signal when it is generated in the block.

Address: Base address + 90h offset

### LCDIFx\_VDCTRL2 field descriptions

Field	Description
31–18 HSYNC_PULSE_WIDTH	Number of CLK_DIS_LCDIFn cycles for which HSYNC signal is active.
HSYNC_PERIOD	Total number of CLK_DIS_LCDIFn cycles between two positive or two negative edges of the HSYNC signal.

### 13.2.6.11 eLCDIF VSYNC Mode and Dotclk Mode Control Register3 (LCDIFx\_VDCTRL3)

This register is used to determine the vertical and horizontal wait counts.

This register determines the back porches of HSYNC and VSYNC signals when they are generated by the block.

Address: Base address + A0h offset

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**LCDIFx\_VDCTRL3 field descriptions**

Field	Description
31–30 RSRVD0	This field is reserved. Reserved bits, write as 0.
29 MUX_SYNC_SIGNALS	When this bit is set, the eLCDIF block will internally mux HSYNC with LCD_D14, DOTCLK with LCD_D13 and ENABLE with LCD_D12, otherwise these signals will go out on separate pins. This feature can be used to maintain backward compatible with 37xx.
28 VSYNC_ONLY	This bit must be set to 1 in the VSYNC mode of operation, and 0 in the DOTCLK mode of operation.
27–16 HORIZONTAL_WAIT_CNT	In the DOTCLK mode, wait for this number of clocks from falling edge (or rising if HSYNC_POL is 1) of HSYNC signal to account for horizontal back porch plus the number of DOTCLKs before the moving picture information begins.
VERTICAL_WAIT_CNT	In the VSYNC interface mode, wait for this number of CLK_DIS_LCDIFn cycles from the falling VSYNC edge (or rising if VSYNC_POL is 1) before starting LCD transactions and is applicable only if WAIT_FOR_VSYNC_EDGE is set. Minimum is CMD_SETUP+5. In the DOTCLK mode, it accounts for the vertical back porch lines plus the number of horizontal lines before the moving picture begins. The unit for this parameter is inherently the same as the VSYNC_PERIOD_UNIT.

**13.2.6.12 eLCDIF VSYNC Mode and Dotclk Mode Control Register4 (LCDIFx\_VDCTRL4)**

This register is used to control the DOTCLK mode of the block.

This register determines the active data in each horizontal line in the DOTCLK mode. Note that the total number of active horizontal lines in the DOTCLK mode is the same as the V\_COUNT bitfield in the LCDIF\_TRANSFER\_COUNT register.

## Enhanced LCD Interface (eLCDIF)

Address: Base address + B0h offset

### LCDIFx\_VDCTRL4 field descriptions

Field	Description
31–29 DOTCLK_DLY_SEL	This bitfield selects the amount of time by which the DOTCLK signal should be delayed before coming out of the LCD_DOTCK pin. 0 = 2ns; 1=4ns;2=6ns;3=8ns. Remaining values are reserved.
28–19 RSRVD0	This field is reserved. Reserved bits, write as 0.
18 SYNC_SIGNALS_ON	Set this field to 1 if the LCD controller requires that the VSYNC or VSYNC/HSYNC/DOTCLK control signals should be active at least one frame before the data transfers actually start and remain active at least one frame after the data transfers end. The hardware does not count the number of frames automatically. Rather, the VSYNC edge interrupt can be monitored by software to count the number of frames that have occurred after this bit is set and then the RUN bit can be set to start the data transactions. This bit must always be set in the DOTCLK mode of operation, and it must be set in the VSYNC mode of operation when VSYNC signal is an output.
DOTCLK_H_VALID_DATA_CNT	Total number of CLK_DIS_LCDIFn cycles on each horizontal line that carry valid data in DOTCLK mode.

### 13.2.6.13 Digital Video Interface Control0 Register (LCDIFx\_DVICTRL0)

The Digital Video interface Control0 register provides the overall control of the Digital Video interface.

This register gives information about the horizontal active, horizontal blanking and total number of lines in the ITU-R BT.656 interface.

#### EXAMPLE

```
//525/60 video system
```

```

HW_LCDIF_DVICTRL0_H_ACTIVE_CNT_WR(0x5A0); //1440
HW_LCDIF_DVICTRL0_H_BLANKING_CNT_WR(0x106); //262
//625/50 video system
HW_LCDIF_DVICTRL0_H_ACTIVE_CNT_WR(0x5A0); //1440
HW_LCDIF_DVICTRL0_H_BLANKING_CNT_WR(0x112); //274

```

Address: Base address + C0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### LCDIFx\_DVICTRL0 field descriptions

Field	Description
31–28 RSRVD1	This field is reserved. Reserved bits, write as 0.
27–16 H_ACTIVE_CNT	Number of active video samples to be transmitted. (Mostly will be 1440 for both PAL and NTSC). Must always be a multiple of 4.
15–12 RSRVD0	This field is reserved. Reserved bits, write as 0.
H_BLANKING_CNT	Number of blanking samples to be inserted between EAV and SAV during horizontal blanking interval.

### 13.2.6.14 Digital Video Interface Control1 Register (LCDIFx\_DVICTRL1)

The Digital Video interface Control1 register provides the overall control of the Digital Video interface.

This register contains information about the Field1 start and end, and the Field2 start in the ITU-R BT.656 interface.

#### EXAMPLE

```

//525/60 video system
HW_LCDIF_DVICTRL1_F1_START_LINE_WR(0x4); //4
HW_LCDIF_DVICTRL1_F1_END_LINE_WR(0x109); //265
HW_LCDIF_DVICTRL1_F2_START_LINE_WR(0x10A); //266
//625/50 video system
HW_LCDIF_DVICTRL1_F1_START_LINE_WR(0x1); //1
HW_LCDIF_DVICTRL1_F1_END_LINE_WR(0x138); //312
HW_LCDIF_DVICTRL1_F2_START_LINE_WR(0x139); //313

```

Address: Base address + D0h offset

### LCDIFx\_DVICTRL1 field descriptions

Field	Description
31–30 RSRVD0	This field is reserved. Reserved bits, write as 0.
29–20 F1_START_LINE	Vertical line number from which Field 1 begins.
19–10 F1_END_LINE	Vertical line number at which Field1 ends.
F2_START_LINE	Vertical line number from which Field 2 begins.

### 13.2.6.15 Digital Video Interface Control2 Register (LCDIFx\_DVICTRL2)

The Digital Video interface Control2 register provides the overall control of the Digital Video interface.

This register contains information about the Field2 end, and the Vertical Blanking1 interval in the ITU-R BT.656 interface.

#### EXAMPLE

```
//525/60 video system
HW_LCDIF_DVICTRL2_F2_END_LINE_WR(0x3); //3
HW_LCDIF_DVICTRL2_V1_BLANK_START_LINE_WR(0x108); //264
HW_LCDIF_DVICTRL2_V1_BLANK_END_LINE_WR(0x11A); //282
//625/50 video system
HW_LCDIF_DVICTRL2_F2_END_LINE_WR(0x271); //625
HW_LCDIF_DVICTRL2_V1_BLANK_START_LINE_WR(0x137); //311
HW_LCDIF_DVICTRL2_V1_BLANK_END_LINE_WR(0x14F); //335
```

Address: Base address + E0h offset

### LCDIFx\_DVICTRL2 field descriptions

Field	Description
31–30 RSRVD0	This field is reserved. Reserved bits, write as 0.
29–20 F2_END_LINE	Vertical line number at which Field 2 ends.
19–10 V1_BLANK_START_LINE	Vertical line number towards the end of Field1 where first Vertical Blanking interval starts.
V1_BLANK_END_LINE	Vertical line number in the beginning part of Field2 where first Vertical Blanking interval ends.

### 13.2.6.16 Digital Video Interface Control3 Register (LCDIFx\_DVICTRL3)

The Digital Video interface Control3 register provides the overall control of the Digital Video interface.

This register contains information about the Vertical Blanking2 interval in the ITU-R BT. 656 interface.

#### EXAMPLE

```
//525/60 video system
HW_LCDIF_DVICTRL3_V2_BLANK_START_LINE_WR(0x1); //1
HW_LCDIF_DVICTRL3_V2_BLANK_END_LINE_WR(0x13); //19
HW_LCDIF_DVICTRL0_V_LINES_CNT_WR(0x20D); //525
//625/50 video system
HW_LCDIF_DVICTRL3_V2_BLANK_START_LINE_WR(0x270); //624
HW_LCDIF_DVICTRL3_V2_BLANK_END_LINE_WR(0x16); //22
HW_LCDIF_DVICTRL0_V_LINES_CNT_WR(0x271); //625
```

Address: Base address + F0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### LCDIFx\_DVICTRL3 field descriptions

Field	Description
31–30 RSRVD0	This field is reserved. Reserved bits, write as 0.

Table continues on the next page...

**LCDIFx\_DVICTRL3 field descriptions (continued)**

Field	Description
29–20 V2_BLANK_START_LINE	Vertical line number towards the end of Field2 where second Vertical Blanking interval starts.
19–10 V2_BLANK_END_LINE	Vertical line number in the beginning part of Field1 where second Vertical Blanking interval ends.
V_LINES_CNT	Total number of vertical lines per frame (generally 525 or 625)

**13.2.6.17 Digital Video Interface Control4 Register (LCDIFx\_DVICTRL4)**

The Digital Video interface Control4 register provides the overall control of the Digital Video interface.

This register is used to add side borders to the output if the input frame width is less than 720 pixels.

**EXAMPLE**

```
//If input frame has only 640 pixels per line, but output is supposed to have
720 pixels per line.
HW_LCDIF_DVICTRL4_H_FILL_CNT_WR(0x50); //80
HW_LCDIF_DVICTRL4_Y_FILL_VALUE_WR(0x10); //16
HW_LCDIF_DVICTRL4_CB_FILL_VALUE_WR(0x80); //128
HW_LCDIF_DVICTRL4_CR_FILL_VALUE_WR(0x80); //128
```

Address: Base address + 100h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Y_FILL_VALUE								CB_FILL_VALUE								CR_FILL_VALUE								H_FILL_CNT							
W	0								0								0								0							
Reset	0								0								0								0							

**LCDIFx\_DVICTRL4 field descriptions**

Field	Description
31–24 Y_FILL_VALUE	Value of Y component of filler data
23–16 CB_FILL_VALUE	Value of CB component of filler data
15–8 CR_FILL_VALUE	Value of CR component of filler data.
H_FILL_CNT	Number of active video samples that have to be filled with the filler data in the front and back portions of the active horizontal interval. Must be a multiple of 4. This field will have to be programmed if the input frame has less than 720 pixels per line.

### 13.2.6.18 RGB to YCbCr 4:2:2 CSC Coefficient0 Register (LCDIFx\_CSC\_COEFF0)

LCDIF\_CSC\_COEFF0 register provides overall control over color space conversion from RGB to 4:2:2 YCbCr. The equations for the conversion are given by:  $Y = C0 * R + C1 * G + C2 * B + Y\_offset$   $Cb = C3 * R + C4 * G + C5 * B + CbCr\_offset$   $Cr = C6 * R + C7 * G + C8 * B + CbCr\_offset$

This register carries programming information about RGB to YCbCr 4:2:2 CSC.

#### EXAMPLE

```
HW_LCDIF_CSC_COEFF0_C0_WR(0x41) ; // 0.257x256=65
HW_LCDIF_CSC_COEFF0_CSC_SUBSAMPLE_FILTER_WR(0x3) ;
```

Address: Base address + 110h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved								C0							
W	Reserved								C0							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved													CSC_		
W	Reserved													SUBSAMPL		
														E_FILTER		
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### LCDIFx\_CSC\_COEFF0 field descriptions

Field	Description
31–26 RSRVD1	This field is reserved. Reserved bits, write as 0.
25–16 C0	Two's complement red multiplier coefficient for Y
15–2 RSRVD0	This field is reserved. Reserved bits, write as 0.
CSC_	This register describes the filtering and subsampling scheme to be performed on the chroma components in order to convert from YCbCr 4:4:4 to YCbCr 4:2:2 space. Note that the following descriptions apply individually to Cb and Cr.
SUBSAMPLE_	
FILTER	
0x0	<b>SAMPLE_AND_HOLD</b> — No filtering, simply keep every chroma value for samples numbered 2n and discard chroma values associated with all samples numbered 2n+1.
0x1	<b>RSRVD</b> — Reserved
0x2	<b>INTERSTITIAL</b> — Chroma samples numbered 2n and 2n+1 are averaged (weights 1/2, 1/2) and that chroma value replaces the two chroma values at 2n and 2n+1. This chroma now exists horizontally halfway between the two luma samples.
0x3	<b>COSITED</b> — Chroma samples numbered 2n-1, 2n, and 2n+1 are averaged (weights 1/4, 1/2, 1/4) and that chroma value exists at the same site as the luma sample numbered 2n and the chroma samples at 2n+1 are discarded.

### 13.2.6.19 RGB to YCbCr 4:2:2 CSC Coefficient1 Register (LCDIFx\_CSC\_COEFF1)

LCDIF\_CSC\_COEFF1 register provides overall control over color space conversion from RGB to 4:2:2 YCbCr. The equations for the conversion are given by:  $Y = C0 * R + C1 * G + C2 * B + Y\_offset$   $Cb = C3 * R + C4 * G + C5 * B + CbCr\_offset$   $Cr = C6 * R + C7 * G + C8 * B + CbCr\_offset$

This register carries programming information about RGB to YCbCr 4:2:2 CSC.

#### EXAMPLE

```
HW_LCDIF_CSC_COEFF1_C1_WR(0x81); //0.504x256=129
HW_LCDIF_CSC_COEFF1_C2_WR(0x19); //0.098x256=25
```

Address: Base address + 120h offset

#### LCDIFx\_CSC\_COEFF1 field descriptions

Field	Description
31–26 RSRVD1	This field is reserved. Reserved bits, write as 0.
25–16 C2	Two's complement blue multiplier coefficient for Y
15–10 RSRVD0	This field is reserved. Reserved bits, write as 0.
C1	Two's complement green multiplier coefficient for Y

### 13.2.6.20 RGB to YCbCr 4:2:2 CSC Coefficient2 Register (LCDIFx\_CSC\_COEFF2)

LCDIF\_CSC\_COEFF2 register provides overall control over color space conversion from RGB to 4:2:2 YCbCr. The equations for the conversion are given by:  $Y = C0 * R + C1 * G + C2 * B + Y\_offset$   $Cb = C3 * R + C4 * G + C5 * B + CbCr\_offset$   $Cr = C6 * R + C7 * G + C8 * B + CbCr\_offset$

This register carries programming information about RGB to YCbCr 4:2:2 CSC.

#### EXAMPLE

```
HW_LCDIF_CSC_COEFF2_C3_WR(0x3DB); //-0.148x256=-37
HW_LCDIF_CSC_COEFF2_C4_WR(0x3B6); //-0.291x256=-74
```

Address: Base address + 130h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### LCDIFx\_CSC\_COEFF2 field descriptions

Field	Description
31–26 RSRVD1	This field is reserved. Reserved bits, write as 0.
25–16 C4	Two's complement green multiplier coefficient for Cb
15–10 RSRVD0	This field is reserved. Reserved bits, write as 0.
C3	Two's complement red multiplier coefficient for Cb

### 13.2.6.21 RGB to YCbCr 4:2:2 CSC Coefficient3 Register (LCDIFx\_CSC\_COEFF3)

LCDIF\_CSC\_COEFF3 register provides overall control over color space conversion from RGB to 4:2:2 YCbCr. The equations for the conversion are given by:  $Y = C0 * R + C1 * G + C2 * B + Y\_offset$   $Cb = C3 * R + C4 * G + C5 * B + CbCr\_offset$   $Cr = C6 * R + C7 * G + C8 * B + CbCr\_offset$

This register carries programming information about RGB to YCbCr 4:2:2 CSC.

#### EXAMPLE

```
HW_LCDIF_CSC_COEFF3_C5_WR(0x70); //0.439x256=112
HW_LCDIF_CSC_COEFF3_C6_WR(0x70); //0.439x256=112
```

Address: Base address + 140h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### LCDIFx\_CSC\_COEFF3 field descriptions

Field	Description
31–26 RSRVD1	This field is reserved. Reserved bits, write as 0.

Table continues on the next page...

**LCDIFx\_CSC\_COEFF3 field descriptions (continued)**

Field	Description
25–16 C6	Two's complement red multiplier coefficient for Cr
15–10 RSRVD0	This field is reserved. Reserved bits, write as 0.
C5	Two's complement blue multiplier coefficient for Cb

**13.2.6.22 RGB to YCbCr 4:2:2 CSC Coefficient4 Register (LCDIFx\_CSC\_COEFF4)**

LCDIF\_CSC\_COEFF4 register provides overall control over color space conversion from RGB to 4:2:2 YCbCr. The equations for the conversion are given by:  $Y = C0 * R + C1 * G + C2 * B + Y\_offset$   $Cb = C3 * R + C4 * G + C5 * B + CbCr\_offset$   $Cr = C6 * R + C7 * G + C8 * B + CbCr\_offset$

This register carries programming information about RGB to YCbCr 4:2:2 CSC.

**EXAMPLE**

```
HW_LCDIF_CSC_COEFF4_C7_WR(0x3A2); // -0.368x256 = -94
HW_LCDIF_CSC_COEFF4_C8_WR(0x3EE); // -0.071x256 = -18
```

Address: Base address + 150h offset

**LCDIFx\_CSC\_COEFF4 field descriptions**

Field	Description
31–26 RSRVD1	This field is reserved. Reserved bits, write as 0.
25–16 C8	Two's complement blue multiplier coefficient for Cr
15–10 RSRVD0	This field is reserved. Reserved bits, write as 0.
C7	Two's complement green multiplier coefficient for Cr

### 13.2.6.23 RGB to YCbCr 4:2:2 CSC Offset Register (LCDIFx\_CSC\_OFFSET)

LCDIF\_CSC\_ register provides overall control over color space conversion from RGB to 4:2:2 YCbCr. The equations for the conversion are given by:  $Y = C0 * R + C1 * G + C2 * B + Y\_offset$   
 $Cb = C3 * R + C4 * G + C5 * B + CbCr\_offset$   
 $Cr = C6 * R + C7 * G + C8 * B + CbCr\_offset$

This register carries programming information about RGB to YCbCr 4:2:2 CSC.

Address: Base address + 160h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved							CBCR_OFFSET							Reserved							Y_OFFSET										
W	0							1							0							0										
Reset	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

#### LCDIFx\_CSC\_OFFSET field descriptions

Field	Description
31–25 RSRVD1	This field is reserved. Reserved bits, write as 0.
24–16 CBCR_OFFSET	Two's complement offset for the Cb and Cr components
15–9 RSRVD0	This field is reserved. Reserved bits, write as 0.
Y_OFFSET	Two's complement offset for the Y component

### 13.2.6.24 RGB to YCbCr 4:2:2 CSC Limit Register (LCDIFx\_CSC\_LIMIT)

LCDIF\_CSC\_CTRL0 register provides overall control over color space conversion from RGB to 4:2:2 YCbCr. The equations for the conversion are given by:  $Y = C0 * R + C1 * G + C2 * B + Y\_offset$   
 $Cb = C3 * R + C4 * G + C5 * B + CbCr\_offset$   
 $Cr = C6 * R + C7 * G + C8 * B + CbCr\_offset$

This register carries programming information about RGB to YCbCr 4:2:2 CSC. Note that the values in this register are unsigned.

#### EXAMPLE

```
HW_LCDIF_CSC_LIMIT_CBCR_MIN_WR(0x10); //16
HW_LCDIF_CSC_LIMIT_CBCR_MAX_WR(0xF0); //240
HW_LCDIF_CSC_LIMIT_Y_MIN_WR(0x10); //16
HW_LCDIF_CSC_LIMIT_Y_MAX_WR(0xEB); //235
```

## Enhanced LCD Interface (eLCDIF)

Address: Base address + 170h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### LCDIFx\_CSC\_LIMIT field descriptions

Field	Description
31–24 CBCR_MIN	Lower limit of Cb and Cr after RGB to 4:2:2 YCbCr conversion
23–16 CBCR_MAX	Upper limit of Cb and Cr after RGB to 4:2:2 YCbCr conversion
15–8 Y_MIN	Lower limit of Y after RGB to 4:2:2 YCbCr conversion
Y_MAX	Upper limit of Y after RGB to 4:2:2 YCbCr conversion

### 13.2.6.25 LCD Interface Data Register (LCDIFx\_DATA)

This register is used to transfer data using the PIO interface mode of operation. In MPU mode, data written to this register will be transferred out to the display device. When receiving data from the display, data is read from this register using PIO operations. During write operations, data can be written to this register (from the processor's perspective) as bytes, half-words (16 bits), or words (32 bits) as desired.

This register holds the 32-bit word written by the ARM platform into LCDIF. This data then gets sent out by the block across the interface.

Address: Base address + 180h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W	DATA_THREE								DATA_TWO								DATA_ONE								DATA_ZERO							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

### LCDIFx\_DATA field descriptions

Field	Description
31–24 DATA_THREE	Byte 3 (most significant byte) of data written to LCDIF.
23–16 DATA_TWO	Byte 2 of data written to eLCDIF.
15–8 DATA_ONE	Byte 1 of data written to eLCDIF.
DATA_ZERO	Byte 0 (least significant byte) of data written to eLCDIF.

### 13.2.6.26 Bus Master Error Status Register (LCDIFx\_BM\_ERROR\_STAT)

This register reflects the virtual address at which the AXI master received an error response from the slave.

When the BM\_ERROR\_IRQ is asserted, the address of the bus error is updated in the register.

Address: Base address + 190h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### LCDIFx\_BM\_ERROR\_STAT field descriptions

Field	Description
ADDR	Virtual address at which bus master error occurred.

### 13.2.6.27 CRC Status Register (LCDIFx\_CRC\_STAT)

This register reflects the CRC value of each frame sent out by eLCDIF. The CRC is done on the final output bus, so the value will be dependent on the LCD\_DATABUS\_WIDTH bitfield even if the input data is the same.

This register will be updated when the CUR\_FRAME\_DONE\_IRQ is asserted. In the case of DVI mode, the CRC is calculated for the entire frame, not separately for each field in the frame.

Address: Base address + 1A0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### LCDIFx\_CRC\_STAT field descriptions

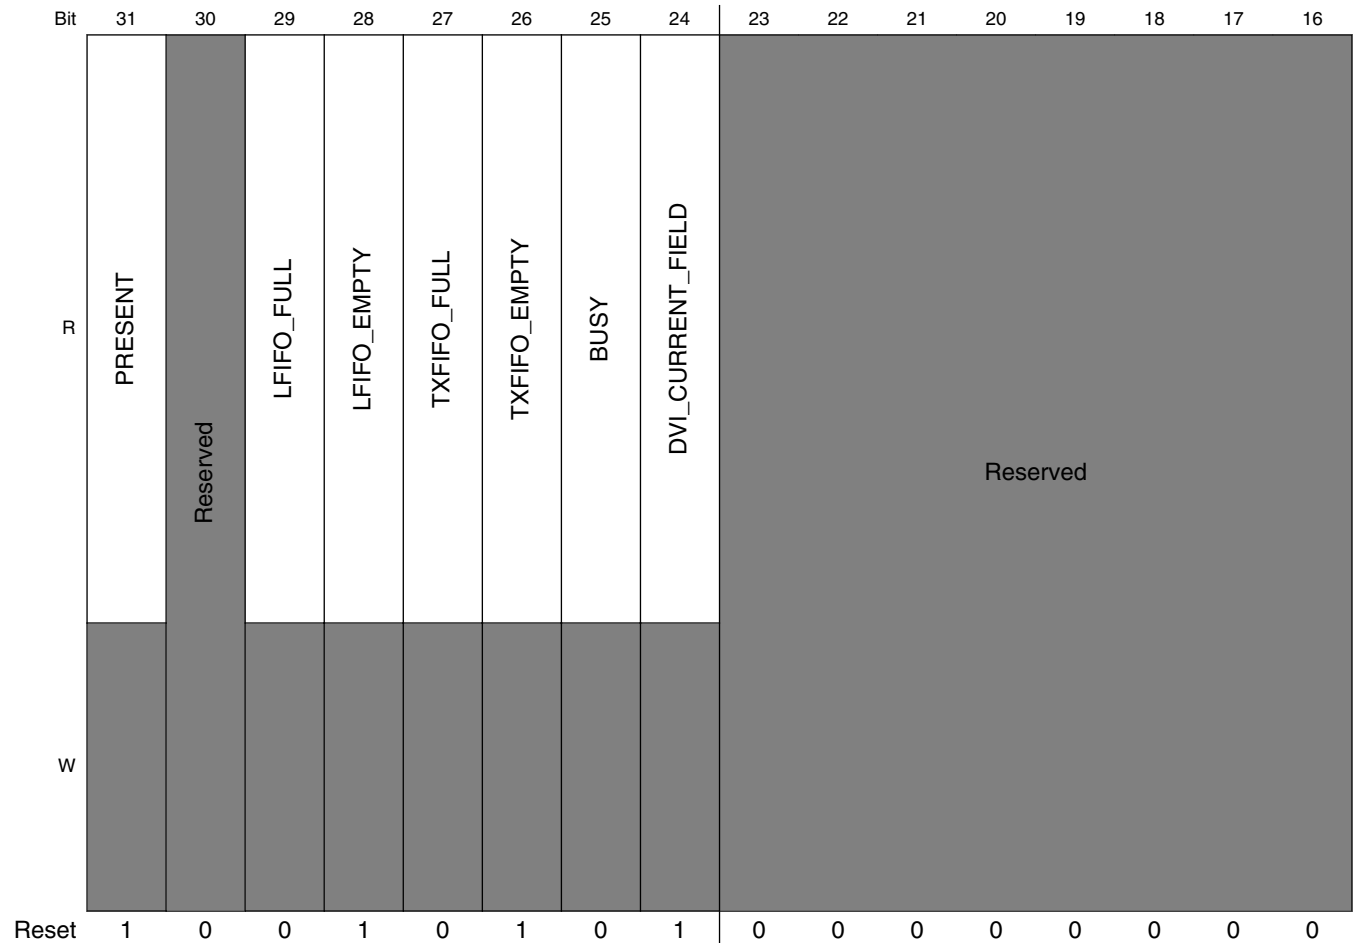

Field	Description
CRC_VALUE	Calculated CRC value.

### 13.2.6.28 LCD Interface Status Register (LCDIFx\_STAT)

The LCD interface status register can be used to check the current status of the eLCDIF block.

The LCD interface status register that contains read only views of some parameters or current state of the block.

Address: Base address + 1B0h offset

### LCDIFx\_STAT field descriptions

Field	Description
31 PRESENT	0: eLCDIF not present on this product 1: eLCDIF is present.
30 -	This field is reserved. Reserved.
29 LFIFO_FULL	Read only view of the signal that indicates that LCD read datapath FIFO is full, will be generally used in the write mode of the LCD interface.
28 LFIFO_EMPTY	Read only view of the signal that indicates that LCD read datapath FIFO is empty, will be generally used in the read mode of the LCD interface.
27 TXFIFO_FULL	Read only view of the signal that indicates that LCD write datapath FIFO is full, will be generally used in the write mode of the LCD interface.
26 TXFIFO_EMPTY	Read only view of the signal that indicates that LCD write datapath FIFO is empty, will be generally used in the read mode of the LCD interface.
25 BUSY	Read only view of the input busy signal from the external LCD controller.
24 DVI_CURRENT_FIELD	Read only view of the current field being transmitted. DVI_CURRENT_FIELD = 0 means field 1. DVI_CURRENT_FIELD = 1 means field 2.
23–9 RSRVDO	This field is reserved. Reserved bits. Write as 0.
LFIFO_COUNT	Read only view of the current count in Latency buffer (LFIFO).

### 13.2.6.29 LCD Interface Version Register (LCDIFx\_VERSION)

The LCD interface version register can be used to read the version of the eLCDIF IP being used in this SoC.

## Enhanced LCD Interface (eLCDIF)

The LCD interface debug register is for diagnostic use only.

Address: Base address + 1C0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0					
R	MAJOR								MINOR								STEP																				
W	[Shaded]																																				
Reset	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### LCDIFx\_VERSION field descriptions

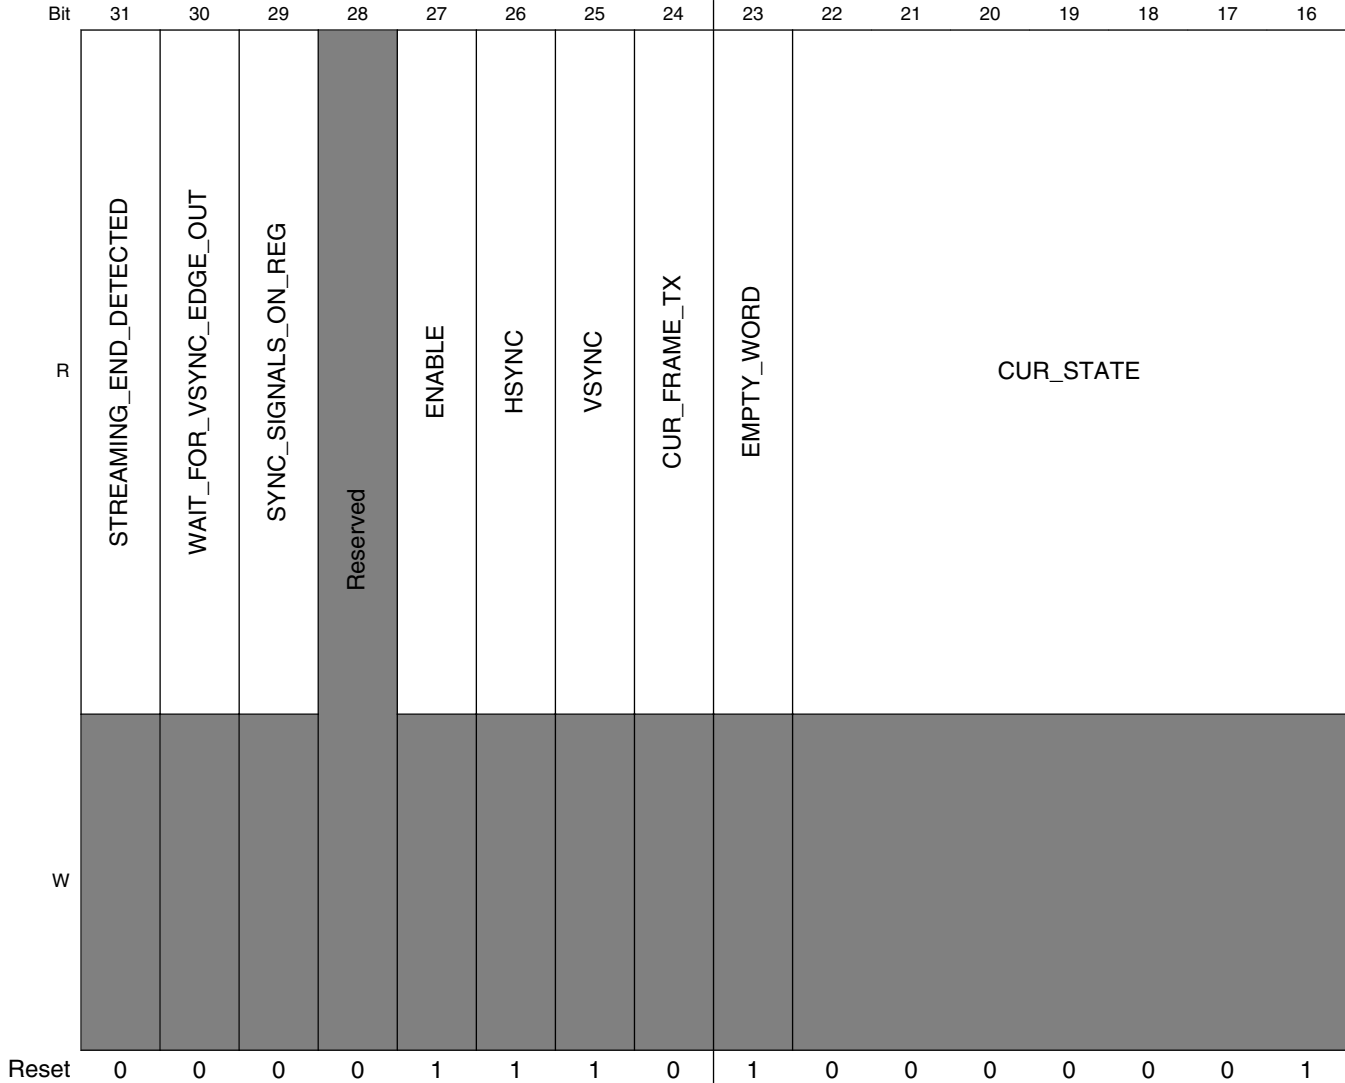

Field	Description
31–24 MAJOR	Fixed read-only value reflecting the MAJOR field of RTL version.
23–16 MINOR	Fixed read-only value reflecting the MINOR field of RTL version.
STEP	Fixed read-only value reflecting the stepping of RTL version.

### 13.2.6.30 LCD Interface Debug0 Register (LCDIFx\_DEBUG0)

The LCD interface debug0 register provides a diagnostic view of the state machine and other useful internal signals.

The LCD interface debug register is for diagnostic use only.

Address: Base address + 1D0h offset

## Enhanced LCD Interface (eLCDIF)

### LCDIFx\_DEBUG0 field descriptions

Field	Description
31 STREAMING_END_DETECTED	Read only view of the DOTCLK_MODE or DVI_MODE bit going from 1 to 0.
30 WAIT_FOR_VSYNC_EDGE_OUT	Read only view of WAIT_FOR_VSYNC_EDGE bit in the VSYNC mode after it comes out of the TXFIFO.
29 SYNC_SIGNALS_ON_REG	Read only view of internal sync_signals_on_reg signal.
28 -	This field is reserved. Reserved.
27 ENABLE	Read only view of ENABLE signal.

Table continues on the next page...

## LCDIFx\_DEBUG0 field descriptions (continued)

Field	Description
26 HSYNC	Read only view of HSYNC signal.
25 VSYNC	Read only view of VSYNC signal.
24 CUR_FRAME_TX	This bit is 1 for the time the current frame is being transmitted in the VSYNC mode. Useful for VSYNC mode debug.
23 EMPTY_WORD	Indicates that the current word is empty.
22–16 CUR_STATE	Read only view of the current state machine state in the current mode of operation.
15 PXP_LCDIF_B0_READY	Buffer0 ready signal issued by PXP.
14 PXP_B0_DONE	Buffer0 done signal issued by eLCDIF.
13 PXP_LCDIF_B1_READY	Buffer1 ready signal issued by PXP.
12 PXP_B1_DONE	Buffer1 done signal issued by eLCDIF.
11–10 CUR_REQ_STATE	Read only view of the request state machine.
9 MST_AVALID	Read only view of the mst_avalid signal issued by the AXI bus master.
8–4 MST_OUTSTANDING_REQS	Read only view of the current outstanding requests issued by the AXI bus master.
MST_WORDS	Read only view of the current bursts issued by the AXI bus master.

### 13.2.6.31 LCD Interface Debug1 Register (LCDIFx\_DEBUG1)

The LCD interface debug1 register provides a diagnostic view of the state machine and other useful internal signals.

The LCD interface debug register is for diagnostic use only.

Address: Base address + 1E0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	H_DATA_COUNT																V_DATA_COUNT															
W	0																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**LCDIFx\_DEBUG1 field descriptions**

Field	Description
31–16 H_DATA_COUNT	Read only view of the current state of the horizontal data counter.
V_DATA_COUNT	Read only view of the current state of the vertical data counter.

**13.2.6.32 LCD Interface Debug2 Register (LCDIFx\_DEBUG2)**

The LCD interface debug2 register provides a diagnostic view of the state machine and other useful internal signals.

The LCD interface debug register is for diagnostic use only.

Address: Base address + 1F0h offset

**LCDIFx\_DEBUG2 field descriptions**

Field	Description
MST_ADDRESS	Read only view of the current address issued by the AXI bus master.

**13.2.6.33 eLCDIF Threshold Register (LCDIFx\_THRES)**

This register is used to activate control signals when the number of pixels reaches the programmed threshold. These control signals, in turn, can be used to manipulate access priority or dynamically change the input clock frequency to meet the required pixel throughput.

Memory request priority threshold register.

Address: Base address + 200h offset

## LCDIFx\_THRES field descriptions

Field	Description
31–25 RSRVD2	This field is reserved. Reserved bits. Write as 0.
24–16 FASTCLOCK	This value should be set to a value of pixels, from 0 to 511. When the number of pixels in the input pixel FIFO is LESS than this value, the fast clock control output will be raised. This signal can be used to reduce the system bus clock frequency to save power during horizontal or vertical blanking intervals. This value should also be programmed to a value that is greater than the "PANIC" threshold value. This will allow a faster clock to recover the number of pixels in the FIFO before a "panic" level is encountered.
15–9 RSRVD1	This field is reserved. Reserved bits. Write as 0.
PANIC	This value should be set to a value of pixels from 0 to 511. When the number of pixels in the input pixel FIFO is less than this value, the internal panic control output will be raised. This signal can be used to raise the access eLCDIF's access priority.

### 13.2.6.34 eLCDIF AS Buffer Control Register (LCDIFx\_AS\_CTRL)

The Alpha Surface Parameter register provides additional controls for AS.

Address: Base address + 210h offset

**LCDIFx\_AS\_CTRL field descriptions**

Field	Description
31 CSI_VSYNC_ENABLE	When this bit is set by software, the LCDIF work as sync mode with CSI input.
30 CSI_VSYNC_POL	Default 0 active low during VSYNC_PULSE_WIDTH time and will be high during the rest of the VSYNC period. Set it to 1 to invert the polarity.

Table continues on the next page...

## LCDIFx\_AS\_CTRL field descriptions (continued)

Field	Description
29 CSI_VSYNC_MODE	this bit is set by software to decide which vsync generate mode. LCDIF vsync generate by internal counter when set to 0, LCDIF vsync delayed by each csi_vsync_in when set to 1; INT_SYNC_MODE = 0x0 LCDIF vsync generate by internal counter. EXT_SYNC_MODE = 0x1 LCDIF vsync delayed by each csi_vsync_in.
28 CSI_SYNC_ON_IRQ_EN	This bit is set to enable an interrupt when LCDIF lock with CSI vsync input.
27 CSI_SYNC_ON_IRQ	this bit is set by software to decide which vsync generate mode. LCDIF vsync generate by internal counter when set to 0, LCDIF vsync delayed by each csi_vsync_in when set to 1; INT_SYNC_MODE = 0x0 LCDIF vsync generate by internal counter. EXT_SYNC_MODE = 0x1 LCDIF vsync delayed by each csi_vsync_in.
26–24 RVDS1	Reserved, always set to zero.
23 PS_DISABLE	When this bit is set by software, the LCDIF will disable PS buffer data.
22–21 INPUT_DATA_SWIZZLE	This field specifies how to swap the bytes either in the HW_LCDIF_DATA register or those fetched by the AXI master part of LCDIF. The swizzle function is independent of the WORD_LENGTH bit. See the explanation of the HW_LCDIF_DATA below for names and definitions of data register fields. The supported swizzle configurations are: NO_SWAP = 0x0 No byte swapping.(Little endian) LITTLE_ENDIAN = 0x0 Little Endian byte ordering (same as NO_SWAP). BIG_ENDIAN_SWAP = 0x1 Big Endian swap (swap bytes 0, 3 and 1, 2). SWAP_ALL_BYTES = 0x1 Swizzle all bytes, swap bytes 0, 3 and 1, 2 (aka Big Endian). HWD_SWAP = 0x2 Swap half-words. HWD_BYTE_SWAP = 0x3 Swap bytes within each half-word.
20 ALPHA_INVERT	Setting this bit to logic 0 will not alter the alpha value. A logic 1 will invert the alpha value and apply (1-alpha) for image composition.
19–16 ROP	Indicates a raster operation to perform when enabled. Raster operations are enabled through the ALPHA_CTRL field. MASKAS = 0x0 AS AND PS MASKNOTAS = 0x1 nAS AND PS MASKASNOT = 0x2 AS AND nPS MERGEAS = 0x3 AS OR PS MERGENOTAS = 0x4 nAS OR PS MERGEASNOT = 0x5 AS OR nPS NOTCOPYAS = 0x6 nAS NOT = 0x7 nPS NOTMASKAS = 0x8 AS NAND PS NOTMERGEAS = 0x9 AS NOR PS XORAS = 0xA AS XOR PS NOTXORAS = 0xB AS XNOR PS

Table continues on the next page...

**LCDIFx\_AS\_CTRL field descriptions (continued)**

Field	Description
15–8 ALPHA	Alpha modifier used when the ALPHA_MULTIPLY or ALPHA_OVERRIDE values are programmed in REG_AS_CTRL[ALPHA_CTRL]. The output alpha value will either be replaced (ALPHA_OVERRIDE) or scaled (ALPHA_MULTIPLY) when selected.
7–4 FORMAT	Indicates the input buffer format for AS. ARGB8888 = 0x0 32-bit pixels with alpha RGB888 = 0x4 32-bit pixels without alpha (unpacked 24-bit format) ARGB1555 = 0x8 16-bit pixels with alpha ARGB4444 = 0x9 16-bit pixels with alpha RGB555 = 0xC 16-bit pixels without alpha RGB444 = 0xD 16-bit pixels without alpha RGB565 = 0xE 16-bit pixels without alpha
3 ENABLE_ COLORKEY	Indicates that colorkey functionality is enabled for this alpha surface. Pixels found in the alpha surface colorkey range will be displayed as transparent (the PS pixel will be used).
2–1 ALPHA_CTRL	Determines how the alpha value is constructed for this alpha surface. Indicates that the value in the ALPHA field should be used instead of the alpha values present in the input pixels. Embedded = 0x0 Indicates that the AS pixel alpha value will be used to blend the AS with PS. The ALPHA field is ignored. Override = 0x1 Indicates that the value in the ALPHA field should be used instead of the alpha values present in the input pixels. Multiply = 0x2 Indicates that the value in the ALPHA field should be used to scale all pixel alpha values. Each pixel alpha is multiplied by the value in the ALPHA field. ROPs = 0x3 Enable ROPs. The ROP field indicates an operation to be performed on the alpha surface and PS pixels.
0 AS_ENABLE	When this bit is set by software, the LCDIF will start fetching AS buffer data in bus master mode and combine it with another buffer.

**13.2.6.35 Alpha Surface Buffer Pointer (LCDIFx\_AS\_BUF)**

This register is used to indicate the base address of the AS buffer.

Address: Base address + 220h offset

**LCDIFx\_AS\_BUF field descriptions**

Field	Description
ADDR	Address pointer for the alpha surface 0 buffer.

### 13.2.6.36 LCDIFx\_AS\_NEXT\_BUF

When the LCDIF is behaving as a master, this address points to the address of the next frame of data that will be sent out via the LCDIF. It is upto the software to make sure that this register is programmed before the end of the current frame, otherwise it might result in old data going out the LCDIF. This address must always be double-word aligned.

Address: Base address + 230h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																																
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### LCDIFx\_AS\_NEXT\_BUF field descriptions

Field	Description
ADDR	Address of the next frame that will be transmitted by eLCDIF.

### 13.2.6.37 eLCDIF Overlay Color Key Low (LCDIFx\_AS\_CLRKEYLOW)

If a pixel in the current overlay image with a color that falls in the range from the ASCOLORKEYLOW to ASCOLORKEYHIGH range, it will use the PS pixel value for that location. Colorkey operations are higher priority than alpha or ROP operations.

Address: Base address + 240h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																																
W																																
Reset	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

#### LCDIFx\_AS\_CLRKEYLOW field descriptions

Field	Description
31–24 RSVD1	Reserved, always set to zero.
PIXEL	Low range of RGB color key applied to AS buffer

### 13.2.6.38 eLCDIF Overlay Color Key High (LCDIFx\_AS\_CLRKEYHIGH)

If a pixel in the current overlay image with a color that falls in the range from the ASCOLORKEYLOW to ASCOLORKEYHIGH range, it will use the PS pixel value for that location. Colorkey operations are higher priority than alpha or ROP operations.

Address: Base address + 250h offset

#### LCDIFx\_AS\_CLRKEYHIGH field descriptions

Field	Description
31–24 RSVD1	Reserved, always set to zero.
PIXEL	High range of RGB color key applied to AS buffer

### 13.2.6.39 LCD working insync mode with CSI for VSYNC delay (LCDIFx\_SYNC\_DELAY)

The LCDIF DOTCLK mode VSYNC will delay from CSI\_VSYNC as  $(V\_COUNT\_DELAY * HSYNC\_PERIOD + H\_COUNT\_DELAY)$  PIXCLK cycles

Address: Base address + 260h offset

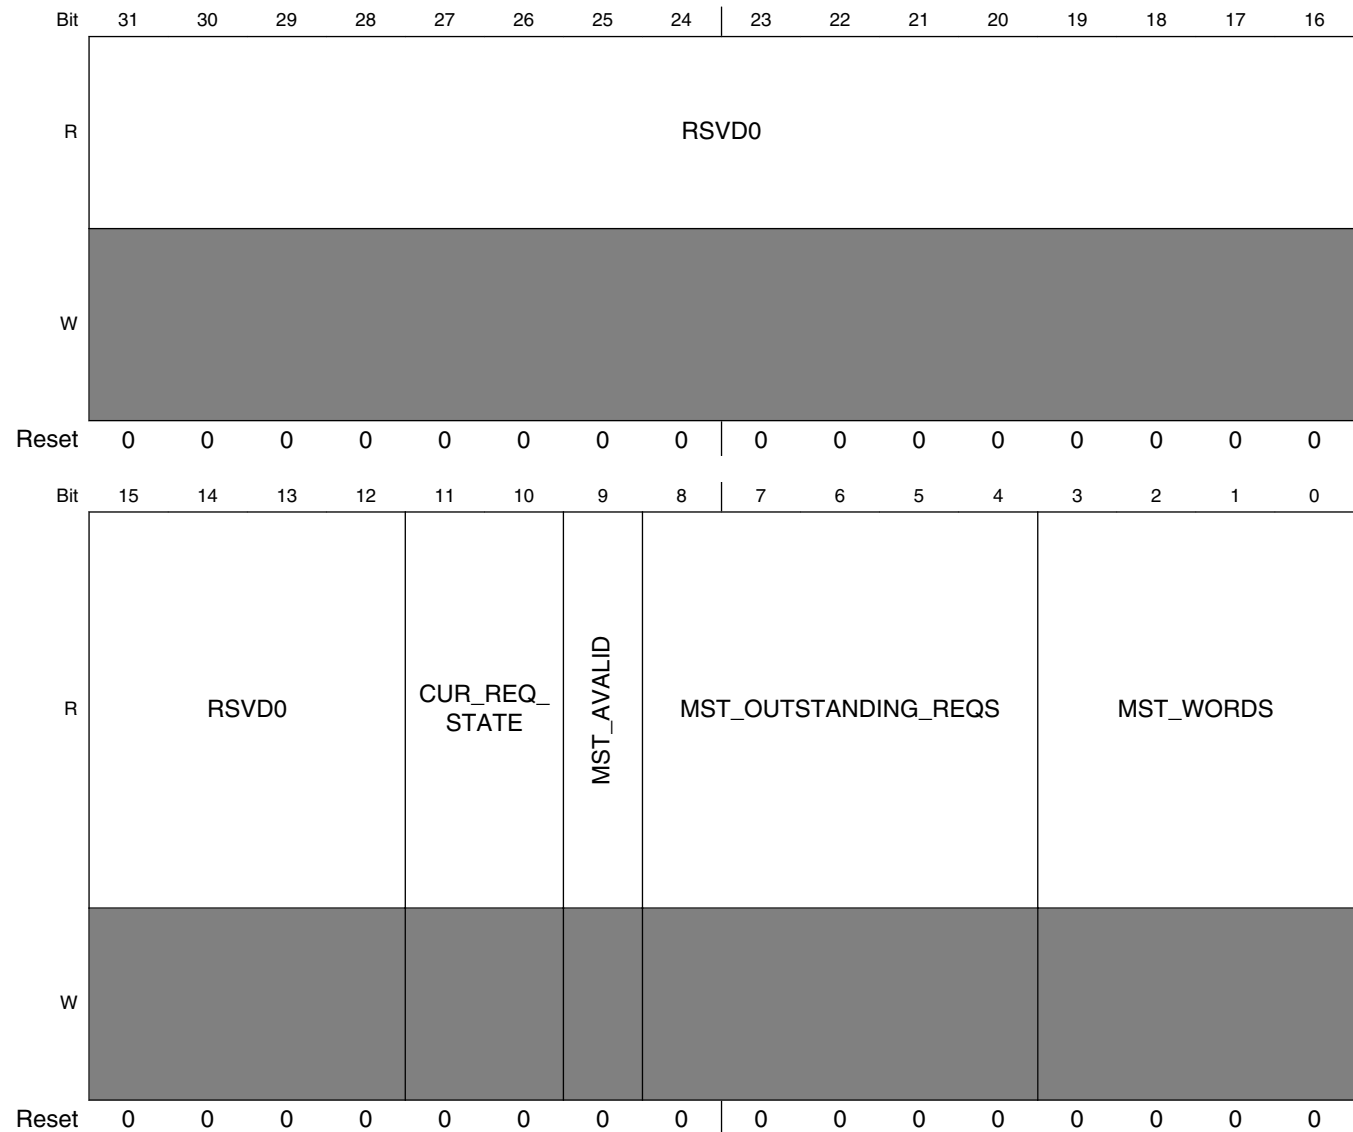

#### LCDIFx\_SYNC\_DELAY field descriptions

Field	Description
31–16 V_COUNT_DELAY	LCDIF VSYNC delayed counter for CSI_VSYNC.
H_COUNT_DELAY	LCDIF VSYNC delayed counter for CSI_VSYNC.

### 13.2.6.40 eLCDIF Interface Debug3 Register (LCDIFx\_DEBUG3)

The LCD interface debug register is for diagnostic use only.

Address: Base address + 270h offset

**LCDIFx\_DEBUG3 field descriptions**

Field	Description
31–12 RSVD0	Reserved bits, write as 0.

*Table continues on the next page...*

**LCDIFx\_DEBUG3 field descriptions (continued)**

Field	Description
11–10 CUR_REQ_STATE	Read only view of the request state machine
9 MST_AVALID	Read only view of the mst_avalid signal issued by the AXI bus master
8–4 MST_OUTSTANDING_REQS	Read only view of the current outstanding requests issued by the AXI bus master
MST_WORDS	Read only view of the current bursts issued by the AXI bus master.

**13.2.6.41 LCD Interface Debug4 (LCDIFx\_DEBUG4)**

The LCD interface debug register is for diagnostic use only.

Address: Base address + 280h offset

**LCDIFx\_DEBUG4 field descriptions**

Field	Description
31–16 H_DATA_COUNT	Read only view of the current AS state of the horizontal data counter.
V_DATA_COUNT	Read only view of the current AS state of the vertical data counter.

### 13.2.6.42 LCD Interface Debug5 (LCDIFx\_DEBUG5)

The LCD interface debug register is for diagnostic use only.

Address: Base address + 290h offset

#### LCDIFx\_DEBUG5 field descriptions

Field	Description
MST_ADDRESS	Read only view of the AS channel address issued by the AXI bus master.

## 13.3 CMOS Sensor Interface (CSI)

### 13.3.1 Overview

This chapter presents the CMOS Sensor Interface (CSI) architecture, operation principles, and programming model.

The CSI enables the chip to connect directly to external CMOS image sensors. CMOS image sensors are separated into two classes, dumb and smart. Dumb sensors are those that support only traditional sensor timing (Vertical SYNC and Horizontal SYNC) and output only Bayer and statistics data, while smart sensors support CCIR656 video decoder formats and perform additional processing of the image (for example, image compression, image pre-filtering, and various data output formats).

The capabilities of the CSI include:

- Configurable interface logic to support most commonly available CMOS sensors.
- Support for CCIR656 video interface as well as traditional sensor interface.
- 8-bit / 16-bit / 24-bit data port for YCbCr, YUV, or RGB data input.
- 8-bit / 10-bit / 16-bit data port for Bayer data input.
- Full control of 8-bit/pixel, 10-bit/pixel or 16-bit / pixel data format to 64-bitreceive FIFO packing.
- 256 x 64 FIFO to store received image pixel data.
- Receive FIFO overrun protection mechanism.

- Embedded DMA controllers to transfer data from receive FIFO or statistic FIFO through AHB bus.
- Support 2D DMA transfer from the receive FIFO to the frame buffers in the external memory.
- Support double buffering two frames in the external memory.
- Single interrupt source to interrupt controller from maskable interrupt sources: Start of Frame, End of Frame, Change of Field, FIFO full, FIFO overrun, DMA transfer done, CCIR error and AHB bus response error.
- Configurable master clock frequency output to sensor.
- Statistic data generation for Auto Exposure (AE) and Auto White Balance (AWB) control of the camera (only for Bayer data and 8-bit/pixel format).
- Supports simple deinterlacing of interlaced input.

### 13.3.2 External Signals

The table below describes the external signals for the CSI. The external signals are tied between the CSI module and an external CMOS sensor.

**Table 13-5. CSI External Signals**

Signal	Description	Pad	Mode	Direction
CSI_DATA00	Data Sensor Signal, part of 16-bit Sensor Data Bus (Bayer, YUV, YCrCb, RGB)	LCD1_DATA17	ALT3	I
CSI_DATA01	Data Sensor Signal, part of 16-bit Sensor Data Bus (Bayer, YUV, YCrCb, RGB)	LCD1_DATA16	ALT3	I
CSI_DATA02	Data Sensor Signal, part of 16-bit Sensor Data Bus (Bayer, YUV, YCrCb, RGB)	ECSPI1_SCLK	ALT3	I
		LCD1_DATA15	ALT3	
CSI_DATA03	Data Sensor Signal, part of 16-bit Sensor Data Bus (Bayer, YUV, YCrCb, RGB)	ECSPI1_MOSI	ALT3	I
		LCD1_DATA14	ALT3	
CSI_DATA04	Data Sensor Signal, part of 16-bit Sensor Data Bus (Bayer, YUV, YCrCb, RGB)	ECSPI1_MISO	ALT3	I
		LCD1_DATA13	ALT3	
CSI_DATA05	Data Sensor Signal, part of 16-bit Sensor Data Bus (Bayer, YUV, YCrCb, RGB)	ECSPI1_SS0	ALT3	I
		LCD1_DATA12	ALT3	
CSI_DATA06	Data Sensor Signal, part of 16-bit Sensor Data Bus (Bayer, YUV, YCrCb, RGB)	ECSPI2_SCLK	ALT3	I
		LCD1_DATA11	ALT3	
CSI_DATA07	Data Sensor Signal, part of 16-bit Sensor Data Bus (Bayer, YUV, YCrCb, RGB)	ECSPI2_MOSI	ALT3	I
		LCD1_DATA10	ALT3	

*Table continues on the next page...*

**Table 13-5. CSI External Signals (continued)**

Signal	Description	Pad	Mode	Direction
CSI_DATA08	Data Sensor Signal, part of 16-bit Sensor Data Bus (Bayer, YUV, YCrCb, RGB)	ECSPI2_MISO	ALT3	I
		LCD1_DATA09	ALT3	
CSI_DATA09	Data Sensor Signal, part of 16-bit Sensor Data Bus (Bayer, YUV, YCrCb, RGB)	ECSPI2_SS0	ALT3	I
		LCD1_DATA08	ALT3	
CSI_DATA10	Data Sensor Signal, part of 16-bit Sensor Data Bus (Bayer, YUV, YCrCb, RGB)	LCD1_DATA23	ALT3	I
CSI_DATA11	Data Sensor Signal, part of 16-bit Sensor Data Bus (Bayer, YUV, YCrCb, RGB)	LCD1_DATA22	ALT3	I
CSI_DATA12	Data Sensor Signal, part of 16-bit Sensor Data Bus (Bayer, YUV, YCrCb, RGB)	LCD1_DATA21	ALT3	I
CSI_DATA13	Data Sensor Signal, part of 16-bit Sensor Data Bus (Bayer, YUV, YCrCb, RGB)	LCD1_DATA20	ALT3	I
CSI_DATA14	Data Sensor Signal, part of 16-bit Sensor Data Bus (Bayer, YUV, YCrCb, RGB)	LCD1_DATA19	ALT3	I
CSI_DATA15	Data Sensor Signal, part of 16-bit Sensor Data Bus (Bayer, YUV, YCrCb, RGB)	LCD1_DATA18	ALT3	I
CSI_DATA16	Data Sensor Signal, part of 16-bit Sensor Data Bus (Bayer, YUV, YCrCb, RGB)	LCD1_CLK	ALT3	I
CSI_DATA17	Data Sensor Signal, part of 16-bit Sensor Data Bus (Bayer, YUV, YCrCb, RGB)	LCD1_ENABLE	ALT3	I
CSI_DATA18	Data Sensor Signal, part of 16-bit Sensor Data Bus (Bayer, YUV, YCrCb, RGB)	LCD1_HSYNC	ALT3	I
CSI_DATA19	Data Sensor Signal, part of 16-bit Sensor Data Bus (Bayer, YUV, YCrCb, RGB)	LCD1_VSYNC	ALT3	I
CSI_DATA20	Data Sensor Signal, part of 16-bit Sensor Data Bus (Bayer, YUV, YCrCb, RGB)	LCD1_DATA00	ALT3	I

CSI_DATA23	Data Sensor Signal, part of 16-bit Sensor Data Bus (Bayer, YUV, YCrCb, RGB)	LCD1_DATA03	ALT3	I
CSI_FIELD	CSI Field Signal	LCD1_RESET	ALT3	I

Table continues on the next page...

**Table 13-5. CSI External Signals (continued)**

Signal	Description	Pad	Mode	Direction
CSI_HSYNC	Horizontal Sync (Blank Signal)	I2C3_SDA	ALT3	I
		LCD1_DATA05	ALT3	
CSI_MCLK	"CMOS Sensor Master Clock *Note: MCLK is provided by the CCM module directly, not from the CSI module itself"	I2C4_SDA	ALT3	O
		LCD1_DATA07	ALT3	
CSI_PIXCLK	Pixel Clock	I2C4_SCL	ALT3	I
		LCD1_DATA06	ALT3	
CSI_VSYNC	Vertical Sync (Start Of Frame)	I2C3_SCL	ALT3	I
		LCD1_DATA04	ALT3	

### 13.3.3 Clocks

The following table describes the clock sources for CSI. Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

**Table 13-6. CSI Clocks**

Clock name	Clock Root	Description
csi_hclk	MAIN_AXI_CLK_ROOT	Module clock
ipg_clk	MAIN_AXI_CLK_ROOT	Peripheral clock
ipg_clk_s	MAIN_AXI_CLK_ROOT	Peripheral access clock
ipg_clk_s_raw	MAIN_AXI_CLK_ROOT	Peripheral raw data clock

### 13.3.4 Principles of Operation

The information found here describes the modes of operation of the sensor interface.

The CSI is designed to support generic sensor interface timing as well as CCIR656 video interface timing. Traditional CMOS sensors typically use VSYNC (SOF), HSYNC (BLANK), and PIXCLK signals to output Bayer or YUV data. Smart CMOS sensors, that come with on-chip imaging processing, usually support video mode transfer. They use an embedded timing codec to replace the VSYNC and HSYNC signal. The timing codec is defined by the CCIR656 standard.

The CSI can support connection with the sensor as follows.

- To connect with one 8-bit sensor, the sensor data interface should connect to CSI\_DATA[9:2].

- To connect with one 10-bit sensor, the sensor data interface should connect to CSI\_DATA[9:0].
- To connect with one 16-bit sensor, the sensor data interface should connect to CSI\_DATA[15:0].
- To connect with two 8-bit sensors, the sensor data interfaces should connect to CSI\_DATA[7:0] and CSI\_DATA[15:8].

### 13.3.4.1 Data Transfer with the Embedded DMA Controllers

The CSI has two embedded DMA controllers, one for the receive FIFO and the other for the statistic FIFO. It supports 2D DMA transfer from the receive FIFO to the frame buffers in the external memory and linear DMA transfer from the statistic FIFO.

To transfer data from the Rx FIFO to the external memory, the user should set the start address in the frame buffer where the transferred data is stored, the parameters of the frame buffers, and the parameters of the image coming from the sensor. The user can have two frame buffers in the external memory. Each one will store a frame of image coming from the sensor. The embedded DMA controller will first write the frame buffer1 and then frame buffer2. These two frame buffers will be written by turns. The start address should be aligned in double words and set in the CSIDMASA-FB1 and CSIDMASA-FB2 registers. In the CSIFBUF\_PARA register, the user should set the stride of the frame buffer to show how many double words to skip before starting to write the next row of the image. In the CSIIMAG\_PARA register, the user should set the width and height of the image coming from the sensor. The RxFF\_LEVEL and DMA\_REQ\_EN\_RFF bits in CSICR3 registers also need to be set before the data transfer starts. When the number of the data in the Rx FIFO reaches the trigger level, a DMA request will be sent to the embedded DMA controller and the data will be read out from the Rx FIFO and written through AHB bus into the external frame buffers. The burst type of transfer can be INCR4, INCR8 and INCR16 by setting DMA\_BURST\_TYPE\_RFF bits in CSICR2 register. After all data in an image frame are transferred, the DMA\_TSF\_DONE\_FB1 or DMA\_TSF\_DONE\_FB2 bit will be set in

CSISR register and the interrupt can be triggered if the corresponding enable bit is set in CSICR1 register. The DMA\_REFLASH\_RFF bit in CSICR3 can be used to activate or restart the embedded DMA controller.

The RxFIFO has the overrun protection mechanism in case the RxFIFO is overrun during data transfer. If the RxFIFO is full and more data needs to be received during the data transfer, the RxFIFO will be overwritten continuously and all 128 words of data in the RxFIFO before overrun occurred will be discarded; the corresponding 128 words memory space in the frame buffer will keep the previous values.

To transfer data from the statistic FIFO to the external memory, the user should set the start address of the external memory where the transferred data is stored and the total transfer sizes. The start address and the transfer sizes are all aligned in double words and should be set in the CSIDMASA-STATFIFO and CSIDMATS-STATFIFO registers. The STATFF\_LEVEL and DMA\_REQ\_EN\_SFF bits in CSICR3 registers should also be set before the data transfer starts. When the number of the data in the STATFIFO reaches the trigger level, a dma request will be sent to the embedded DMA controller and the data will be read out from the STATFIFO and written through AHB bus into the external memory. The burst type of transfer can be INCR4, INCR8 and INCR16 by setting DMA\_BURST\_TYPE\_SFF bits in CSICR2 register. After all expected data (defined by the total transfer sizes) are transferred, the DMA\_TSF\_DONE\_SFF bit will be set in CSISR register and an interrupt can be triggered if the SFF\_DMA\_DONE\_INTEN is enabled in CSICR1 register. The DMA\_REFLASH\_SFF bit in CSICR3 can be used to activate or re-start the embedded DMA controller.

### 13.3.4.2 Gated Clock Mode

VSYNC, HSYNC, and PIXCLK signals are used in gated clock mode.

A frame starts with an active edge on VSYNC, then HSYNC asserts and holds for the entire line. The Pixel clock is valid as long as HSYNC is asserted. Data is latched at the active edge of the valid pixel clocks. HSYNC deasserts at the end of line. Pixel clocks then become invalid and CSI stops receiving data from the stream. For the next line the HSYNC timing repeats. For the next frame the VSYNC timing repeats.

### 13.3.4.3 Non-Gated Clock Mode

In non-gated clock mode, only the VSYNC and PIXCLK signals are used; the HSYNC signal is ignored.

**Figure 13-18. Non-Gated Clock Mode Timing Diagram**

The overall timing of non-gated mode is the same as the gated-clock mode, except for the HSYNC signal. HSYNC signal is ignored by the CSI. All incoming pixel clocks are valid and cause data to be latched into RxFIFO. The PIXCLK signal is inactive (states low) until valid data is ready to be transmitted over the bus.

Figure 13-18 shows the timing of a typical sensor. Other sensors may have the slightly different timing from that shown. The CSI can be programmed to support rising/falling-edge triggered VSYNC, active-high/low HSYNC, and rising/falling-edge triggered PIXCLK.

### 13.3.4.4 CCIR656 Interlace Mode

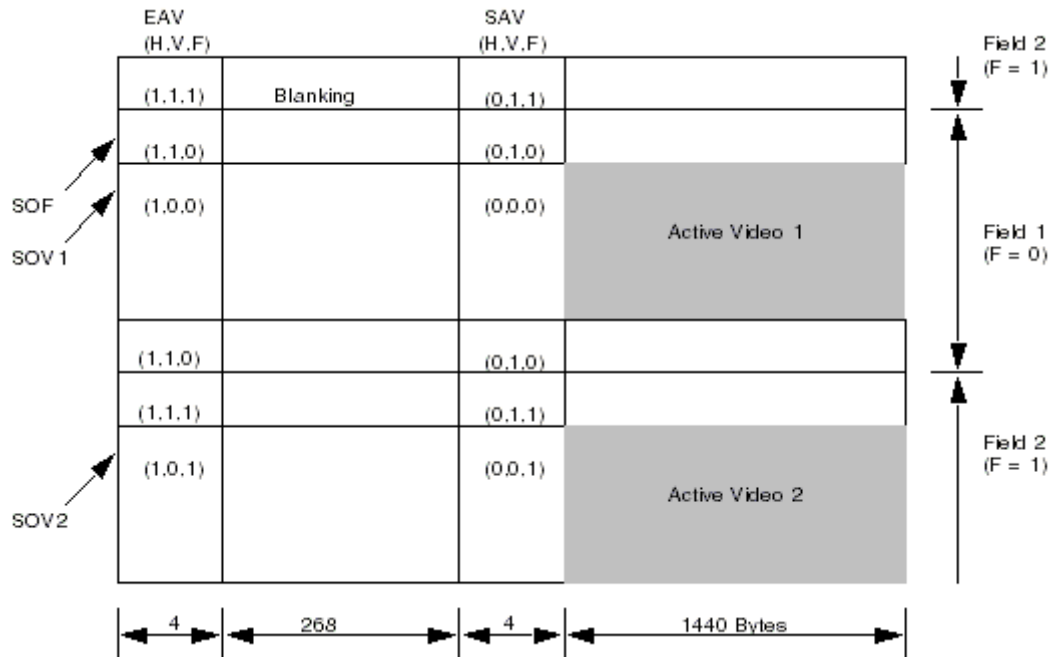

In CCIR656 mode, only the PIXCLK and CSI\_DATA[13:6] signals are used. The start of frame and blank signals are replaced by a timing codec which is embedded in the data stream. Each active line starts with an Start of Active Video (SAV) code and ends with an End of Active Video (EAV) code. In some cases, digital blanking is inserted in between EAV and SAV code. The CSI decodes and filters out the timing-coding from the data stream, recovering VSYNC and HSYNC signals for internal use, such as statistical block control. Data is forwarded to the data receive and packing block in a sequential manner without reordering—that is, field 1 followed by field 2. The fields must be reordered in software to get back the original image.

Change of Field (COF) interrupt is triggered upon every field change. The interrupt service routine reads the status register to check for the current field.

According to the CCIR656 specification, the image must be in 625/50 PAL or 525/60 NTSC format. In addition, the image is interlaced into odd and even fields with vertical and horizontal blank data being filled into certain lines. Data must be in YCbCr422 format, each pixel contains 2 bytes, either Y + Cr or Y + Cb. These requirements are set for TV systems. The CSI module supports PAL and NTSC format only.

Figure below describes the frame structure in PAL system, showing vertical and horizontal blanking.

**Figure 13-19. CCIR656 Interlace Mode (PAL)**

Figure below describes the general timing for a single line, showing SAV and EAV.

**Figure 13-20. CCIR656 General Line Timing**

The coding tables recommended by the CCIR656 specification are shown below. It is used in the CCIR656 mode to decode the video stream. An interrupt is generated for SOF, which is decoded from the embedded timing codec.

**Table 13-8. Coding for SAV and EAV**

Data Bit Number	1st Byte 0xFF	2nd Byte 0x00	3rd Byte 0x00	4th Byte 0xXY
7 (MSB)	1	0	0	1
6	1	0	0	F
5	1	0	0	V
4	1	0	0	H

*Table continues on the next page...*

**Table 13-8. Coding for SAV and EAV (continued)**

Data Bit Number	1st Byte 0xFF	2nd Byte 0x00	3rd Byte 0x00	4th Byte 0xXY
3	1	0	0	P3
2	1	0	0	P2
1	1	0	0	P1
0	1	0	0	P0

**Table 13-9. Codes with Protection bits for Error Detection/Correction**

F	V	H	P3	P2	P1	P0
0	0	0	0	0	0	0
0	0	1	1	1	0	1
0	1	0	1	0	1	1
0	1	1	0	1	1	0
1	0	0	0	1	1	1
1	0	1	1	0	1	0
1	1	0	1	1	0	0
1	1	1	0	0	0	1

**Table 13-10. Representations by F-Bit**

F-Bit	Representations
0	ODD FIELD (FIELD 1)
1	EVEN FIELD (FIELD 2)

### 13.3.4.5 CCIR656 Progressive Mode

For a CMOS camera system of VGA or CIF resolution, strict adherence to the interlace requirements stated in the CIR standard is not required.

The image is considered to have only 1 active field which is scanned in a progressive manner. This active field is regarded as field 1 and the F-bit in the timing codec is ignored by the decoder. Most sensors support CCIR timing in this mode (progressive) by default.

Figure below shows the typical flow of progressive mode.

**Figure 13-21. CCIR656 Progressive Mode (General Case)**

An interrupt is generated for SOF but not for COF. In the general case, when SOF information is retrieved from the embedded coding, it is known as internal VSYNC mode. In other cases, when the VSYNC signal is provided by the sensor, it is known as external VSYNC mode. The CSI can be operated in internal or external VSYNC mode.

### 13.3.4.6 Error Correction for CCIR656 Coding

According to the algorithm for CCIR coding, protection bits in the SAV and EAV are encoded in the way that allows a 1-bit error to be corrected, or a 2-bit error to be detected by the decoder. This feature is supported by the interlace mode CCIR decoder in CSI.

For the 1-bit error case, users can select the error to be corrected automatically, or simply shown as a status flag instead. For the 2-bit error case, because the decoder is unable to make a correction, the error would be shown as a status flag only.

An interrupt can be generated upon the detection of an error. This signal can be enabled or disabled without affecting the operation of the status bit.

## 13.3.5 Interrupt Generation

The information found here describes CSI events that generate interrupts.

### 13.3.5.1 Start Of Frame Interrupt (SOF\_INT)

The source of an SOF interrupt is dependent on the mode of operation.

In traditional mode, VSYNC signal is taken from sensor and SOF\_INT is generated at the rising or falling edge (programmable) of VSYNC.

In CCIR interlace mode, the SOF interrupt information is retrieved from the embedded coding and SOF\_INT is generated.

In CCIR progressive mode, there are two sources of an SOF interrupt:

- In *internal* VSYNC mode, SOF is retrieved from the embedded coding.
- In *external* VSYNC mode, VSYNC is taken from the sensor and SOF is generated at the rising edge of VSYNC.

### 13.3.5.2 End Of Frame Interrupt (EOF\_INT)

An EOF interrupt is generated when the frame ends and the complete frame data in RXFIFO is read.

The EOF event triggering works with the RX count register (CSIRXCNT). Software sets the RX count register to the frame size (in words). The CSI RX logic then counts the number of pixel data being received and compares it with the RX count. If the preset value is reached, an EOF interrupt is generated and the data in the RXFIFO are read. If a SOF event is detected before this happens, the EOF interrupt is not generated.

### 13.3.5.3 Change Of Field Interrupt (COF\_INT)

The Change of Field interrupt is only valid in CCIR Interlace mode. The COF interrupt is generated when the field toggles, either from field 1 to field 2, or field 2 to field 1.

Software should first check COF\_INT bit in the CSI Status Register (CSISTAT) before checking that F1\_INT or F2\_INT is turned on.

In PAL systems, the field changes at the beginning of the frame and coincides with SOF. For the first field, a COF interrupt is not generated, only an SOF. The COF interrupt is generated for the second field.

#### **13.3.5.4 CCIR Error Interrupt (ECC\_INT)**

The CCIR Error Interrupt is only valid for CCIR Interlace mode. An ECC interrupt is generated when an error is found on the SAV or EAV codes in the incoming stream. When this happens, the ECC\_INT status bit is set.

#### **13.3.5.5 RxFIFO Full Interrupt (RxFF\_INT)**

A RxFIFO full interrupt is generated when the number of data in RXFIFO reaches the water mark defined by RxFF\_LEVEL in CSICR3.

#### **13.3.5.6 Statistic FIFO Full Interrupt (STATFF\_INT)**

A StatFIFO full interrupt is generated when the number of data in STATFIFO reaches the water mark defined by STATFF\_LEVEL in CSICR3.

#### **13.3.5.7 RxFIFO Overrun Interrupt (RFF\_OR\_INT)**

A RxFIFO Overrun interrupt is generated when the RxFIFO has 128 words data and more data is being written in.

#### **13.3.5.8 Statistic FIFO Overrun Interrupt (SFF\_OR\_INT)**

A StatFIFO Overrun interrupt is generated when the STATFIFO has 64 words data and more data is being written in.

#### **13.3.5.9 Frame Buffer1 DMA Transfer Done Interrupt (DMA\_TSF\_DONE\_FB1)**

A DMA transfer done interrupt of frame buffer1 is generated when one frame of data are transferred from RxFIFO to the frame buffer1 in the external memory.

#### **13.3.5.10 Frame Buffer2 DMA Transfer Done Interrupt (DMA\_TSF\_DONE\_FB2)**

A DMA transfer done interrupt of frame buffer2 is generated when one frame of data are transferred from RxFIFO to the frame buffer2 in the external memory.

### 13.3.5.11 Statistic FIFO DMA Transfer Done Interrupt (DMA\_TSF\_DONE\_SFF)

A StatFIFO DMA transfer done interrupt is generated when all the data are transferred from StatFIFO to the external memory. The transfer size is defined in the STATFIFO DMA Transfer Size Register.

### 13.3.5.12 AHB Bus Response Error Interrupt (HRESP\_ERR\_INT)

An AHB Bus response error interrupt is generated when a bus error is detected.

## 13.3.6 Data Packing Style

Careful attention to endianness is needed given the different port sizes at different stages of the image capture path.

To enable flexible packing of image data before storage in the FIFOs, the CSI module can swap data fields by use of the PACK\_DIR and the SWAP16\_EN bit in CSI Control Register 1 (CSICR1).

The CSI module accepts 8-bit, 10-bit or 16-bit data from the sensor by configuring PIXEL\_BIT bit in CSI Control Register 1 (CSICR1) and TWO\_8BIT\_SENSOR bit in CSI Control Register3 (CSICR3). The input data is packed according to the setting of PACK\_DIR bit. The packed data is stored in the RX FIFO according to the setting of the SWAP16\_EN bit.

For 10-bit per pixel data format, each pixel is expanded to 16 bits by appending 6 zeros bits to the most significant bit. For 16-bit data format, the data path can be a combination by two 8-bit sensors. One sensor is connected to the CSI\_DATA[7:0]. The other sensor is connected to CSI\_DATA[15:8].

### 13.3.6.1 RX FIFO Path

#### 13.3.6.1.1 Bayer Data

Bayer data is a type of raw data from the image sensor. This byte-wide data must be converted to the RGB space or YUV space by software. The data path for Bayer data is from the CSI to memory. If the system is in little endian, then the PACK\_DIR bit should be set to 0. 8-bit data format from a sensor is packed to 64 bits as

P7.P6.P5.P4.P3.P2.P1.P0, where P0 is the pixel coming in time slot 0 (first data) and P3 is the pixel coming in time slot 3 (the last data in the 64-bit word). When the data is addressed as bytes by software, P0 is transferred first, P1 is transferred next, and so on. 10-bit data format is packed to 64 bits as 000000.P3.000000.P2.000000.P1.000000.P0, where P0 is the 10-bit data coming in time slot 0 (first pixel) and P3 is the 10-bit data coming in time slot 3 (fourth pixel). 16-bit data, from two sensors, is packed to 64 bits as P7.P6.P5.P4.P3.P2.P1.P0, where P0 and P1 are the two 8-bit data coming in time slot 0 (P0 is the first pixel of the sensor connected with CSI\_DATA[7:0] and P1 is the first pixel of the sensor connected with CSI\_DATA[15:8]). P2 and P3 are the two 8-bit data coming in time slot 1 (second pixels of the two sensors).

### 13.3.6.1.2 RGB565 Data

RGB565 data is processed data from the image sensor, which can be put directly into the display buffer. The data is 16 bits wide. The data path is from CSI to memory to the display controller. On the sensor side, data must be transmitted as P0 first, followed by P1, and so on. For each pixel, whether the MSB or LSB is sent first depends on the endianness of the sensor. Data is 16 bits wide with the MSB labeled RG, and the LSB labeled GB. P0 is represented as RG0 and GB0.

CSI receives data in one of the following sequence:

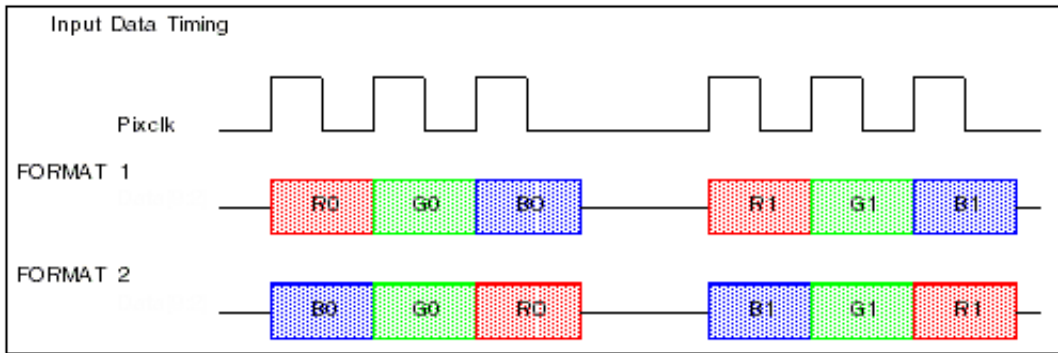

- RG0, GB0, RG1, GB1, while RG0 comes out at time slot 0 (first data), and GB1 comes out at time slot 3 (last data)
- GB0, RG0, GB1, RG1

Using the first sequence as an example, and assuming the system is running in little endian, the data is presented as:

- 8-bit data from sensor: RG0, GB0, RG1, GB1, ...
- 64-bit data before storage in the CSI RX FIFO (PACK\_DIR bit = 1):  
RG0GB0RG1GB1RG2GB2RG3GB3
- 64-bit data in CSI RX FIFO (SWAP16\_EN bit enabled):  
RG3GB3RG2GB2RG1GB1RG0GB0
- 64-bit transfer to system memory: RG3GB3RG2GB2RG1GB1RG0GB0
- 16-bit read by display controller: RG0GB0, RG1GB1

### 13.3.6.1.3 RGB888 Data

This is another kind of processed data from image sensor, which can be used for further image processing directly. Each of the data consist of 8-bit Red, 8-bit Green, and 8-bit Blue data. An example of timing scheme is shown in the figure below.

**Figure 13-22. Sample Timing Diagram for RGB888 8 bits/cycle Data**

An optional scheme to pack a dummy byte is provided. For every group of 3 bytes data, a dummy zero is packed to form a 32-bit word as shown in the figure below. The dummy zero can be packed at the LSB position or MSB position. Using RGB888A\_FORMAT\_SEL in CSI\_CSICR18[18] to determine to put the dummy bytes packed at LSB or MSB position.

### 13.3.6.2 STAT FIFO Path

Statistics only works for Bayer data in 8-bit per pixel format. It generates 16-bit statistical output from the 8-bit Bayer input (CSI\_DATA[13:6]). The outputs are Sum of Green (G), Sum of Red (R), Sum of Blue (B), and Auto Focus (F). Each output is 16-bits wide.

The settings of PACK\_DIR and SWAP16\_EN bits in the CSICR1 register have no effect on the input path. The PACK\_DIR only controls how the 16-bit stat output is packed into the 32-bit STAT FIFO.

When the PACK\_DIR bit = 1, the stat data is packed as:

First 32-bit: RG

Second 32-bit: BF

...

When the PACK\_DIR bit = 0, the stat data is packed as:

First 32-bit GR

Second 32-bit: FB

...

### 13.3.7 CSI Memory Map/Register Definition

All the 32-bit registers of the CSI module are summarized in the Memory Map below:

**CSI memory map**

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
3071_0000	CSI Control Register 1 (CSI_CSICR1)	32	R/W	4000_0800h	<a href="#">13.3.7.1/3716</a>
3071_0004	CSI Control Register 2 (CSI_CSICR2)	32	R/W	0000_0000h	<a href="#">13.3.7.2/3720</a>

### 13.3.7.1 CSI Control Register 1 (CSI\_CSICR1)

This register controls the sensor interface timing and interrupt generation. The interrupt enable bits in this register control the interrupt signals and the status bits. That means status bits will only function when the corresponding interrupt bits are enabled.

Address: 3071\_0000h base + 0h offset = 3071\_0000h

**CSI\_CSICR1 field descriptions**

Field	Description
31 SWAP16_EN	<p>SWAP 16-Bit Enable. This bit enables the swapping of 16-bit data. Data is packed from 8-bit or 10-bit to 32-bit first (according to the setting of PACK_DIR) and then swapped as 16-bit words before being put into the RX FIFO. The action of the bit only affects the RX FIFO and has no affect on the STAT FIFO.</p> <p><b>NOTE:</b> Example of swapping enabled: Data input to FIFO = 0x11223344 Data in RX FIFO = 0x 33441122</p> <p><b>NOTE:</b> Example of swapping disabled: Data input to FIFO = 0x11223344 Data in RX FIFO = 0x11223344</p>

Table continues on the next page...

## CSI\_CSICR1 field descriptions (continued)

Field	Description
	0 Disable swapping 1 Enable swapping
30 EXT_VSYNC	External VSYNC Enable. This bit controls the operational VSYNC mode. <b>NOTE:</b> This only works when the CSI is in CCIR progressive mode. 0 Internal VSYNC mode 1 External VSYNC mode
29 EOF_INT_EN	End-of-Frame Interrupt Enable. This bit enables and disables the EOF interrupt. 0 EOF interrupt is disabled. 1 EOF interrupt is generated when RX count value is reached.
28 PrP_IF_EN	CSI-PrP Interface Enable. This bit controls the CSI to PrP bus. When enabled the RxFIFO is detached from the AHB bus and connected to PrP. All CPU reads or DMA accesses to the RxFIFO register are ignored. All CSI interrupts are also masked. 0 CSI to PrP bus is disabled 1 CSI to PrP bus is enabled
27 VIDEO_MODE	Video mode select. This bit controls the video mode in CCIR mode and TV decoder input. 0 Progressive mode is selected 1 Interlace mode is selected
26 COF_INT_EN	Change Of Image Field (COF) Interrupt Enable. This bit enables the COF interrupt. This bit works only in CCIR interlace mode which is when CCIR_EN = 1 and CCIR_MODE = 1. 0 COF interrupt is disabled 1 COF interrupt is enabled
25 SF_OR_INTEN	STAT FIFO Overrun Interrupt Enable. This bit enables the STATFIFO overrun interrupt. 0 STATFIFO overrun interrupt is disabled 1 STATFIFO overrun interrupt is enabled
24 RF_OR_INTEN	RxFIFO Overrun Interrupt Enable. This bit enables the RX FIFO overrun interrupt. 0 RxFIFO overrun interrupt is disabled 1 RxFIFO overrun interrupt is enabled
23 -	This field is reserved. Reserved. This bit is reserved and should read 0.
22 SFF_DMA_DONE_INTEN	STATFIFO DMA Transfer Done Interrupt Enable. This bit enables the interrupt of STATFIFO DMA transfer done. 0 STATFIFO DMA Transfer Done interrupt disable 1 STATFIFO DMA Transfer Done interrupt enable
21 STATFF_INTEN	STATFIFO Full Interrupt Enable. This bit enables the STAT FIFO interrupt. 0 STATFIFO full interrupt disable 1 STATFIFO full interrupt enable
20 FB2_DMA_DONE_INTEN	Frame Buffer2 DMA Transfer Done Interrupt Enable. This bit enables the interrupt of Frame Buffer2 DMA transfer done.

Table continues on the next page...

## CSI\_CSICR1 field descriptions (continued)

Field	Description
	0 Frame Buffer2 DMA Transfer Done interrupt disable 1 Frame Buffer2 DMA Transfer Done interrupt enable
19 FB1_DMA_ DONE_INTEN	Frame Buffer1 DMA Transfer Done Interrupt Enable. This bit enables the interrupt of Frame Buffer1 DMA transfer done. 0 Frame Buffer1 DMA Transfer Done interrupt disable 1 Frame Buffer1 DMA Transfer Done interrupt enable
18 RXFF_INTEN	RxFIFO Full Interrupt Enable. This bit enables the RxFIFO full interrupt. 0 RxFIFO full interrupt disable 1 RxFIFO full interrupt enable
17 SOF_POL	SOF Interrupt Polarity. This bit controls the condition that generates an SOF interrupt. 0 SOF interrupt is generated on SOF falling edge 1 SOF interrupt is generated on SOF rising edge
16 SOF_INTEN	Start Of Frame (SOF) Interrupt Enable. This bit enables the SOF interrupt. 0 SOF interrupt disable 1 SOF interrupt enable
15–12 Reserved	This field is reserved. Reserved. This field is reserved.
11 HSYNC_POL	HSYNC Polarity Select. This bit controls the polarity of HSYNC. This bit only works in gated-clock-that is, GCLK_MODE = 1 and CCIR_EN = 0. 0 HSYNC is active low 1 HSYNC is active high
10 CCIR_EN	CCIR656 Interface Enable. This bit selects the type of interface used. When the CCIR656 timing decoder is enabled, it replaces the function of timing interface logic. 0 Traditional interface is selected. Timing interface logic is used to latch data. 1 CCIR656 interface is selected.
9 Reserved	This field is reserved. This field is reserved.
8 FCC	FIFO Clear Control. This bit determines how the RXFIFO and STATFIFO are cleared. When Synchronous FIFO clear is selected the RXFIFO and STATFIFO are cleared, and STAT block is reset, on every SOF. FIFOs and STAT block restarts immediately after reset. For information on the operation when Asynchronous FIFO clear is selected, refer to the descriptions for the CLR_RXFIFO and CLR_STATFIFO bits. 0 Asynchronous FIFO clear is selected. 1 Synchronous FIFO clear is selected.
7 PACK_DIR	Data Packing Direction. This bit Controls how 8-bit/10-bit image data is packed into 32-bit RX FIFO, and how 16-bit statistical data is packed into 32-bit STAT FIFO. 0 Pack from LSB first. For image data, 0x11, 0x22, 0x33, 0x44, it will appear as 0x44332211 in RX FIFO. For stat data, 0xAAAA, 0BBBB, it will appear as 0BBBBAAAA in STAT FIFO. 1 Pack from MSB first. For image data, 0x11, 0x22, 0x33, 0x44, it will appear as 0x11223344 in RX FIFO. For stat data, 0xAAAA, 0BBBB, it will appear as 0AAAABBBB in STAT FIFO.

Table continues on the next page...

## CSI\_CSICR1 field descriptions (continued)

Field	Description
6 CLR_STATFIFO	Asynchronous STATFIFO Clear. This bit clears the STATFIFO and Reset STAT block. This bit works only in async FIFO clear mode-that is, FCC = 0. Otherwise this bit is ignored. Writing 1 will clear STATFIFO and reset STAT block immediately, STATFIFO and STAT block then wait and restart after the arrival of next SOF. The bit is restored to 0 automatically after finish. Normally reads 0.
5 CLR_RXFIFO	Asynchronous RXFIFO Clear. This bit clears the RXFIFO. This bit works only in async FIFO clear mode-that is, FCC = 0. Otherwise this bit is ignored. Writing 1 clears the RXFIFO immediately, RXFIFO restarts immediately after that. The bit is restored to 0 automatically after finish. Normally reads 0.
4 GCLK_MODE	Gated Clock Mode Enable. Controls if CSI is working in gated or non-gated mode. This bit works only in traditional mode-that is, CCIR_EN = 0. Otherwise this bit is ignored. 0 Non-gated clock mode. All incoming pixel clocks are valid. HSYNC is ignored. 1 Gated clock mode. Pixel clock signal is valid only when HSYNC is active.
3 INV_DATA	Invert Data Input. This bit enables or disables internal inverters on the data lines. 0 CSI_D[7:0] data lines are directly applied to internal circuitry 1 CSI_D[7:0] data lines are inverted before applied to internal circuitry
2 INV_PCLK	Invert Pixel Clock Input. This bit determines if the Pixel Clock (CSI_PIXCLK) is inverted before it is applied to the CSI module. 0 CSI_PIXCLK is directly applied to internal circuitry 1 CSI_PIXCLK is inverted before applied to internal circuitry
1 REDGE	Valid Pixel Clock Edge Select. Selects which edge of the CSI_PIXCLK is used to latch the pixel data. 0 Pixel data is latched at the falling edge of CSI_PIXCLK 1 Pixel data is latched at the rising edge of CSI_PIXCLK
0 PIXEL_BIT	Pixel Bit. This bit indicates the bayer data width for each pixel. This bit should be configured before activating or re-starting the embedded DMA controller. 0 8-bit data for each pixel 1 10-bit data for each pixel

### 13.3.7.2 CSI Control Register 2 (CSI\_CSICR2)

This register provides the statistic block with data about which live view resolution is being used, and the starting sensor pixel of the Bayer pattern. It also contains the horizontal and vertical count used to determine the number of pixels to skip between the 64 x 64 blocks of statistics when generating statistics on live view image that are greater than 512 x 384.

Address: 3071\_0000h base + 4h offset = 3071\_0004h

**CSI\_CSICR2 field descriptions**

Field	Description
31–30 DMA_BURST_TYPE_RFF	Burst Type of DMA Transfer from RxFIFO. Selects the burst type of DMA transfer from RxFIFO. X0 INCR8 01 INCR4 11 INCR16
29–28 DMA_BURST_TYPE_SFF	Burst Type of DMA Transfer from STATFIFO. Selects the burst type of DMA transfer from STATFIFO. X0 INCR8 01 INCR4 11 INCR16

Table continues on the next page...

## CSI\_CSICR2 field descriptions (continued)

Field	Description
27 -	This field is reserved. Reserved. These bit is reserved and should read 0.
26 DRM	Double Resolution Mode. Controls size of statistics grid. 0 Stats grid of 8 x 6 1 Stats grid of 8 x 12
25–24 AFS	Auto Focus Spread. Selects which green pixels are used for auto-focus. 00 Abs Diff on consecutive green pixels 01 Abs Diff on every third green pixels 1x Abs Diff on every four green pixels
23 SCE	Skip Count Enable. Enables or disables the skip count feature. 0 Skip count disable 1 Skip count enable
22–21 -	This field is reserved. Reserved. These bits are reserved and should read 0.
20–19 BTS	Bayer Tile Start. Controls the Bayer pattern starting point. 00 GR 01 RG 10 BG 11 GB
18–16 LVRM	Live View Resolution Mode. Selects the grid size used for live view resolution. 0 512 x 384 1 448 x 336 2 384 x 288 3 384 x 256 4 320 x 240 5 288 x 216 6 400 x 300
15–8 VSC	Vertical Skip Count. Contains the number of rows to skip. SCE must be 1, otherwise VSC is ignored. 0-255 Number of rows to skip minus 1
HSC	Horizontal Skip Count. Contains the number of pixels to skip. SCE must be 1, otherwise HSC is ignored. 0-255 Number of pixels to skip minus 1

### 13.3.7.3 CSI Control Register 3 (CSI\_CSICR3)

This read/write register acts as an extension of the functionality of the CSI Control register 1, adding additional control and features.

Address: 3071\_0000h base + 8h offset = 3071\_0008h

#### CSI\_CSICR3 field descriptions

Field	Description
31–16 FRMCNT	Frame Counter. This is a 16-bit Frame Counter (Wraps around automatically after reaching the maximum)
15 FRMCNT_RST	Frame Count Reset. Resets the Frame Counter. (Cleared automatically after reset is done) 0 Do not reset 1 Reset frame counter immediately
14 DMA_REFLASH_RFF	Reflash DMA Controller for RxFIFO. This bit reflash the embedded DMA controller for RxFIFO. It should be reflash before the embedded DMA controller starts to work. (Cleared automatically after reflash is done) 0 No reflash 1 Reflash the embedded DMA controller
13 DMA_REFLASH_SFF	Reflash DMA Controller for STATFIFO. This bit reflash the embedded DMA controller for STATFIFO. It should be reflash before the embedded DMA controller starts to work. (Cleared automatically after reflash is done) 0 No reflash 1 Reflash the embedded DMA controller

Table continues on the next page...

## CSI\_CSICR3 field descriptions (continued)

Field	Description
12 DMA_REQ_EN_ RFF	DMA Request Enable for RxFIFO. This bit enables the dma request from RxFIFO to the embedded DMA controller.  0 Disable the dma request 1 Enable the dma request
11 DMA_REQ_EN_ SFF	DMA Request Enable for STATFIFO. This bit enables the dma request from STATFIFO to the embedded DMA controller.  0 Disable the dma request 1 Enable the dma request
10–8 STATFF_LEVEL	STATFIFO Full Level. When the number of data in STATFIFO reach this level, STATFIFO full interrupt is generated, or STATFIFO DMA request is sent.  000 4 Double words 001 8 Double words 010 12 Double words 011 16 Double words 100 24 Double words 101 32 Double words 110 48 Double words 111 64 Double words
7 HRESP_ERR_ EN	Hresponse Error Enable. This bit enables the hresponse error interrupt.  0 Disable hresponse error interrupt 1 Enable hresponse error interrupt
6–4 RxFF_LEVEL	<b>RxFIFO Full Level.</b> When the number of data in RxFIFO reaches this level, a RxFIFO full interrupt is generated, or an RxFIFO DMA request is sent.  000 4 Double words 001 8 Double words 010 16 Double words 011 24 Double words 100 32 Double words 101 48 Double words 110 64 Double words 111 96 Double words
3 TWO_8BIT_ SENSOR	Two 8-bit Sensor Mode. This bit indicates one 16-bit sensor or two 8-bit sensors are connected to the 16-bit data ports. This bit should be set if there is one 16-bit sensor or two 8-bit sensors are connected. This bit should be configured before activating or restarting the embedded DMA controller.  0 Only one sensor is connected. 1 Two 8-bit sensors are connected or one 16-bit sensor is connected.
2 ZERO_PACK_ EN	Dummy Zero Packing Enable. This bit causes a dummy zero to be packed with every 3 incoming bytes, forming a 32-bit word. The dummy zero is always packed to the LSB position. This packing function is only available in 8-bit/pixel mode.  0 Zero packing disabled 1 Zero packing enabled

Table continues on the next page...

### CSI\_CSICR3 field descriptions (continued)

Field	Description
1 ECC_INT_EN	<p>Error Detection Interrupt Enable. This bit enables and disables the error detection interrupt. This feature only works in CCIR interlace mode.</p> <p>0 No interrupt is generated when error is detected. Only the status bit ECC_INT is set. 1 Interrupt is generated when error is detected.</p>
0 ECC_AUTO_EN	<p>Automatic Error Correction Enable. This bit enables and disables the automatic error correction. If an error occurs and error correction is disabled only the ECC_INT status bit is set. This feature only works in CCIR interlace mode.</p> <p>0 Auto Error correction is disabled. 1 Auto Error correction is enabled.</p>

### 13.3.7.4 CSI Statistic FIFO Register (CSI\_CSISTATFIFO)

The StatFIFO is a read-only register containing statistic data from the sensor. Writing to this register has no effect.

Address: 3071\_0000h base + Ch offset = 3071\_000Ch

### CSI\_CSISTATFIFO field descriptions

Field	Description
STAT	Static data from sensor

### 13.3.7.5 CSI RX FIFO Register (CSI\_CSIRFIFO)

This read-only register contains received image data. Writing to this register has no effect.

Address: 3071\_0000h base + 10h offset = 3071\_0010h

### CSI\_CSIRFIFO field descriptions

Field	Description
IMAGE	Received image data

#### 13.3.7.6 CSI RX Count Register (CSI\_CSIRXCNT)

This register works for EOF interrupt generation. It should be set to the number of words to receive that would generate an EOF interrupt.

There is an internal counter that counts the number of words read from the RX FIFO. Whenever the RX FIFO is being read, by either the CPU or the embedded DMA controller, the counter value is updated and compared with this register. If the values match, then an EOF interrupt is triggered.

Address: 3071\_0000h base + 14h offset = 3071\_0014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### CSI\_CSIRXCNT field descriptions

Field	Description
31–22 -	This field is reserved. Reserved. These bits are reserved and should read 0.
RXCNT	RxFIFO Count. This 22-bit counter for RxFIFO is updated each time the RxFIFO is read by CPU or DMA. This counter should be set to the expected number of words to receive that would generate an EOF interrupt.

### 13.3.7.7 CSI Status Register (CSI\_CSISR)

This read/write register shows sensor interface status, and which kind of interrupt is being generated. The corresponding interrupt bits must be set for the status bit to function. Status bits should function normally even if the corresponding interrupt enable bits are not enabled.

Address: 3071\_0000h base + 18h offset = 3071\_0018h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R		-		BASEADDR_CHHANGE_ERROR	DMA_FIELD0_DONE	DMA_FIELD1_DONE	SF_OR_INT	RF_OR_INT	Reserved	DMA_TSF_DONE_SFF	STATFF_INT	DMA_TSF_DONE_FB2	DMA_TSF_DONE_FB1	RxFF_INT	EOF_INT	SOF_INT
W		-

W																
Reset	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**CSI\_CSISR field descriptions**

Field	Description
31–29 -	Reserved. These bits are reserved and should read 0.
28 BASEADDR_CHHANGE_ERROR	When using base address switching enable, this bit will be 1 when switching occur before DMA complete. This bit will be clear by writing 1. When this interrupt happens, follow the steps listed below. 1. Unassert the CSI enable, CSIx_CSICR18 bit31, 2. Reflash the DMA, assert the CSIX_CSICR3 bit 14, 3. Assert the CSI enable, CSIx_CSICR18 bit31.
27 DMA_FIELD0_DONE	When DMA field 0 is complete, this bit will be set to 1 (clear by writing 1).

Table continues on the next page...

## CSI\_CSISR field descriptions (continued)

Field	Description
26 DMA_FIELD1_ DONE	When DMA field 0 is complete, this bit will be set to 1 (clear by writing 1).
25 SF_OR_INT	STATFIFO Overrun Interrupt Status. Indicates the overflow status of the STATFIFO register. (Cleared by writing 1)  0 STATFIFO has not overflowed. 1 STATFIFO has overflowed.
24 RF_OR_INT	RxFIFO Overrun Interrupt Status. Indicates the overflow status of the RxFIFO register. (Cleared by writing 1)  0 RxFIFO has not overflowed. 1 RxFIFO has overflowed.
23 -	This field is reserved. Reserved. This bit is reserved and should read 0.
22 DMA_TSF_ DONE_SFF	DMA Transfer Done from StatFIFO. Indicates that the dma transfer from StatFIFO is completed. It can trigger an interrupt if the corresponding enable bit is set in CSICR1. This bit can be cleared by writing 1 or reflashing the StatFIFO dma controller in CSICR3. (Cleared by writing 1)  0 DMA transfer is not completed. 1 DMA transfer is completed.
21 STATFF_INT	STATFIFO Full Interrupt Status. Indicates the number of data in the STATFIFO reaches the trigger level. (this bit is cleared automatically by reading the STATFIFO)  0 STATFIFO is not full. 1 STATFIFO is full.
20 DMA_TSF_ DONE_FB2	DMA Transfer Done in Frame Buffer2. Indicates that the DMA transfer from RxFIFO to Frame Buffer2 is completed. It can trigger an interrupt if the corresponding enable bit is set in CSICR1. This bit can be cleared by by writing 1 or reflashing the RxFIFO dma controller in CSICR3. (Cleared by writing 1)  0 DMA transfer is not completed. 1 DMA transfer is completed.
19 DMA_TSF_ DONE_FB1	DMA Transfer Done in Frame Buffer1. Indicates that the DMA transfer from RxFIFO to Frame Buffer1 is completed. It can trigger an interrupt if the corresponding enable bit is set in CSICR1. This bit can be cleared by by writing 1 or reflashing the RxFIFO dma controller in CSICR3. (Cleared by writing 1)  0 DMA transfer is not completed. 1 DMA transfer is completed.
18 RxFF_INT	RxFIFO Full Interrupt Status. Indicates the number of data in the RxFIFO reaches the trigger level. (this bit is cleared automatically by reading the RxFIFO)  0 RxFIFO is not full. 1 RxFIFO is full.
17 EOF_INT	End of Frame (EOF) Interrupt Status. Indicates when EOF is detected. (Cleared by writing 1)  0 EOF is not detected. 1 EOF is detected.
16 SOF_INT	Start of Frame Interrupt Status. Indicates when SOF is detected. (Cleared by writing 1)

*Table continues on the next page...*

## CSI\_CSISR field descriptions (continued)

Field	Description
	0 SOF is not detected. 1 SOF is detected.
15 F2_INT	CCIR Field 2 Interrupt Status. Indicates the presence of field 2 of video in CCIR mode. (Cleared automatically when current field does not match)  <b>NOTE:</b> Only works in CCIR Interlace mode.  0 Field 2 of video is not detected 1 Field 2 of video is about to start
14 F1_INT	CCIR Field 1 Interrupt Status. Indicates the presence of field 1 of video in CCIR mode. (Cleared automatically when current field does not match)  <b>NOTE:</b> Only works in CCIR Interlace mode.  0 Field 1 of video is not detected. 1 Field 1 of video is about to start.
13 COF_INT	Change Of Field Interrupt Status. Indicates that a change of the video field has been detected. Only works in CCIR Interlace mode. Software should read this bit first and then dispatch the new field from F1_INT and F2_INT. (Cleared by writing 1)  0 Video field has no change. 1 Change of video field is detected.
12–8 -	This field is reserved. Reserved. These bits are reserved and should read 0.
7 HRESP_ERR_INT	Hresponse Error Interrupt Status. Indicates that a hresponse error has been detected. (Cleared by writing 1)  0 No hresponse error. 1 Hresponse error is detected.
6–2 -	This field is reserved. Reserved. These bits are reserved and should read 0.
1 ECC_INT	CCIR Error Interrupt. This bit indicates an error has occurred. This only works in CCIR Interlace mode. (Cleared by writing 1)  0 No error detected 1 Error is detected in CCIR coding
0 DRDY	RXFIFO Data Ready. Indicates the presence of data that is ready for transfer in the RxFIFO. (Cleared automatically by reading FIFO)  0 No data (word) is ready 1 At least 1 datum (word) is ready in RXFIFO.

### 13.3.7.8 CSI DMA Start Address Register - for STATFIFO (CSI\_CSIDMASA\_STATFIFO)

This register provides the start address for the embedded DMA controller of STATFIFO. The embedded DMA controller will read data from STATFIFO and write it to the external memory from the start address. This register should be configured before activating or restarting the embedded DMA controller.

Address: 3071\_0000h base + 20h offset = 3071\_0020h

Bit	31	30	29	28	27	26	25	24		23	22	21	20	19	18	17	16

W	DMA_START_ADDR_SFF															Reserved	
Reset	0	0	0	0	0	0	0	0		0	0	0	0	0	0	0	0

#### CSI\_CSIDMASA\_STATFIFO field descriptions

Field	Description
31–2 DMA_START_ADDR_SFF	DMA Start Address for STATFIFO. Indicates the start address to write data. The embedded DMA controller will read data from STATFIFO and write it from this address through AHB bus. The address should be double words aligned.
-	This field is reserved. Reserved. These bits are reserved and should read 0.

### 13.3.7.9 CSI DMA Transfer Size Register - for STATFIFO (CSI\_CSIDMATS\_STATFIFO)

This register provides the total transfer size for the embedded DMA controller of STATFIFO. This register should be configured before activating or restarting the embedded DMA controller.

Address: 3071\_0000h base + 24h offset = 3071\_0024h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16		15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**CSI\_CSIDMATS\_STATFIFO field descriptions**

Field	Description
DMA_TSF_SIZE_SFF	DMA Transfer Size for STATFIFO. Indicates how many words to be transferred by the embedded DMA controller. The size should be double words aligned.

**13.3.7.10 CSI DMA Start Address Register - for Frame Buffer1 (CSI\_CSIDMASA\_FB1)**

This register provides the start address in the frame buffer1 for the embedded DMA controller of RxFIFO. The embedded DMA controller will read data from RxFIFO and write it to the frame buffer1 from the start address. This register should be configured before activating or restarting the embedded DMA controller.

Address: 3071\_0000h base + 28h offset = 3071\_0028h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

**CSI\_CSIDMASA\_FB1 field descriptions**

Field	Description
31–2 DMA_START_ADDR_FB1	DMA Start Address in Frame Buffer1. Indicates the start address to write data. The embedded DMA controller will read data from RxFIFO and write it from this address through AHB bus. The address should be double words aligned.
-	This field is reserved. Reserved. These bits are reserved and should read 0.

### 13.3.7.11 CSI DMA Transfer Size Register - for Frame Buffer2 (CSI\_CSIDMASA\_FB2)

This register provides the start address in the frame buffer2 for the embedded DMA controller of RxFIFO. The embedded DMA controller will read data from RxFIFO and write it to the frame buffer2 from the start address. This register should be configured before activating or restarting the embedded DMA controller.

Address: 3071\_0000h base + 2Ch offset = 3071\_002Ch

#### CSI\_CSIDMASA\_FB2 field descriptions

Field	Description
31–2 DMA_START_ADDR_FB2	DMA Start Address in Frame Buffer2. Indicates the start address to write data. The embedded DMA controller will read data from RxFIFO and write it from this address through AHB bus. The address should be double words aligned.
-	This field is reserved. Reserved. These bits are reserved and should read 0.

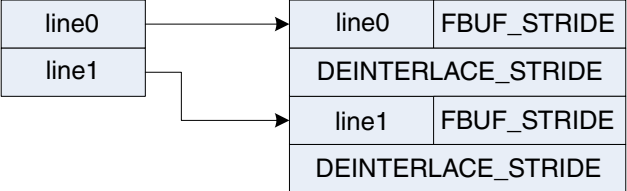

### 13.3.7.12 CSI Frame Buffer Parameter Register (CSI\_CSIFBUF\_PARA)

This register provides the stride of the frame buffer to show how many words to skip before starting to write the next row of the image. The width of the frame buffer minus the width of the image is the stride. This register should be configured before activating or restarting the embedded DMA controller.

Address: 3071\_0000h base + 30h offset = 3071\_0030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16		15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### CSI\_CSIFBUF\_PARA field descriptions

Field	Description
31–16 DEINTERLACE_STRIDE	<p>DEINTERLACE_STRIDE is only used in the deinterlace mode. If line stride feature is supported in deinterlace mode, FBUF_STRIDE and DEINTERLACE_STRIDE need to be configured at the same time. DEINTERLACE_STRIDE is configured the same as line width. In normal line stride feature, only FBUF_STRIDE needs to be configured.</p> 
FBUF_STRIDE	<p>Frame Buffer Parameter. Indicates the stride of the frame buffer. The width of the frame buffer(in double words) minus the width of the image(in double words) is the stride. The stride should be double words aligned. The embedded DMA controller will skip the stride before starting to write the next row of the image.</p>

### 13.3.7.13 CSI Image Parameter Register (CSI\_CSIIIMAG\_PARA)

This register provides the width and the height of the image from the sensor. The width and height should be aligned in pixel. The width of the image multiplied by the height is the total pixel size that will be transferred in a frame by the embedded DMA controller. This register should be configured before activating or restarting the embedded DMA controller.

Address: 3071\_0000h base + 34h offset = 3071\_0034h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## CSI\_CSICR18 field descriptions

Field	Description
31 CSI_ENABLE	CSI global enable signal. Only when this bit is 1, CSI can start to receive the data and store to memory.
30–25 MIPI_DATA_ FORMAT	Image Data Format Generic Short Packet: 0x08 ~ 0x0F Embedded 8-bit non Image: 0x12  YUV420 (8-bit)           0x18 YUV420 (10-bit)        0x19 YUV420 (8-bit legacy) 0x1A YUV420 (8-bit CSPS) 0x1C YUV420 (10-bit CSPS) 0x1D YUV422 (8-bit)         0x1E YUV422 (10-bit)        0x1F RGB444                 0x20 (Not support) RGB555                 0x21 (Not support) RGB565                 0x22 RGB666                 0x23 RGB888                 0x24 RAW6                    0x28 RAW7                    0x29 RAW8                    0x2A RAW10                   0x2B RAW12                   0x2C RAW14                   0x2D User defined 1         0x30 User defined 2         0x31 User defined 3         0x32 User defined 4         0x33 User defined 5         0x34 User defined 6         0x35 User defined 7         0x36 User defined 8         0x37
24 LINE_STRIDE_ EN	When the line width are not the multiple of the burst length, assert this bit.
23 -	Reserved
22 DATA_FROM_ MIPI	0 Data from parallel sensor 1 Data from MIPI
21 MIPI_YU_SWAP	It only works in MIPI CSI YUV422 double component mode.
20 MIPI_DOUBLE_ CMPNT	Double component per clock cycle in YUV422 formats. 0 Single component per clock cycle

*Table continues on the next page...*

## CSI\_CSICR18 field descriptions (continued)

Field	Description
	(half pixel per clock cycle) 1 Double component per clock cycle (a pixel per clock cycle)
19–18 MASK_OPTION	These bits used to choose the method to mask the CSI input. 00 Writing to memory from first completely frame, when using this option, the CSI_ENABLE should be 1. 01 Writing to memory when CSI_ENABLE is 1. 02 Writing to memory from second completely frame, when using this option, the CSI_ENABLE should be 1. 03 Writing to memory when data comes in, not matter the CSI_ENABLE is 1 or 0.
17–16 CSI_LCDIF_ BUFFER_LINES	The number of lines are used in handshake mode with LCDIF. 00 4 lines 01 8 lines 02 16 lines 03 16 lines
15–12 AHB_HPROT	Hprot value in AHB bus protocol.
11 -	This field is reserved.
10 RGB888A_ FORMAT_SEL	Output is 32-bit format. 0 {8'h0, data[23:0]} 1 {data[23:0], 8'h0}
9 BASEADDR_ CHANGE_ ERROR_IE	Base address change error interrupt enable signal.
8 LAST_DMA_ REQ_SEL	Choosing the last DMA request condition. 0 fifo_full_level 1 hburst_length
7 DMA_FIELD1_ DONE_IE	When in interlace mode, field 1 done interrupt enable. 0 Interrupt disabled 1 Interrupt enabled
6 FIELD0_DONE_ IE	In interlace mode, field 0 means interrupt enabled. 0 Interrupt disabled 1 Interrupt enabled
5 BASEADDR_ SWITCH_SEL	CSI 2 base addresses switching method. When using this bit, BASEADDR_SWITCH_EN is 1. 0 Switching base address at the edge of the vsync 1 Switching base address at the edge of the first data of each frame
4 BASEADDR_ SWITCH_EN	When this bit is enabled, CSI DMA will switch the base address according to BASEADDR_SWITCH_SEL rather than atomically by DMA completed.

*Table continues on the next page...*

## CSI\_CSICR18 field descriptions (continued)

Field	Description
3 PARALLEL24_ EN	When input is parallel rgb888/yuv444 24bit, this bit can be enabled.
2 DEINTERLACE_ EN	This bit is used to select the output method When input is standard CCIR656 video. 0 Deinterlace disabled 1 Deinterlace enabled
-	This field is reserved. Reserved.

## 13.4 MIPI DSI Host Controller (MIPI\_DSI)

### 13.4.1 Overview

#### 13.4.1.1 Key features

The following list summarizes the key features of the MIPI DSI:

- Complies to MIPI DSI Standard Specification V1.01r11
  - Maximum resolution ranges up to SXGA+(1400 x 11050 @ 60 Hz, 24 bpp)
    - It should be decided on bandwidth between input clock (video clock) and output clock (D-PHY HS clock).
  - Supports 1, 2 data lanes
  - Supports pixel format: 16 bpp, 18 bpp packed, 18 bpp loosely packed (3 byte format), and 24bpp
- Interfaces
  - Complies with Protocol-to-PHY Interface (PPI) in 1.0 Gbps / 1.5 Gbps MIPI D-PHY
  - Supports RGB Interface for Video Image Input from general display controller
  - Supports S-i80 (Synchronous i80) Interface for Command Mode Image input from display controller
  - Supports PMS control interface for PLL to configure byte clock frequency
  - Supports Prescaler to generate escape clock from byte clock

## 13.4.1.2 Block diagram

## 13.4.2 External Signals

The following table describes the external signals of MIPI DSI:

**Table 13-11. MIPI DSI External Signals**

Signal	Description	Pad	Mode	Direction
MIPI_DSI_CLK_N	D-PHY Negative D-Phy differential clock line Receiver input	MIPI_DSI_CLK_N	No muxing	I
MIPI_DSI_CLK_P	D-PHY Positive D-Phy differential clock line Receiver input	MIPI_DSI_CLK_P	No muxing	I
MIPI_DSI_D0_N	D-PHY Negative D-Phy differential data line Receiver input	MIPI_DSI_D0_N	No muxing	I
MIPI_DSI_D0_P	D-PHY Positive D-Phy differential data line Receiver input	MIPI_DSI_D0_P	No muxing	I
MIPI_DSI_D1_N	D-PHY Negative D-Phy differential data line Receiver input	MIPI_DSI_D1_N	No muxing	I
MIPI_DSI_D1_P	D-PHY Positive D-Phy differential data line Receiver input	MIPI_DSI_D1_P	No muxing	I

## 13.4.3 Functional Description

### 13.4.3.1 Total system block diagram

**Figure 13-24. MIPI DSI Master System Block Diagram**

### 13.4.3.2 MIPI DSI master and D-PHY I/F block diagram

Figure 13-25. PPI I/F block diagram

### 13.4.3.3 MIPI DSI master block diagram

Figure 13-26. MIPI DSI Master Module Block Diagram

### 13.4.3.4 Internal primary FIFOs

The following table describes configurable-sized primary FIFOs.

Table 13-12. Internal Primary FIFO List

Port	FIFO Type	Size	Description
Main display for RGB I/F and S-i80 I/F	Packet Header FIFO	3 Bytes X 128 depth	Packet header FIFO for main display
	Payload FIFO	4 Bytes X 2048 depth	Payload FIFO for main display image

Table continues on the next page...

**Table 13-12. Internal Primary FIFO List (continued)**

Port	FIFO Type	Size	Description
			(SRAM used)
Sub display for S-i80 I/F image data	Packet Header FIFO	3 Bytes X 4 depth	Packet header FIFO for S-i80 I/F sub display
	Payload FIFO	4 Bytes X 512 depth	Payload FIFO for S-i80 I/F sub display image (SRAM used)
Command for S-i80 I/F command	Packet Header FIFO	3 Bytes X 16 depth	Packet header FIFO for S-i80 I/F command packet
	Payload FIFO	4 Bytes X 16 depth	Payload FIFO for S-i80 I/F command long packet payload

### 13.4.3.5 Packet header arbitration

There are four-packet headers FIFOs for Tx, namely, main display, sub display, S-i80 INTERFACE command, and SFR FIFO. The main and sub display FIFO packet headers contain the image data, while the S-i80 INTERFACE command FIFO packet header contains the command packets. On the other hand, the SFR FIFO packet header contains command packets, sub display image data (in Video mode), and so on.

The packet header arbiter has a “Fixed priority” algorithm. Priority order is fixed as main display, sub display, S-i80 INTERFACE command, and SFR FIFO packet header.

In the Video mode, sub display and S-i80 INTERFACE command FIFO are not used. The SFR FIFO packet header checks if the main display FIFO is empty (no request) in not-active image region and then sends its request.

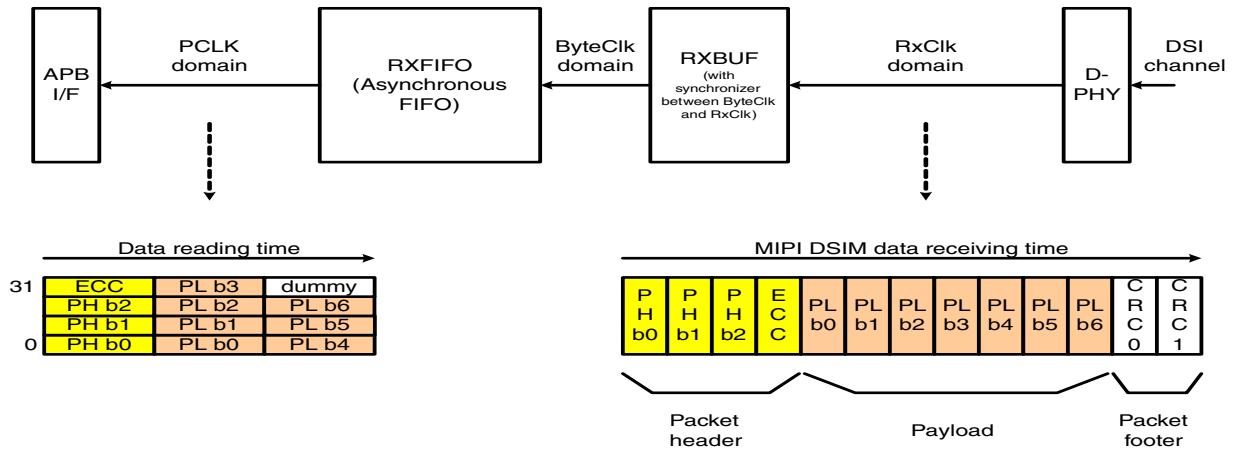

### 13.4.3.6 RxFIFO structure

To read the packets received via low power data receiving mode, RxFIFO acts like an SFR. RxFIFO is an asynchronous FIFO with ByteClk and PCLK domains as input clock and output clock domains respectively. The Rx data is synchronized to RxClk. RXBUF has four Rx Byte buffers for aligning byte to word.

The packet headers of all the packets stored in RXFIFO are word-aligned, that is, the first byte of a packet is always stored in LSB. For example, if a long packet has 7-byte payload, the last byte is filled with dummy byte and the next packet is stored in the next word, as shown in the following figure.

**NOTE**

CRC data is not stored in RXFIFO.

**Figure 13-27. Rx Data Word Alignment**

**13.4.3.7 Interfaces and protocol**

Display Controller-to-DSI Conceptual Signal Converting Diagram in Video Mode.

Figure 13-28. Signal Converting Diagram in Video Mode

### 13.4.3.8 Interface timing and protocol

#### 13.4.3.8.1 Display controller interface

MIPI DSI Master has two-display controller interfaces, namely, RGB INTERFACE for main display and CPU INTERFACE (S-i80 INTERFACE) for main/ sub display. The Video mode uses RGB INTERFACE while the Command mode uses CPU INTERFACE.

The RGB image data is loaded on the data bus of RGB INTERFACE and S-i80 INTERFACE with the same order: RGB\_VD[23:0] or SYS\_VDOOUT[23:0] is {R[7:0],G[7:0],B[7:0]}. Each byte aligns to the most significant bit. For instance, in the 12-bit mode, only three 4-bit values are valid as R, G, and B each, that is, data[23:20], data[15:12], and data[7:4]. The DSIM ignores rest of the bits.

### 13.4.3.8.2 RGB interface

Vsync, Hsync, and VDEN are active high signals. Among the three signals, Vsync and Hsync are pulse types that spend several video clocks. RGB\_VD[23:0] is {R[7:0], G[7:0], B[7:0]}. All sync signals are synchronized to the rising edge of RGB\_VCLK. The display controller sends minimum one horizontal line length of Vsync pulse, V back porch, and V front porch. Hsync pulse width should be longer than 1-byte clock cycle.

#### 13.4.3.8.2.1 HSA disable mode

HSA mode specifies the Horizontal Sync Pulse area disable mode.

**Figure 13-29. Block Timing Diagram of HSA Disable Mode (HSA Mode Reset : DSIM\_CONFIG[20] = 0)**

**Figure 13-30. Block Timing Diagram of HSA Disable Mode (HSA Mode Reset : DSIM\_CONFIG[20] = 1)**

### 13.4.3.8.2.2 HBP disable mode

This is optional spec what is used only burst mode. HBP mode is Horizontal Back Porch disable mode.

**Figure 13-31. Block Timing Diagram of HBP Disable Mode (HBP Mode Reset : DSIM\_CONFIG[21] = 0)**

**Figure 13-32. Block Timing Diagram of HBP Disable Mode (HBP Mode Set : DSIM\_CONFIG[21] = 1)**

### 13.4.3.8.2.3 HFP disable mode

This is optional spec what is used only burst mode. HFP mode is Horizontal Front Porch disable mode.

**Figure 13-33. Block Timing Diagram of HFP Disable Mode (HFP Mode Set : DSIM\_CONFIG[22] = 1)**

#### 13.4.3.8.2.4 HSE disable mode

HSE mode is Horizontal Sync End packet enable mode in Vsync pulse or Vporch area.

**Figure 13-34. Block Timing Diagram of HSE Disable Mode (HSE Mode Reset : DSIM\_CONFIG[23] = 0)**

**Figure 13-35. Block Timing Diagram of HSE Disable Mode (HSE Mode Reset : DSIM\_CONFIG[23] = 1)**

### 13.4.3.8.2.5 Transfer general data in video mode

**Figure 13-36. Stable VFP Area Before Command Transfer Allowing Area**

MIPI DSIM Converts RGB Interface to Video Mode.

Vsync and Hsync packets are extremely important to protect image in Video mode. MIPI DSIM allows several lines in VFP area to transfer general data transfer. As shown in the figure above, the vertical front porch is divided into three areas, namely stable VFP area, command allowed area, and command masked area.

The register configures stable VFP area. Configuration boundary is 11'h000 ~ 11'h7FFF in DSIM\_MVPORCH.

The register also configures the command allowed area. Configuration boundary is 4'h0 ~ 4'hF in DSIM\_MVPORCH. Only this area is allowed to start "command transfer" through HS mode or LPDT. In LPDT, data transferring takes a long time to complete (approximately hundreds of microseconds or more). In this time, Hsync packet does not arrive due to LPDT long packet. MIPI DSIM comprises of big size FIFO for lost Hsync packet. After LPDT, MIPI DSIM transfers these Hsync packets immediately through HS mode.

To protect Vsync, command masked area is masked area. This area is calculated using LPDT bandwidth. For example, if EscClk is 10 MHz, the maximum long packet payload size is 1 KB and LPDT, LPDT transferring time is 824  $\mu$ s (packet size: 1030 byte, LPDT maximum bandwidth: 10Mbps). If one line time is 20  $\mu$ s, the line timing violation occurs in 42 lines. Therefore, command masked area is larger than  $42 + \alpha$ . This ' $\alpha$ ' is transferring time of the violated Hsync packets.

Display controller should be configured in such a way that VFP lines are sum of stable VFP, command allowed area, and command masked area.

### 13.4.3.8.3 S-i80 interface

Figure 13-37. S-i80 I/F Timing Diagram

- $T1 \geq 1$  clock cycle.
- $T2 \geq 0$  clock cycle.
- $T3 \geq 1$  clock cycle.
- $T4 \geq 0$  clock cycle.
- $T2 + T3 + T4 > 1$  cycle of Byte clock
- $T5 \geq 10$  clock cycles. (every horizontal blank period)

A display controller generates these signals with its internal clock: SYS\_CS0 / CS1, SYS\_WE, and SYS\_VD. MIPI DSI master decodes the SYS\_ADDR. The following table describes the Command mode Interface address map.

**Table 13-13. Command Mode Interface Address Map**

<b>SYS_ADDR[1:0]</b>	<b>Description</b>
2'b00	Image data
2'b01	Reserved
2'b10	Payload data
2'b11	Packet Header

The following figure shows how MIPI DSI Master makes packet from the image data stream via S-i80 INTERFACE in Command mode. MIPI DSI master makes packet from the first line with DCS command “write\_memory\_start” and the other lines with DCS command “write\_memory\_continue”.

S-I80 I/F Input

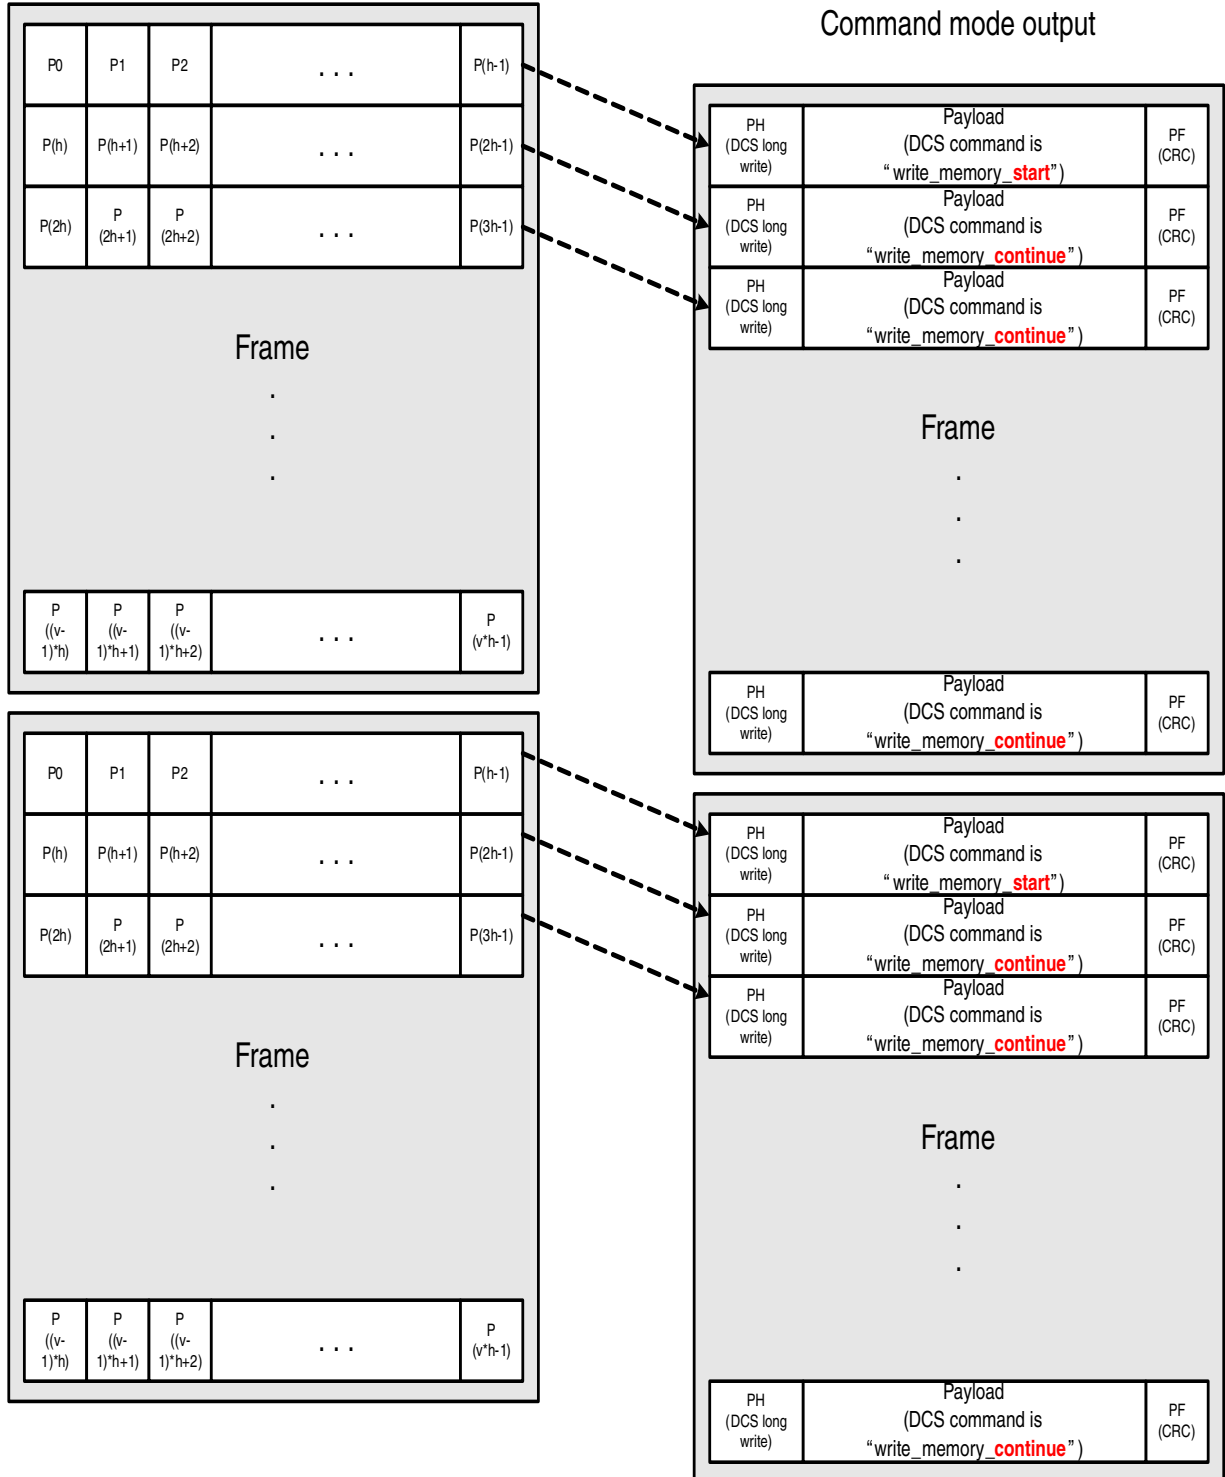

Figure 13-38. Packetizing for MIPI DSI Command Mode from S-i80 I/F

### 13.4.3.8.4 Relation between input transactions and DSI transactions

**Table 13-14. Relation between Input Transactions and DSI Transactions**

Input Interface	Input Transaction	DSI Transaction
RGB	RGB transaction	Specifies the RGB Packet 888, 666, 666 (loosely packed), and 565 should be specified via register configuration.
RGB / S-i80	RGB / S-i80 Image Transaction	Specifies the Data type, that is, "DCS Long Write packet". (DCS command is "memory write start/continue".)
S-i80	S-i80 Command Transaction	Specifies any DSI packet. Bytes in S-i80 transaction should be the same bytes in DSI packets.
SFR	Header and Payload FIFO access	Specifies any DSI Packets. Bytes in APB transaction should be the same bytes in DSI packets.

### 13.4.3.8.5 PPI interface timing and protocol

#### 13.4.3.8.5.1 Initialization after power-on / reset

Figure 13-39. Timing Diagram of Initialization

13.4.3.8.5.2 High speed data transfer

Figure 13-40. Timing Diagram of High Speed Data Transfer

### 13.4.3.8.5.3 Low power data transfer

Figure 13-41. Timing Diagram of Low Power Data Transfer

#### 13.4.3.8.5.4 Ultra-Low power state

Figure 13-42. Timing Diagram of Ultra Low Power State

### 13.4.3.8.5.5 Trigger function

**Figure 13-43. Diagram of Trigger Function “Remote Reset”**

There are four types of trigger commands:

- 01100010 : remote reset – forward direction
- 01011101 : Tearing Effect – reverse direction
- 00100001 : Acknowledge – reverse direction
- 10100000 : Unknown

If DSI D-PHY received these signals, D-PHY indicates trigger function to protocol layer.

#### 13.4.3.8.5.6 Turn-around and low power data receiving

Figure 13-44. Timing Diagram of Bus-Turn-Around

13.4.3.8.5.7 TE signaling

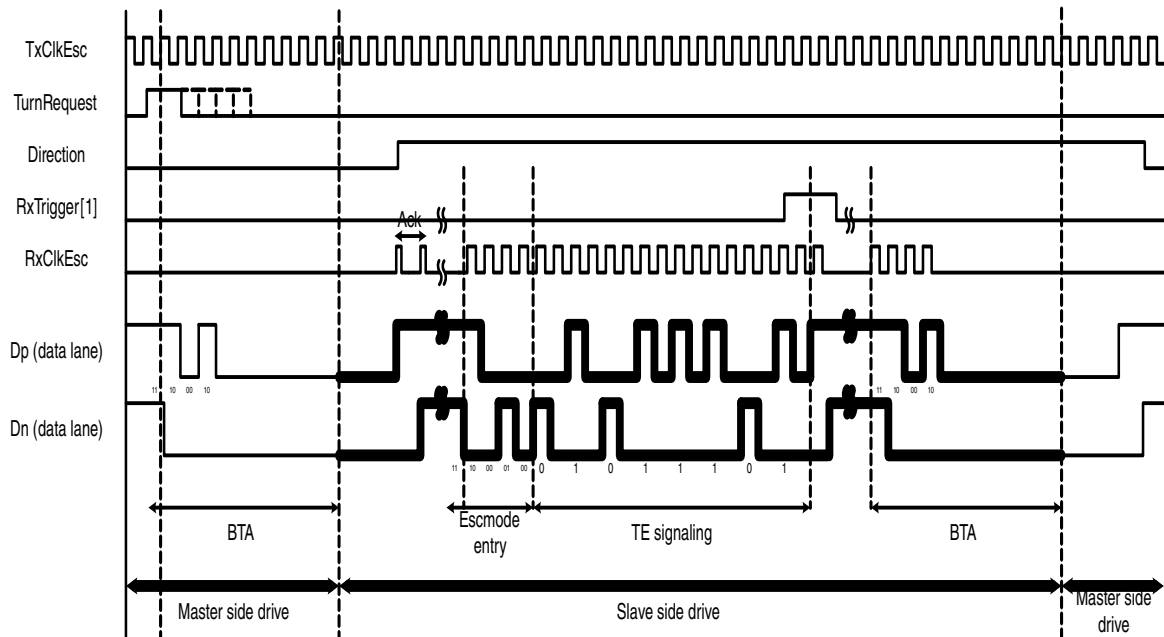

Figure 13-45. TE Signaling

### 13.4.3.9 Configuration

#### 13.4.3.9.1 Video mode VS Command mode

MIPI DSI Master Block supports two modes, namely, Video mode and Command mode. Command mode uses RGB interface and S-i80 interface. Mode can change via SFRs.

#### 13.4.3.9.2 Dual display VS Single display

##### 13.4.3.9.2.1 Dual display

MIPI DSI Master supports dual display configuration in Command mode only, that is, both main and sub display image should be transmitted via S-i80 INTERFACE.

##### 13.4.3.9.2.2 Single display

For single display configuration, use video mode or command mode.

### 13.4.3.9.3 PLL

To transmit Image data, MIPI DSI Master Block needs high frequency clock (80 MHz ~ 1.5 GHz) generated by PLL.

To configure PLL, MIPI DSI Master comprises of SFRs and corresponding interface signals. PLL is embedded in PHY module. You should use other PLL in SoC if it meets the timing specification.

### 13.4.3.9.4 Buffer

In MIPI DSI standard specification, DSI Master sends image stream in burst mode. The image stream transmits in high-speed and bit-clock frequency. This mode allows the device to stay in stop state longer to reduce power consumption. For this mode, MIPI DSI Master has a line buffer to store one complete line and send it faster at the next line time.

## 13.4.3.10 Application Scenario

### 13.4.3.10.1 Display mode

#### 13.4.3.10.1.1 Video mode

Video mode starting sequence:

1. Set RGB I/F in Display Controller (RGB888), also set Video mode at MIPI DSI Master
2. Configure all parameters for displaying image (define resolution, back porch, front porch, data lane number, HS clock frequency (byte clock), etc).
3. Start image transmission.

#### 13.4.3.10.1.2 Command mode

Command mode starting sequence:

1. Set S-i80 I/F in Display Controller (RGB888), also set Command mode at MIPI DSI Master
2. Configure all parameters for displaying image.
3. Set the command at MIPI DSI registers using MIPI DCS.

4. S-i80 I/F is just used to transmit image data. The users have to read display peripheral status and write command through MIPI DSI registers.

### 13.4.3.10.2 Programming model

**Table 13-15. Behavior Programming Each Case**

No.	Mode	Case	Pseudo Code
1	Video	Initialize	<ol style="list-style-type: none"> <li>1. reset or power on</li> <li>2. SFR_Write(Display Controller_registers, RGB I/F_888);</li> <li>3. 13.4.4.1 Version Register (MIPI\_DSI\_VERSION)

Address: 3076\_0000h base + 0h offset = 3076\_0000h

MIPI\_DSI\_VERSION field descriptions

Field	Description
VERSION	Specifies the DSIM version information

### 13.4.4.2 MIPI\_DSI\_STATUS

This register reads and checks internal and interface status. It also checks FSM status, Line buffer status, current image line number, and so on.

Address: 3076\_0000h base + 4h offset = 3076\_0004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	PLLSTABLE	Reserved											SWRSTRLS	Reserved		DIRECTION
W	[Shaded area indicating write protection]															
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

## MIPI DSI Host Controller (MIPI\_DSI)

### MIPI\_DSI\_STATUS field descriptions

Field	Description
31 PLLSTABLE	D-PHY PLL generates stable byteclk.
30–21 Reserved	This field is reserved.
20 SWRSTRLS	Specifies the software reset status 0 Reset state 1 Release state
19–17 Reserved	This field is reserved.
16 DIRECTION	Specifies the data direction indicator 0 Forward direction 1 Backward direction
15–11 Reserved	This field is reserved.
10 TXREADYHCLK	Specifies the HS clock ready at clock lane 0 Not ready for transmitting HS data at clock lane 1 Ready for transmitting HS data at clock lane
9 ULPSCLK	Specifies the ULPS indicator at clock lane 0 No ULPS in clock lane 1 ULPS in clock lane

Table continues on the next page...

## MIPI\_DSI\_STATUS field descriptions (continued)

Field	Description
8 STOPSTATECLK	Specifies the stop state indicator at clock lane  0 No stop state in clock lane 1 Stop state in clock lane
7–4 ULPSDAT[3:0]	Specifies the ULPS indicator at data lanes <ul style="list-style-type: none"> <li>• UlpDat[0]: Data lane 0</li> <li>• UlpDat[1]: Data lane 1</li> <li>• UlpDat[2]: Reserved</li> <li>• UlpDat[3]: Reserved</li> </ul> 0 No ULPS in each data lane 1 ULPS in each data lane
STOPSTATEDAT[3:0]	Specifies the stop state indicator at data lane <ul style="list-style-type: none"> <li>• StopstateDat[0]: Data lane 0</li> <li>• StopstateDat[1]: Data lane 1</li> <li>• StopstateDat[2]: Reserved</li> <li>• StopstateDat[3]: Reserved</li> </ul>

### 13.4.4.3 RGB Status Register (MIPI\_DSI\_RGB\_STATUS)

Address: 3076\_0000h base + 8h offset = 3076\_0008h

**MIPI\_DSI\_RGB\_STATUS field descriptions**

Field	Description
31 CMDMODE_INSEL	Specifies the command mode input selection

Table continues on the next page...

## MIPI\_DSI\_RGB\_STATUS field descriptions (continued)

Field	Description
	0 Using RGB video interface 1 Using S-i80 interface
30–13 Reserved	This field is reserved.
RGBSTATE[12:0]	Specifies the RGB packetize FSM status  0x0001 IDLE 0x0002 STOP 0x0004 VSYS 0x0008 VSE 0x0010 HSS 0x0020 HSA 0x0040 HSE 0x0080 HBP 0x0100 RGB 0x0200 NULL 0x0400 HFP 0x0800 EOT 0x1000 NHOLD

## 13.4.4.4 MIPI\_DSI\_SWRST

Address: 3076\_0000h base + Ch offset = 3076\_000Ch

## MIPI\_DSI\_SWRST field descriptions

Field	Description
31–17 Reserved	This field is reserved.
16 FUNCRST	<p>Specifies the software reset (High active).</p> <p>“Function reset” resets all FF in MIPI DSIM (except SFRs: STATUS, RGB_STATUS, SWRST, CLKCTRL, TIMEOUT, CONFIG, ESCMODE<sup>1</sup>, MDRESOL, MVPORCH, MHPORCH, MSYNC, INTMSK, SDRESOL, S3D_CTL, P3D_CTL, MIC_CTL, P3D_ON_MIC_OFF_HSA, P3D_OFF_MIC_ON_HSA, P3D_ON_MIC_ON_HSA, P3D_ON_MIC_OFF_HFP, P3D_OFF_MIC_ON_HFP, P3D_ON_MIC_ON_HFP, MULTI_PKT, FIFOTHLD, FIFOCTRL<sup>2</sup>, MEMACCHR, PLLCTRL, PLLTMR, PHYACCHR, and VERINFORM).</p> <p>0 Standby 1 Reset</p>
15–1 Reserved	This field is reserved.
0 SWRST	<p>Specifies the software reset (High active).</p> <p>“Software reset” resets all FF in MIPI DSIM (except some SFRs: STATUS, SWRST, CLKCTRL, PLLCTRL, PLLTMR, PHYTUNE, and VERINFORM).</p> <p>0 Standby 1 Reset</p>

1. ForceStopstate, CmdLpdt, TxLpdt

2. nInitRx, nInitSfr, nInitI80, nInitSub, nInitMD

### 13.4.4.5 Clock Control Register (MIPI\_DSI\_CLKCTRL)

Address: 3076\_0000h base + 10h offset = 3076\_0010h

**MIPI\_DSI\_CLKCTRL field descriptions**

Field	Description
31 TXREQUESTHCLK	Specifies the HS clock request for HS transfer at clock lane (Turn on HS clock)
30 Reserved	This field is reserved.
29 DPHY_SEL	D-PHY Select 0 1.5 Gbps D-PHY (default) 1 1 Gbps D-PHY

*Table continues on the next page...*

**MIPI\_DSI\_CLKCTRL field descriptions (continued)**

Field	Description
28 ESCCLKEN	Enables the escape clock generating prescaler  0 Disables 1 Enables
27 PLLBYPASS	Sets the PLLBypass signal connected to D-PHY module input for selecting clock source bit. This bit must be set to 0.  0 PLL output 1 External Serial clock
26–25 BYTECLKSRC	Selects byte clock source. (It must be 2'b00.) 00 = D-PHY PLL (default). PLL_out clock is used to generate ByteClk by dividing 8.
24 ByteClkEn	Enables byte clock  0 Disables 1 Enables
23–19 LANEESCCLKEN	Enables escape clock for D-phy lane <ul style="list-style-type: none"> <li>• LaneEscClkEn[0] = Clock lane</li> <li>• LaneEscClkEn[1] = Data lane 0</li> <li>• LaneEscClkEn[2] = Data lane 1</li> <li>• LaneEscClkEn[3] = Reserved</li> <li>• LaneEscClkEn[4] = Reserved</li> </ul> 0 Disables 1 Enables
18–16 Reserved	This field is reserved.
ESCPRESCALER	Specifies the escape clock prescaler value. The escape clock frequency range varies up to 20 MHz.  <b>NOTE:</b> The requirement for BTA is that the Host Escclk frequency should range between 66.7 ~ 150% of the peripheral escape clock frequency.  EscClk = ByteClk / (EscPrescaler)

**13.4.4.6 MIPI\_DSI\_TIMEOUT**

Address: 3076\_0000h base + 14h offset = 3076\_0014h

### MIPI\_DSI\_TIMEOUT field descriptions

Field	Description
31–24 Reserved	This field is reserved.
23–16 BTAOUT	<p>Specifies the timer for BTA.</p> <p>This register specifies time out from BTA request to change the direction with respect to Tx escape clock.</p>
LPDRTOU	<p>Specifies the timer for LP Rx mode timeout. This register specifies time out on how long RxValid deasserts, after RxLpdt asserts with respect to Tx escape clock.</p> <p>RxValid specifies Rx data valid indicator.</p> <p>RxLpdt specifies an indicator that D-phy is under RxLpdt mode.</p> <p>RxValid and RxLpdt specifies signal from D-phy.</p>

### 13.4.4.7 MIPI\_DSI\_CONFIG

This register configures MIPI DSI master such as data lane number, input interface, porch area, frame rate, BTA, LPDT, ULPS, and so on.

Address: 3076\_0000h base + 18h offset = 3076\_0018h

<p>27 SYNCINFORM</p>	<p>Selects Sync Pulse or Event mode in Video mode In command mode, this bit is ignored.</p> <p>0 Event mode (non burst, burst) 1 Pulse mode (non burst only)</p>
--------------------------	--

<p>26 BURSTMODE</p>	<p>Selects Burst mode in Video mode In Non-burst mode, RGB data area is filled with RGB data and Null packets, according to input bandwidth of RGB interface. In Burst mode, RGB data area is filled with RGB data only.</p>
-------------------------	--

Table continues on the next page...

## MIPI\_DSI\_CONFIG field descriptions (continued)

Field	Description
	In command mode, this bit is ignored.  0 Non-burst mode 1 Burst mode
25 VIDEOMODE	Specifies display configuration
24 AUTOMODE	Specifies auto vertical count mode  In Video mode, the vertical line transition uses line counter configured by VSA, VBP, and Vertical resolution.  If this bit is set to '1', the line counter does not use VSA and VBP registers.  In command mode, this bit is ignored.  0 Configuration mode 1 Auto mode
23 HSEDISABLEMODE	In Vsync pulse and Vporch area, MIPI DSI master transfers only Hsync start packet to MIPI DSI slave at MIPI DSI spec 1.1r02. This bit transfers Hsync end packet in Vsync pulse and Vporch area (optional).  In command mode, this bit is ignored.  0 Disables transfer 1 Enables transfer
22 HFPDISABLEMODE	Specifies HFP disable mode. If this bit set, DSI master ignores HFP area in Video mode.  In command mode, this bit is ignored.  0 Enables 1 Disables
21 HBPDISEMODE	Specifies HBP disable mode. If this bit set, DSI master ignores HBP area in Video mode.  In command mode, this bit is ignored.  0 Enables 1 Disables
20 HSADISEMODE	Specifies HSA disable mode. If this bit set, DSI master ignores HSA area in Video mode.  In command mode, this bit is ignored.  0 Enables 1 Disables
19–18 MAINVC	Specifies virtual channel number for main display
17–16 SUBVC	Specifies virtual channel number for sub display
15 Reserved	This field is reserved.
14–12 MAINPIXFORMAT	Specifies pixel stream format for main display  000 3 bpp (for Command mode only) 001 8 bpp (for Command mode only) 010 12 bpp (for Command mode only)

*Table continues on the next page...*

**MIPI\_DSI\_CONFIG field descriptions (continued)**

Field	Description
	011 16 bpp (for Command mode only) 100 16-bit RGB (565) (for Video mode only) 101 18-bit RGB (666: packed pixel stream) (for Video mode only) 110 18-bit RGB (666: loosely packed pixel stream) for Common 111 24-bit RGB (888) for common
11 Reserved	This field is reserved.
10–8 SUBPIXFORMAT	Specifies pixel stream format for main display  000 3 bpp (for Command mode only) 001 8 bpp (for Command mode only) 010 12 bpp (for Command mode only) 011 16 bpp (for Command mode only) 100 16-bit RGB (565) (for Video mode only) 101 18-bit RGB (666: packed pixel stream) (for Video mode only) 110 18-bit RGB (666: loosely packed pixel stream) for Common 111 24-bit RGB (888) for common
7 Reserved	This field is reserved.
6–5 NUMOFDATLANE	Sets the data lane number  00 Data lane 0 ( 1 data lane) 01 Data lane 0 ~ 1 (2 data lanes) 10 Reserved. 11 Reserved.
LANEEN[4:0]	Enables the lane. If Lane_EN is disabled, the lane ignores input and drives initial value through output port. <ul style="list-style-type: none"> <li>• LaneEn[0] = Clock lane enabler</li> <li>• LaneEn[1] = Data lane 0 enabler</li> <li>• LaneEn[2] = Data lane 1 enabler</li> <li>• LaneEn[3] = Reserved</li> <li>• LaneEn[4] = Reserved</li> </ul>

### 13.4.4.8 Escape Mode Register (MIPI\_DSI\_ESCMODE)

This register configures MIPI DSI master.

Address: 3076\_0000h base + 1Ch offset = 3076\_001Ch

**MIPI\_DSI\_ESCMODE field descriptions**

Field	Description
31–21 STOPSTATE_CNT	After transmitting read packet or write “set_tear_on” command, BTA requests to D-phy automatically. This counter value specifies the interval value between transmitting read packet (or write “set_tear_on” command) and BTA request. 11'h000 = 2 EscClk

*Table continues on the next page...*

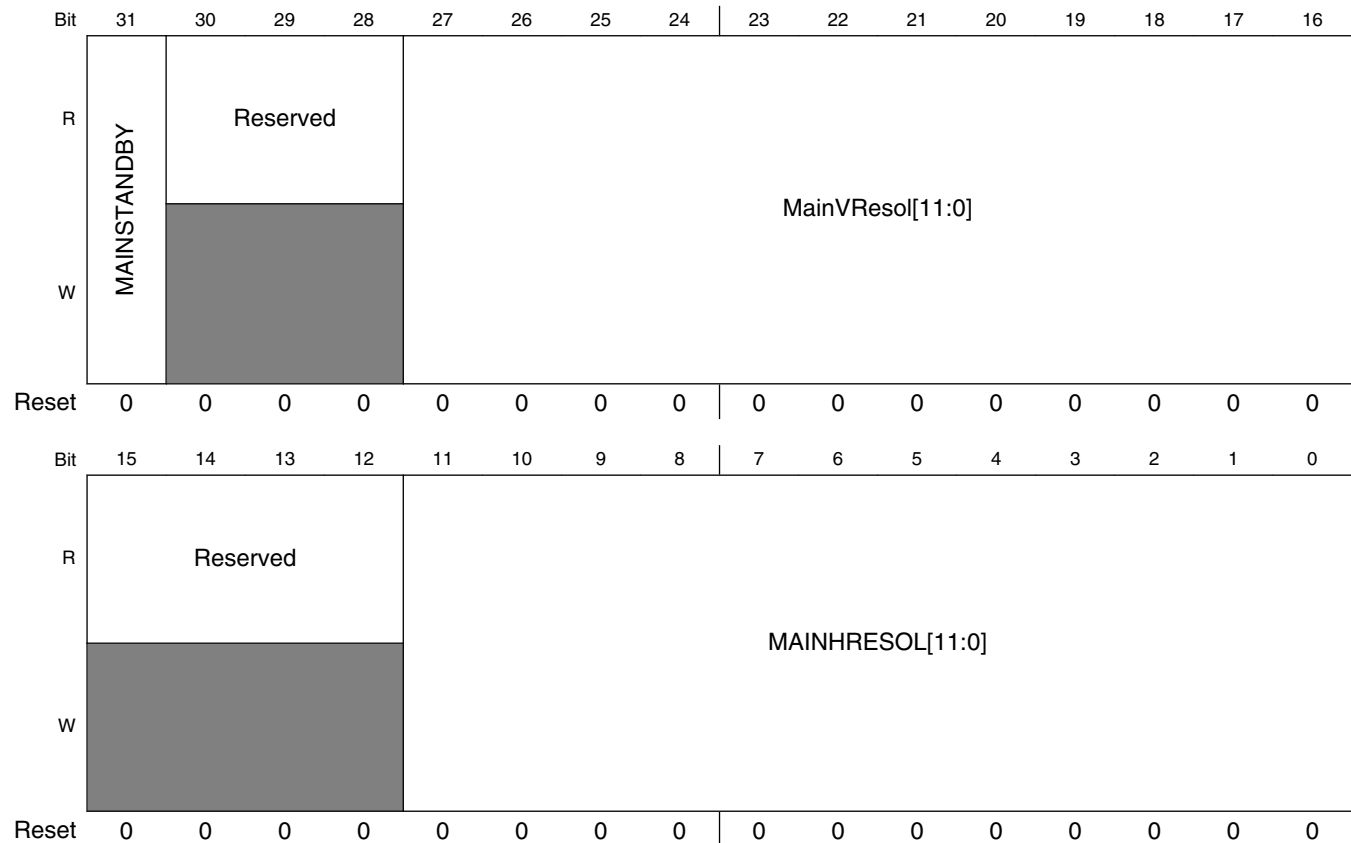

## MIPI\_DSI\_ESCMODE field descriptions (continued)

Field	Description
	11'h001 = 2 EscClk + 1 EscClk ~ 11'h3FF = 2 EscClk + 1023 EscClk
20 FORCESTOPSTATE	Forces Stopstate for D-PHY
19–17 Reserved	This field is reserved.
16 FORCEBTA	Forces Bus Turn Around 1 = Sends the protocol layer request to D-PHY. MIPI DSI peripheral becomes master after BTA sequence. This bit clears automatically after receiving BTA acknowledge from MIPI DSI peripheral.
15–8 Reserved	This field is reserved.
7 CMDLPDT	Specifies LPDT transfers command in SFR FIFO 0 HS Mode 1 LP Mode
6 TXLPDT	Specifies data transmission in LP mode (all data transfer in LPDT) 0 HS Mode 1 LP Mode
5 Reserved	This field is reserved.
4 TXTRIGGERST	Specifies remote reset trigger function. After trigger operation, these bits will be cleared automatically.
3 TXULPSDAT	Specifies ULPS request for data lane. Manually clears after ULPS exit.
2 TXULPSEXIT	Specifies ULPS exit request for data lane. Manually clears after ULPS exit.
1 TXULPSCLK	Specifies ULPS request for clock lane. Manually clears after ULPS exit.
0 TXULPSCLKEXIT	Specifies ULPS exit request for clock lane. Manually clears after ULPS exit.

### 13.4.4.9 Main Display Image Resolution Register (MIPI\_DSI\_MDRESOL)

Address: 3076\_0000h base + 20h offset = 3076\_0020h

#### MIPI\_DSI\_MDRESOL field descriptions

Field	Description
31 MAINSTANDBY	Specifies standby for receiving DISPCON output in Command mode after setting all configuration. Standby should be set after configuration (resolution, reqtype, pixelform, and so on) is set for command mode. In Video mode, if this bit value is 0, data is not transferred.  0 Not ready 1 Standby
30–28 Reserved	This field is reserved.
27–16 MainVResol[11:0]	Specifies Vertical resolution (1 ~ 2047)
15–12 Reserved	This field is reserved.
MAINHRESOL[11:0]	Specifies Horizontal resolution (1 ~ 2047)

### 13.4.4.10 Main Display VPORCH Register (MIPI\_DSI\_MVPORCH)

**NOTE**

Transfers command packets after Stable VFP area. Display controller VFP lines should be set based on sum of these values: Stable VFP, command allowing area and command masked area. See the section for transferring general data in Video mode.

Address: 3076\_0000h base + 24h offset = 3076\_0024h

**MIPI\_DSI\_MVPORCH field descriptions**

Field	Description
31–28 CMDALLOW	Specifies the number of horizontal lines, where command packet transmission is allowed after Stable VFP period. For more information, see <a href="#">Figure 13-36</a> .
27 Reserved	This field is reserved.

Table continues on the next page...

### MIPI\_DSI\_MVPORCH field descriptions (continued)

Field	Description
26–16 STABLEVFP[10:0]	Specifies the number of horizontal lines, where command packet transmission is not allowed after end of active region. For more information, see <a href="#">Figure 13-36</a> .  <b>NOTE:</b> In Command mode, these bits are ignored.
15–11 Reserved	This field is reserved.
MAINVBP[10:0]	Specifies vertical back porch width for Video mode (line count). In Command mode, these bits are ignored.

### 13.4.4.11 MIPI\_DSI\_MHPORCH

Address: 3076\_0000h base + 28h offset = 3076\_0028h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### MIPI\_DSI\_MHPORCH field descriptions

Field	Description
31–16 MAINHFP[15:0]	Specifies the horizontal front porch width for Video mode. HFP is specified using blank packet. These bits specify the word counts for blank packet in HFP. In Command mode, these bits are ignored.
MAINHBP[15:0]	Specifies the horizontal back porch width for Video mode. HBP is specified using blank packet. These bits specify the word counts for blank packet in HBP. In Command mode, these bits are ignored.

### 13.4.4.12 MIPI\_DSI\_MS SYNC

Address: 3076\_0000h base + 2Ch offset = 3076\_002Ch

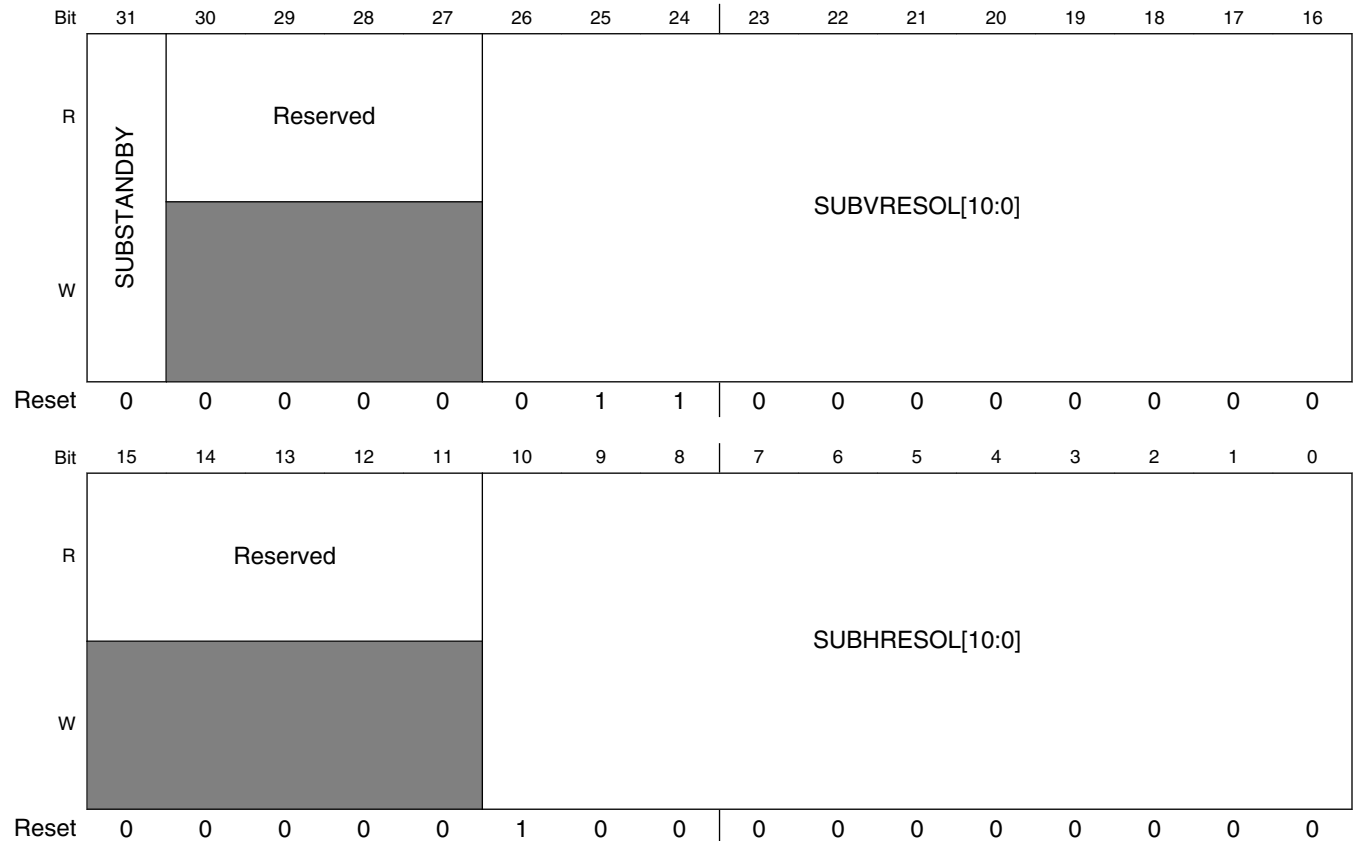

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### MIPI\_DSI\_MS SYNC field descriptions

Field	Description
31–22 MAINVSA[9:0]	Specifies the vertical sync pulse width for Video mode (Line count). In command mode, these bits are ignored.
21–16 Reserved	This field is reserved.
MAINHSA[15:0]	Specifies the horizontal sync pulse width for Video mode. HSA is specified using blank packet. These bits specify word counts for blank packet in HSA. In command mode, these bits are ignored.

### 13.4.4.13 Sub Display Image Resolution Register (MIPI\_DSI\_SDRESOL)

Address: 3076\_0000h base + 30h offset = 3076\_0030h

**MIPI\_DSI\_SDRESOL field descriptions**

Field	Description
31 SUBSTANDBY	Specifies standby for receiving DISPCON output in Command mode after setting all configuration. Standby should be set after configuration (resolution, reftype, pixelform, and so on) is set for command mode. In Video mode, this bit is ignored. 0 Not ready 1 Standby
30-27 Reserved	This field is reserved.
26-16 SUBVRESOL[10:0]	Specifies the Vertical resolution (1 ~ 1024)
15-11 Reserved	This field is reserved.
SUBHRESOL[10:0]	Specifies the Horizontal resolution (1 ~ 1024)

### 13.4.4.14 Interrupt Source Register (MIPI\_DSI\_INTSRC)

This register identifies interrupt sources.

Internal block error, data transmit interrupt, inter-layer (D\_PHY) error, etc.

The bits are set even if they are masked off by DSIM\_INTMSK\_REG.

Write '1' to clear the Interrupt.

Address: 3076\_0000h base + 34h offset = 3076\_0034h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R						Reserved			Reserved				Reserved			
	PLLSTABLE	SWRSTRELEASE	SFRPLFIFOEMPTY	SFRPHFIFOEMPTY	SYNCOVERRIDE		BUSTURNOVER	FRAMEDONE			LPDRTOU	TATOUT		RXDATDONE	RXTE	RXACK
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

## MIPI DSI Host Controller (MIPI\_DSI)

### MIPI\_DSI\_INTSRC field descriptions

Field	Description
31 PLLSTABLE	Indicates that D-phy PLL is stable.
30 SWRSTRELEASE	Releases the software reset.
29 SFRPLFIFOEMPTY	Specifies the SFR payload FIFO empty.
28 SFRPHFIFOEMPTY	Specifies the SFR Packet Header FIFO empty
27 SYNCOVERRIDE	Indicates that other DSI command transfer have overridden sync timing.
26 Reserved	This field is reserved.
25 BUSTURNOVER	Indicates when bus grant turns over from DSI slave to DSI master.
24 FRAMEDONE	Indicates when MIPI DSIM transfers the whole image frame. <b>NOTE:</b> If Hsync is not received during two line times, internal timer is timed out and this bit is flagged.
23–22 Reserved	This field is reserved.
21 LPDRTOU	Specifies the LP Rx timeout. See time out register (0x10).
20 TATOU	Turns around Acknowledge Timeout. See time out register (0x10).
19 Reserved	This field is reserved.

Table continues on the next page...

## MIPI\_DSI\_INTSRC field descriptions (continued)

Field	Description
18 RXDATDONE	Completes receiving data
17 RXTE	Receives TE Rx trigger
16 RXACK	Receives ACK Rx trigger
15 ERRRXECC	Specifies the ECC multi bit error in LPDR
14 ERRRXCRC	Specifies the CRC error in LPDR
13 Reserved	This field is reserved.
12 Reserved	This field is reserved.
11 ERRESC1	Specifies the escape mode entry error lane 1. For more information, refer to standard D-PHY specification.
10 ERRESC0	Specifies the escape mode entry error lane 0. For more information, refer to standard D-PHY specification.
9 Reserved	This field is reserved.
8 Reserved	This field is reserved.
7 ERRSYNC1	Specifies the LPDT Sync Error lane1. For more information, refer to standard D-PHY specification.
6 ERRSYNC0	Specifies the LPDT Sync Error lane0. For more information, refer to standard D-PHY specification.
5 Reserved	This field is reserved.
4 Reserved	This field is reserved.
3 ERRCONTROL1	Controls Error lane1. For more information, refer to standard D-PHY specification.
2 ERRCONTROL0	Controls Error lane0. For more information, refer to standard D-PHY specification.
1 ERRCONTENTLP0	Specifies the LP0 Contention Error (only lane0, because BTA occurs at lane0 only). For more information, refer to standard D-PHY specification.
0 ERRCONTENTLP1	Specifies the LP1 Contention Error (only lane0, because BTA occurs at lane0 only). For more information, refer to standard D-PHY specification.

### 13.4.4.15 Interrupt Mask Register (MIPI\_DSI\_INTMSK)

This register masks interrupt sources.

Address: 3076\_0000h base + 38h offset = 3076\_0038h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R						Reserved			Reserved				Reserved			
W																
Reset	1	0	1	1	1	0	1	1	0	0	1	1	1	1	1	1

### MIPI\_DSI\_INTMSK field descriptions

Field	Description
31 MSKPLLSTABLE	Indicates that D-PHY PLL is stable.
30 MSKSWRSTRELEASE	Releases software reset.
29 MSKSFRPLFIFOEMPTY	Empties SFR payload FIFO.
28 MSKSFRPHFIFOEMPTY	Interrupt Mask for SFR packet header FIFO empty
27 MSKSYNCOVERRIDE	Indicates that other DSI command transfer have overridden sync timing.
26 Reserved	This field is reserved.
25 MSKBUSTURNOVER	Indicates when bus grant turns over from DSI slave to DSI master.
24 MSKFRAMEDONE	Indicates when MIPI DSIM transfers whole image frame.
23–22 Reserved	This field is reserved.
21 MSKLPDRTOU	Specifies LP Rx timeout. See time out register (0x10).
20 MSKTATOUT	Specifies turnaround acknowledge timeout. See time out register (0x10)
19 Reserved	This field is reserved.

Table continues on the next page...

**MIPI\_DSI\_INTMSK field descriptions (continued)**

Field	Description
18 MSKRXDATDONE	Specifies completion of data receiving
17 MSKRXTE	Specifies receipt of TE Rx trigger
16 MSKRXACK	Specifies receipt of ACK Rx trigger
15 MSKRXECC	Specifies ECC multibit error in LPDR
14 MSKRXCRC	Specifies CRC error in LPDR
13 Reserved	This field is reserved.
12 Reserved	This field is reserved.
11 MSKESC1	Specifies escape mode entry error in lane1. For more information, refer to standard D-PHY specification.
10 MSKESC0	Specifies escape mode entry error in lane0. For more information, refer to standard D-PHY specification.
9 Reserved	This field is reserved.
8 Reserved	This field is reserved.
7 MSKSYNC1	Specifies LPDT sync error in lane1. For more information, refer to standard D-PHY specification.
6 MSKSYNC0	Specifies LPDT sync error in lane0. For more information, refer to standard D-PHY specification.
5 Reserved	This field is reserved.
4 Reserved	This field is reserved.
3 MSKCONTROL1	Controls error in lane1. For more information, refer to standard D-PHY specification.
2 MSKCONTROL0	Controls error in lane0. For more information, refer to standard D-PHY specification.
1 MSKCONTENTLP0	Specifies LP0 contention error. For more information, refer to standard D-PHY specification.
0 MSKCONTENTLP1	Specifies LP1 contention error. For more information, refer to standard D-PHY specification.

### 13.4.4.16 Packet Header FIFO Register (MIPI\_DSI\_PKTHDR)

This register is the FIFO for packet header to send DSI packets.

Address: 3076\_0000h base + 3Ch offset = 3076\_003Ch

#### MIPI\_DSI\_PKTHDR field descriptions

Field	Description
31–24 Reserved	This field is reserved.
PACKETHEADER	Writes the packet header of Tx packet. <ul style="list-style-type: none"> <li>• [7:0] = DI</li> <li>• [15:8] = Dat0 (Word Count lower byte for long packet)</li> <li>• [23:16] = Dat1 (Word Count upper byte for long packet)</li> </ul>

### 13.4.4.17 Payload FIFO Register (MIPI\_DSI\_PAYLOAD)

This register is the FIFO for packet header to send DSI packets.

Address: 3076\_0000h base + 40h offset = 3076\_0040h

#### MIPI\_DSI\_PAYLOAD field descriptions

Field	Description
PAYLOAD	Writes the Payload of Tx packet

### 13.4.4.18 Payload FIFO Register (MIPI\_DSI\_RXFIFO)

This register is the gate of FIFO read.

Address: 3076\_0000h base + 44h offset = 3076\_0044h

#### MIPI\_DSI\_RXFIFO field descriptions

Field	Description
RXFIFO	In the Rx mode, you can read Rx data through this register. <b>NOTE:</b> The CRC in packet is not stored in RxFIFO.

### 13.4.4.19 FIFO Threshold Level Register (MIPI\_DSI\_FIFOTHLD)

Address: 3076\_0000h base + 48h offset = 3076\_0048h

#### MIPI\_DSI\_FIFOTHLD field descriptions

Field	Description
31–9 Reserved	This field is reserved.
WFULLLEVELSFR	Almost full level of SFR payload FIFO

### 13.4.4.20 FIFO Status and Control Register (MIPI\_DSI\_FIFOCTRL)

Address: 3076\_0000h base + 4Ch offset = 3076\_004Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

**MIPI\_DSI\_MEMACCHR field descriptions (continued)**

<b>Field</b>	<b>Description</b>
15 PGEN_SD	Sub display FIFO memory power gating
14 RETN_SD	Sub display FIFO memory Retention
13–11 EMAB_SD	Sub display FIFO memory B port margin adjustment
10–8 EMAA_SD	Sub display FIFO memory A port margin adjustment
7 PGEN_MD	Main display FIFO memory power gating
6 RETN_MD	Main display FIFO memory Retention
5–3 EMAB_MD	Main display FIFO memory B port margin adjustment
EMAA_MD	Main display FIFO memory A port margin adjustment

### 13.4.4.22 MIPI\_DSI\_MULTI\_PKT

Address: 3076\_0000h base + 78h offset = 3076\_0078h

#### MIPI\_DSI\_MULTI\_PKT field descriptions

Field	Description
31 Reserved	This field is reserved.
30 MULTI_PKT_EN	Specifies the send multi command packets on single transmission. Multi command packet can transfer by only HS mode. 0 Send single command packet 1 Send multi command packets
29 PKT_GO_EN	Specifies the send command packet(s) per frame enable . Packet go can transfer by only HS mode.

*Table continues on the next page...*

## MIPI\_DSI\_MULTI\_PKT field descriptions (continued)

Field	Description
	0 Send command packet(s) during every VFP 1 Send command packet(s) during 1frame VFP
28 PKT_GO_RDY	Specifies the send command packet(s) on this frame VFP. If packet transferred or PKT_Go_EN is disabled, this bit goes to 1'b0.
27-16 PKT_SEND_ CNT_REF	Specifies the command packet(s) send point indicator. That value is 1H time + D-PHY LP-HS-LP latency by ByteCLK. Do not use '0'.
MULTI_PKT_ CNT_REF	Specifies the number of packets on single transmission. Do not use '0' and '1'. 0 and 1 are same as '2'

### 13.4.4.23 1 Gbps D-PHY PLL Control Register (MIPI\_DSI\_PLLCTRL\_1G)

This register configures 1Gbps D-PHY PLL control, D-PHY, clock range indication, and so on.

Address: 3076\_0000h base + 90h offset = 3076\_0090h

**MIPI\_DSI\_PLLCTRL\_1G field descriptions**

Field	Description
31–16 Reserved	This field is reserved.
15–12 HSZEROCTL[3:0]	1 Gbps D-PHY HS-Zero driving timing control.
11–8 FREQ_BAND	1 Gbps D-PHY Timing control for D-PHY global operation timing.
7 Reserved	This field is reserved.

*Table continues on the next page...*

**MIPI\_DSI\_PLLCTRL\_1G field descriptions (continued)**

<b>Field</b>	<b>Description</b>
6-4 PREPRCTL[2:0]	1 Gbps D-PHY PLL Tclk-prepare and Ths-prepare driving control.
3 Reserved	This field is reserved.
PRPRCTLCLK[2:0]	1 Gbps D-PHY PLL Ths-prepare driving time control

### 13.4.4.24 PLL Control register (MIPI\_DSI\_PLLCTRL)

This register configures PLL control, D-PHY, clock range indication, and so on.

Address: 3076\_0000h base + 94h offset = 3076\_0094h

**MIPI\_DSI\_PLLCTRL field descriptions**

Field	Description
31–26 Reserved	This field is reserved.

*Table continues on the next page...*

**MIPI\_DSI\_PLLCTRL field descriptions (continued)**

Field	Description
25 DPDNSWAP_CLK	Swaps Dp / Dn channel of clock lane. If this bit is set, Dp and Dn channel swap each other.
24 DPDNSWAP_DAT	Swaps Dp / Dn channel of Data lanes. If this bit is set, Dp and Dn channel swap each other.
23 PLLEN	Enables PLL
22-20 Reserved	This field is reserved.
19-1 PMS[19:1]	Specifies the PLL PMS value
0 Reserved	This field is reserved.

**13.4.4.25 PLL Control Register 1 (MIPI\_DSI\_PLLCTRL1)**

This register configures D-PHY PLL control (M\_PLLCTL[31:0]).

Address: 3076\_0000h base + 98h offset = 3076\_0098h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### MIPI\_DSI\_PHYCTRL\_B1 field descriptions

Field	Description
B_DPHYCTL0	B_DPHYCTL[31:0] to D-PHY

### 13.4.4.29 D-PHY Master and Slave Analog Block Control Register 2 (MIPI\_DSI\_PHYCTRL\_B2)

D-PHY Master and Slave Analog block characteristics control registers (B\_DPHYCTL).

Address: 3076\_0000h base + A8h offset = 3076\_00A8h

#### MIPI\_DSI\_PHYCTRL\_B2 field descriptions

Field	Description
B_DPHYCTL1	B_DPHYCTL[63:32] to D-PHY

### 13.4.4.30 D-PHY Master Analog Block Control Register 1 (MIPI\_DSI\_PHYCTRL\_M1)

D-PHY Master Analog block characteristics control registers (M\_DPHYCTL).

Address: 3076\_0000h base + ACh offset = 3076\_00ACh

#### MIPI\_DSI\_PHYCTRL\_M1 field descriptions

Field	Description
M_DPHYCTL0	M_DPHYCTL[31:0] to D-PHY

### 13.4.4.31 D-PHY Master Analog Block Control Register 1 (MIPI\_DSI\_PHYCTRL\_M2)

D-PHY Master Analog block characteristics control registers (M\_DPHYCTL).

Address: 3076\_0000h base + B0h offset = 3076\_00B0h

#### MIPI\_DSI\_PHYCTRL\_M2 field descriptions

Field	Description
M_DPHYCTL1	M_DPHYCTL[63:32] to D-PHY

### 13.4.4.32 D-PHY Timing register (MIPI\_DSI\_PHYTIMING)

D-PHY Master global operating timing registers

Address: 3076\_0000h base + B4h offset = 3076\_00B4h

#### MIPI\_DSI\_PHYTIMING field descriptions

Field	Description
31–16 Reserved	This field is reserved.
15–8 M_TLPXCTL	M_TLPXCTL[7:0] to D-PHY
M_THSEXITCTL	M_THSEXITCTL[7:0] to D-PHY

### 13.4.4.33 MIPI\_DSI\_PHYTIMING1

D-PHY Master global operating timing registers.

Address: 3076\_0000h base + B8h offset = 3076\_00B8h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

M_ THSTRAILCTL	M_THSTRAILCTL[7:0] to D-PHY

## 13.5 MIPI CSI2 Host Controller (MIPI\_CSI2)

### 13.5.1 Overview

The CSI-2 Host Controller is a digital core that implements all protocol functions defined in the MIPI CSI-2 Specification, providing an interface between the System and the MIPI D-PHY, allowing the communication with a MIPI CSI-2 compliant Camera Sensor.

#### 13.5.1.1 Features

The following list summarizes the key features of the MIPI CSI2:

- Compliant to MIPI D-phy standard specification V1.1
  - Compliant to previous version of Samsung D-phy
- Compliant to MIPI CSI2 Standard Specification V1.01r06
- Support primary and secondary Image format
  - YUV420, YUV420 (Legacy), YUV420 (CSPS), YUV422 of 8-bits and 10-bits
  - RGB565, RGB666, RGB888
  - RAW6, RAW7, RAW8, RAW10, RAW12, RAW14
  - Compressed format: 10-6-10, 10-7-10, 10-8-10, 14-10-14
  - All of user defined byte-based Data packet
- Support embedded byte-based non-Image data packet and generic short packets
- Support interleave mode using Virtual channel
- Support up to two D-PHY Rx Data Lanes
- Interfaces
  - Compatible to PPI (Protocol-to-PHY Interface) in MIPI D-PHY Specification
  - Image output data bus width: 32 bit
  - Support four channel virtual channels or data interleave
- Memory

Non-image memory

- 8 KB SRAM for asynchronous clock domain
- This memory can store maximum 4 KB of non-image data per frame.

Image Memory

- 1KB SRAM for image memory
- This memory works as buffering for the difference of input / output bandwidth
- Pixel clock can be gated when no ppi data is coming.

### 13.5.1.2 Block diagram

#### 13.5.1.2.1 Block diagram of camera system with CSIS V3.3

Figure 13-47. Block Diagram of Camera System with CSIS V3.3

## 13.5.1.2.2 MIPI CSI Slave and D-PHY I/F block diagram

Figure 13-48. PPI I/F Block Diagram

### 13.5.1.2.3 MIPI CSI Slave block diagram

Figure 13-49. Block Diagram of CSIS V3.3 Slave Module

### 13.5.1.3 Internal memories

There are some configurable-sized Memories. The following table describes these Memories.

Table 13-16. Internal Memory List

Usage	Memory Type	Size	Description
Generic data	2 port SRAM	8 KB (2048 X 32 bits)	Store the Embedded data or Generic data (This memory can be split several memories and then need mux for those memories)
Image data	2 port SRAM	1 KB (256 x 32 bits)	Store the Image data of Virtual Channel

There is the timing diagram for read memory in the following figure. If the mux for the split memories is needed, register for storing the address is necessary, because the RDATA of memory is prepared at one clock later when the REN and RADDR are accepted.

Figure 13-50. Timing Diagram of Read Memory

## 13.5.2 External Signals

The following table describes the external signals of MIPI CSI:

Table 13-17. MIPI CSI External Signals

Signal	Description	Pad	Mode	Direction
MIPI_CSI_CLK_N	D-PHY Negative D-Phy differential clock line Receiver input	MIPI_CSI_CLK_N	No muxing	I
MIPI_CSI_CLK_P	D-PHY Positive D-Phy differential clock line Receiver input	MIPI_CSI_CLK_P	No muxing	I
MIPI_CSI_D0_N	D-PHY Negative D-Phy differential data line Receiver input	MIPI_CSI_D0_N	No muxing	I
MIPI_CSI_D0_P	D-PHY Positive D-Phy differential data line Receiver input	MIPI_CSI_D0_P	No muxing	I
MIPI_CSI_D1_N	D-PHY Negative D-Phy differential data line Receiver input	MIPI_CSI_D1_N	No muxing	I
MIPI_CSI_D1_P	D-PHY Positive D-Phy differential data line Receiver input	MIPI_CSI_D1_P	No muxing	I

## 13.5.3 Functional Description

### 13.5.3.1 Interface and protocol

### 13.5.3.1.1 D-PHY layer FSM

**Figure 13-51. D-PHY Finite State Machine**

CSIS V3.3 system supports HSDT (High Speed Data Transfer) and ULPS (ULPM–Ultra-Low Power State or Mode) only. There is no trigger function, LPDT, and BTA.

### 13.5.3.1.2 Interface timing and protocol

#### 13.5.3.1.2.1 PPI interface timing and protocol

CSIS V3.3 supports HSDT and ULPM.

##### 13.5.3.1.2.1.1 High speed data transfer

In the following figure, the upper five signals are related with clock lane and the lower six signals are related with data lane. Dp and Dn of upper signals are D-phy channel of clock lane. BYTE\_CLK is generated clock in the D-PHY. Dp and Dn of lower signals are

Data lane. Another signals of lower are Phy Status signals. STOPstate (and STOPstateClk) indicates that differential channel state of D-phy is LP11 (the voltage level of Dp and Dn is 1.2 V)

**Figure 13-52. Timing Diagram of High Speed Data Transfer**

#### 13.5.3.1.2.1.2 Ultra-low power mode

In the following figure, UlpsActiveNot\* and STOPstate\* is in PPI. ULPS command generated by D-PHY Tx is only for D-PHY Rx, it is decoded by D-PHY Rx and transferred to Link with Ulps data.

Figure 13-53. Timing Diagram of Ultra Low Power Mode

### 13.5.3.1.2.2 ISP (CAM I/F) interface

CSIS V3.3 has output signals, which are PIX\_CLK, VVALID, HVALID, BVALID, DATA, StopReqEn, and input signal which is StopReq. PIX\_CLK is output pixel clock what is generated from PCLK or EXTCLK (WRAP\_CLK). VVALID is vertical sync signal. HVALID is horizontal sync signal. BVALID indicates the valid number of bytes, which is only used in User Defined type. DATA is image data bus. DATA bus width is dependent on Image format. Maximum bus width is 24 bits, which is RGB888. The following figure describes the output protocol of MIPI CSIS. All signals are synchronized with the rising edge of PIX\_CLK.

**Figure 13-54. Output Protocol of ISP Wrapper of CSIS V3.3**

The following figure describes timing diagram of ISP wrapper output protocol.

**Figure 13-55. Timing Diagram of ISP Wrapper Output Protocol**

The following table is a timing table of output protocol.

**Table 13-18. Description of Output Protocol**

	Description	Minimum Cycle of Pixel Clock	Maximum Cycle of Pixel clock
t1	Interval between rising of VVALID and first rising of HVALID	Vsync_SIntv + 1 (1 ~ 64)	—
t2	Interval between last falling of DVALID and falling of HVALID	Hsync_LIntv + 1 ( 1 ~ 6 4 )	—
t3	Interval between falling of HVALID and rising of next HVALID	1	—
t4	Interval between rising of HVALID and first rising of DVALID	0	—
t5	Interval between last falling of HVALID and falling of VVALID	Vsync_EIntv (0 ~ 4095)	—
t6	Interval between falling of VVALID and rising of next VVALID	1	—

*13.5.3.1.2.2.1 Handshaking with back pressure*

In the following figure, there are handshaking signals which are StopReqEn and StopReq to stall data flow when the Post-IP needs more clock cycles to process its computation. The handshaking is called as back pressure interface.

**Figure 13-56. Interface between Two IPs**

Under the stoppable condition ( $\text{StopReqEn}$  and  $\text{StopReq} = 1$ ), sync signals ( $\text{VVALID}$ ,  $\text{HVALID}$ ,  $\text{DVALID}$ , and  $\text{BVALID}$ ) are not changed. Only after releasing of the stoppable condition, sync signals can be changed. In the following figure, (b) shows that  $\text{StopReq}$  is ignored when  $\text{StopReqEn}$  is not active.  $\text{StopReqEn}$  is high when the room of memory is greater than  $\text{IMG\_MEM\_FULL\_GAP}$ , because of the delay of full signal propagation,  $\text{IMG\_MEM\_FULL\_GAP}$  must not be set under 4 to avoid memory overflow.

Figure 13-57. Timing Diagram According to StopReqEn and StopReq

13.5.3.1.2.2.2 Normal Data alignment in output Data bus

The following figure describes data alignment of RGB formats.

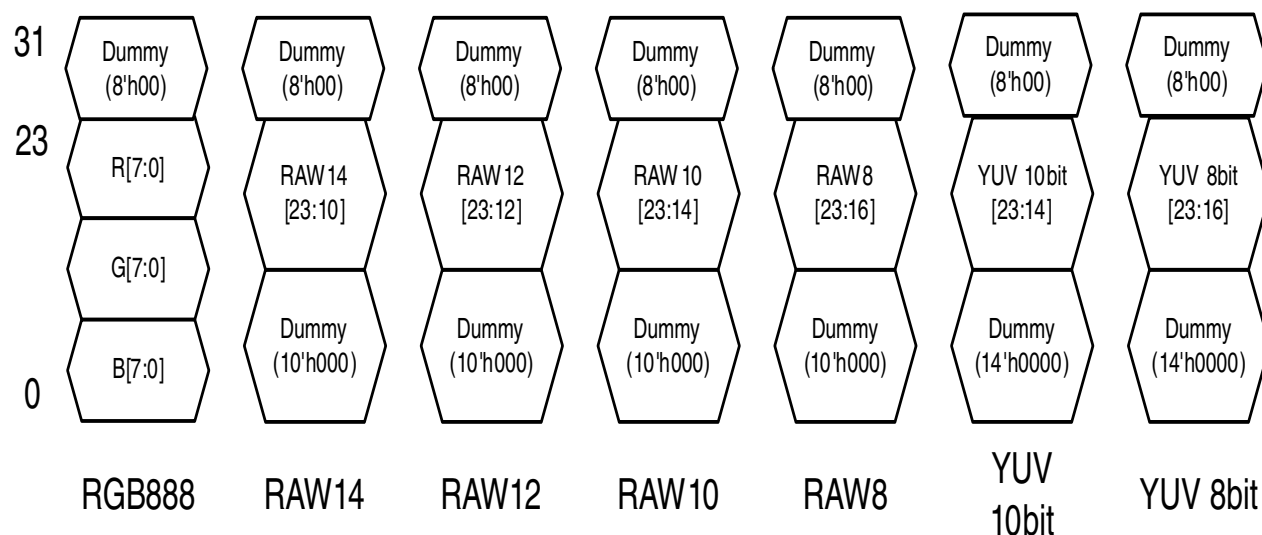

Figure 13-58. RGB Data Alignment

The following figure describes data alignment of RAW and YUV formats.

**Figure 13-59. RAW and YUV Data Alignment**

The following table describes present of each bit in image data bus.

**Table 13-19. MIPI CSIS Output Format in Bus**

Bit #	RGB Format			RAW Format				YUV Format		User Defined Packet
	666	565	14	12	10	8	10	8

The following figure describes the waveform of double component mode.

(a) Double Component Mode of YUV422 8-bit

(b) Double Component Mode of YUV422 10-bit

**Figure 13-60. Waveform of Double Component Mode**

### 13.5.3.2 Configuration

#### 13.5.3.2.1 Image resolution

MIPI CSI Slave block needs the configuration of Image resolution to measure Hsync pulse length exactly and detect frame end.

Vertical resolution register has 16 bits (16'h0001 ~ 16'hFFFF).

Horizontal resolution register has 16 bits (16'h0001 ~ 16'hFFFF).

### 13.5.3.2.2 Image data format

In CSIS V3.3, Image data format can be configured for transferring image data to ISP or CAM I/F.

#### 13.5.3.2.2.1 YUV format

MIPI CSI2 supports YUV formats: YUV420 8-bit, YUV420 10-bit, YUV420 Legacy, YUV420 8-bit Chroma Shifted Pixel Sampling, YUV420 10-bit Chroma Shifted Pixel Sampling, YUV422 8-bit, and YUV422 10-bit.

The following table describes Data type of YUV packets.

**Table 13-22. Data Type of YUV Packets**

Data Type	Description
0x18	YUV420 8-bit
0x19	YUV420 10-bit
0x1A	Legacy YUV420 8-bit
0x1B	Reserved
0x1C	YUV420 8-bit CSPS (Chroma Shifted Pixel Sampling)
0x1D	YUV420 10-bit CSPS (Chroma Shifted Pixel Sampling)
0x1E	YUV422 8-bit
0x1F	YUV422 10-bit

#### 13.5.3.2.2.2 RGB format

MIPI CSI2 supports RGB formats: RGB444, RGB555, RGB565, RGB666, and RGB888.

The following table describes data type of RGB packets.

**Table 13-23. Data Type of RGB Packets**

Data Type	Description
0x20	RGB444 (not support)
0x21	RGB555 (not support)
0x22	RGB565
0x23	RGB666
0x24	RGB888
0x25	Reserved
0x26	
0x27	

### 13.5.3.2.2.3 RAW format (Bayer RGB)

MIPI CSI2 supports RAW formats: RAW6, RAW7, RAW8, RAW10, RAW12, and RAW14.

The following table describes data type of RAW packets.

**Table 13-24. Data Type of RAW Packets**

Data Type	Description
0x28	RAW6
0x29	RAW7
0x2A	RAW8
0x2B	RAW10
0x2C	RAW12
0x2D	RAW14
0x2E	Reserved
0x2F	

### 13.5.3.2.2.4 User defined Byte-based format

CSIS V3.3 supports eight formats of user defined Byte-based data packet.

The following table describes data type of user defined packets.

**Table 13-25. Data Type of RAW Packets**

Data Type	Description
0x30	User defined Byte-based packet 1
0x31	User defined Byte-based packet 2
0x32	User defined Byte-based packet 3
0x33	User defined Byte-based packet 4
0x34	User defined Byte-based packet 5
0x35	User defined Byte-based packet 6
0x36	User defined Byte-based packet 7
0x37	User defined Byte-based packet 8

### 13.5.3.2.2.5 Generic format

CSIS V3.3 supports Generic Short and Long data type packet through only Virtual Channel 0. For the lower size and the Generic type data is not used frequently, it is limited that only the VC 0 supports the Generic format packet.

The intention of the Generic Short Packet data is to provide timing information for the opening / closing of shutters, triggering of flashes, etc. And the Embedded 8-bit contains the additional information of the picture frame.

All the Generic type data in a frame is stored at the SRAM and system is required to pop the data. For the double buffering, the embedded data can be used up to the half of SRAM size (EX: If SRAM is 8 KB allocated for the generic data type then each frame can use up to 4 KB generic data).

**Table 13-26. Generic Short / Long Data Type**

Data Type	Description
0x08	Generic Short Packet Code 1
0x09	Generic Short Packet Code 2
0x0A	Generic Short Packet Code 3
0x0B	Generic Short Packet Code 4
0x0C	Generic Short Packet Code 5
0x0D	Generic Short Packet Code 6
0x0E	Generic Short Packet Code 7
0x0F	Generic Short Packet Code 8
0x12	Embedded 8-bit non Image data (Generic long type)

### 13.5.3.2.2.6 Null and blanking data

For both the null and blanking data types CSIS V3.3 ignore the content of the packet payload data.

**Table 13-27. Null and Blanking Data Type**

Data Type	Description
0x10	Null
0x11	Blanking Data

### 13.5.3.3 User defined packet format

The User Defined Data Type values can be used to transmit arbitrary byte-based data, such as JPEG and 1226 MPEG4 data over the CSI-2 bus.

The packet data size in bits can be divisible by 8. For example, whole number of bytes can be transmitted.

For User Defined data:

- The frame is transmitted as a sequence of arbitrary sized packets.
- The packet size is vary from packet to packet.
- The packet spacing is vary between packets.

#### 13.5.3.3.1 ISP / CAM I/F for user defined packet

For supporting user defined packet, MIPI CSIS puts out more signals: 2 bits of byte validation.

Byte validation signal indicates what is valid byte in data of word size. In the following figure, n is 0, 1, 2, or 3.

Figure 13-61. Output Protocol of CSIS V3.3 in User Defined Format

The following table describes BVALID in detail.

**Table 13-28. Description Table of BVALID[1:0]**

BVALID[1:0]	Description
2'b00	All bytes in data bus are valid.
2'b01	Only byte 0 is valid.
2'b10	2 bytes from LSB are valid.
2'b11	3 bytes from LSB are valid.

### 13.5.3.3.2 Pixel clock of ISP wrapper for user defined packet

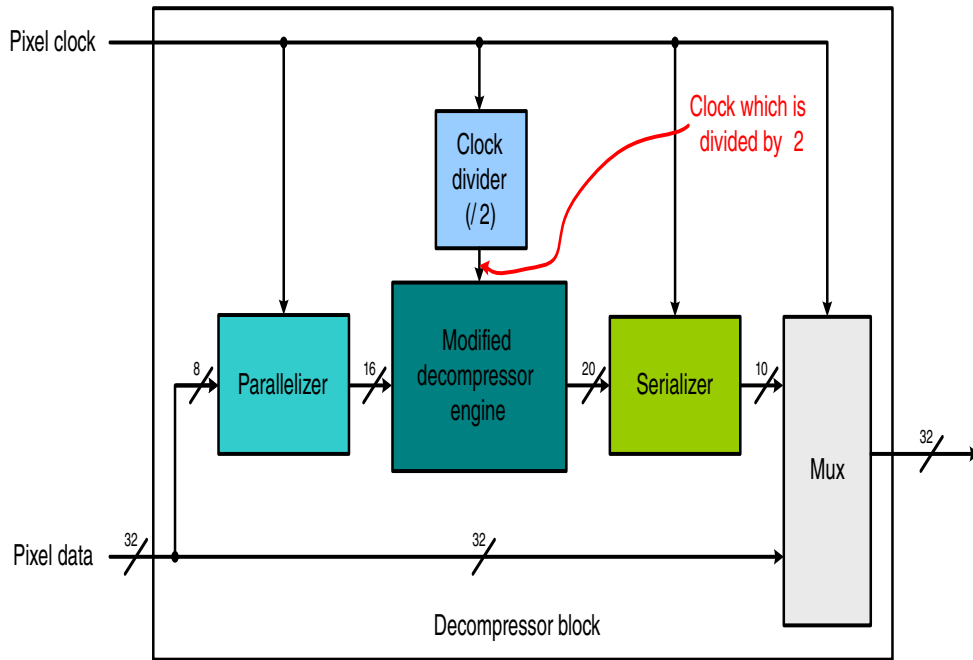

Since CSIS V3.3, Byteclk is not used for Pixel clock even in the user defined format.

### 13.5.3.4 Decompressor for Bayer RGB

In Annex E of MIPI CSI-2 standard spec, compress formula is described. CSIS V3.3 can support 6 / 7 / 8-to-10 formats and 10-to-14 formats.

There are two types of determining predictor to decompress which are Simple and Advanced method (Refer 5.2 and 5.8's decomp\_predict field). The Simple method is intended to minimize processing power and it is typically used with 8-10, 7-10 schemes. The Advanced method is more complex and provide slightly better quality, so it is usually used with 6-10 and 10-14 schemes. CSIS V3.3 can support both method at 6 / 7-10, 10-14 schemes, and only simple method at 8-10 scheme.

The following figure describes the block diagram of Decompressor logic in CSIS V3.3.

**Figure 13-62. Block Diagram of Decompressor**

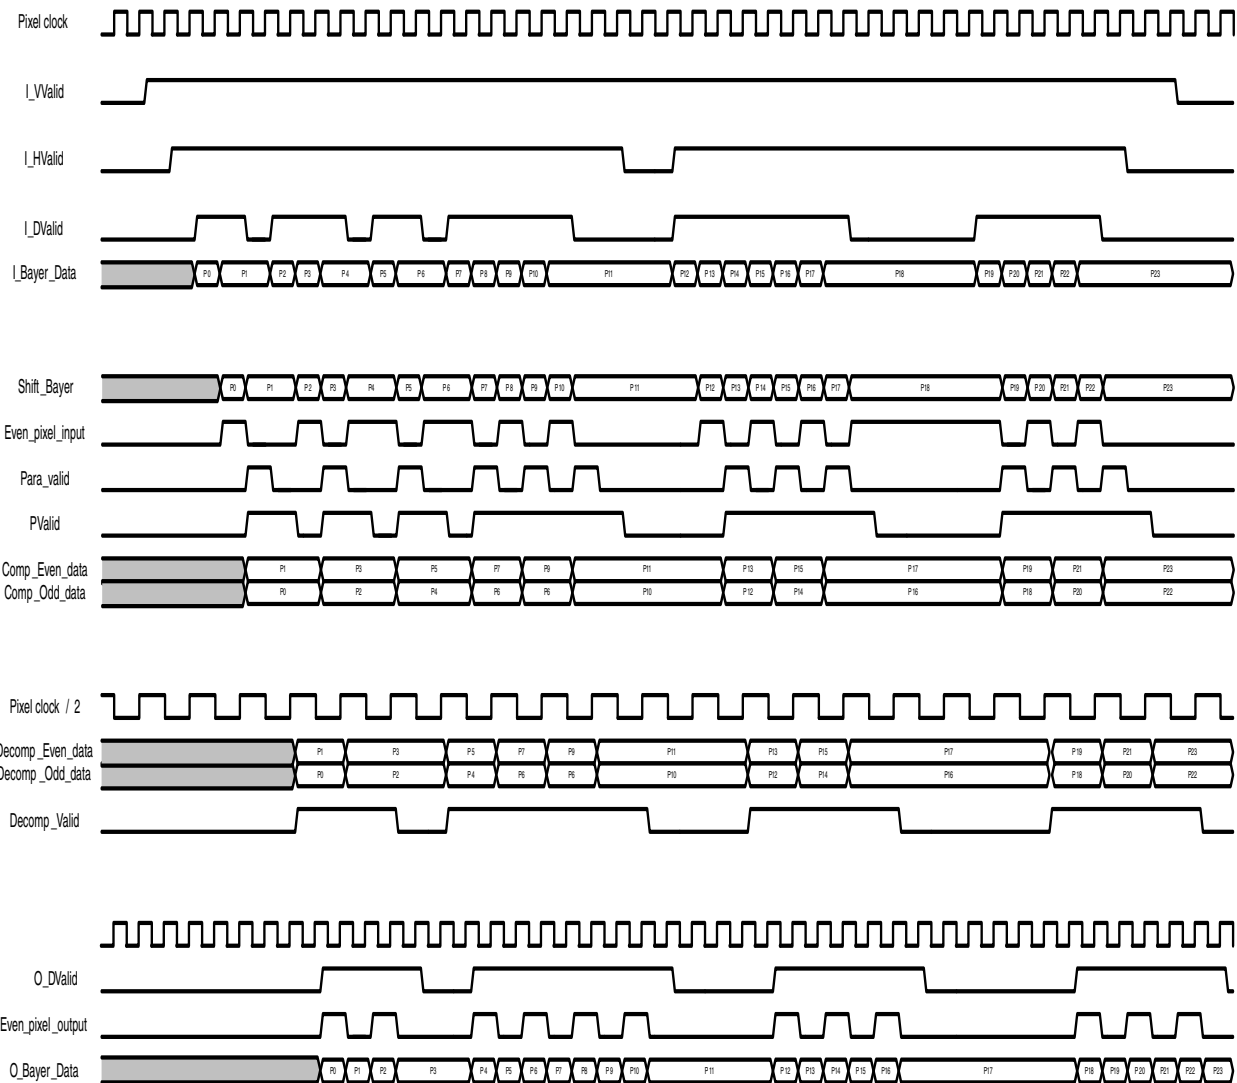

Decompressor engine was made by SysLSI Image team. It was modified for using Dvalid. Another logic of Decompressor was designed for processing two pixel per clock because of decompressor engine.

When camera module can send compressed Bayer RGB, user can be set CSIS\_CTRL and CSIS\_CONFIG registers. Turn the Decompress enable and format in CSIS\_CTRL register on. And then set the compressed format (RAW6, 7, 8) before turning camera module on.

The following table is an example of wave of decompressor.

**Figure 13-63. Waveform of Decompressor**

1<sup>st</sup> group [Figure 13-62](#) of is input signals of Decompressor. 2<sup>nd</sup> group of [Figure 13-63](#) is signals of parallelizer of Decompressor. 3<sup>rd</sup> group of [Figure 13-63](#) is output of Decompressor engine. The other group is output of Decompressor.

### 13.5.3.5 Interrupt

CSIS V3.3 has many interrupts for checking status, indicating error case and receiving generic data.

#### 13.5.3.5.1 Odd\_Before / Odd\_After / Even\_Before / Even\_After

These interrupts are related with generic and embedded data.

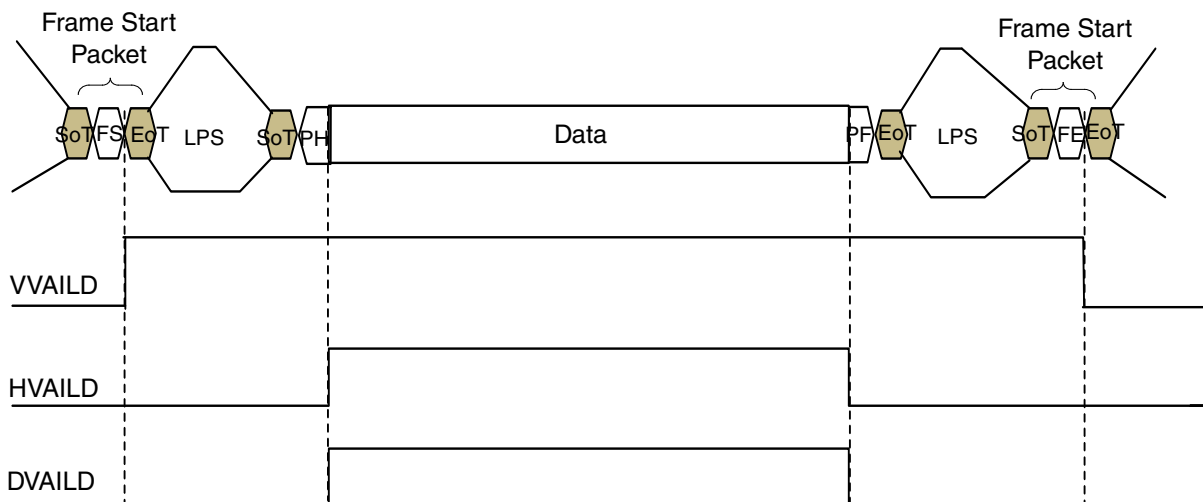

Odd\_Before and Odd\_After interrupts are generated in odd frame. Even\_Before and Even\_After interrupts are generated in even frame. Odd\_Before and Even\_Before interrupts are generated when Generic Short packet or Embedded 8-bit based packet is received before image data (Vertical Back porch area).

### 13.5.3.6 Synchronization short packet data type

Image Frame begins with a Frame Start and finishes with a Frame End packet. With these Frame synch packet, CSIS V3.3 generate Vertical Sync signal (VVALID). The Line synchronization packet (Line Start and Line End) generate Horizontal Sync signal (HVALID). But it can be generated by image data packet so that CSIS V3.3 does not support the Line Synchronization packets (0x02 ~ 0x03) and ignore it if it is received.

**Table 13-29. Synchronization Short Packet Data Type**

Data Type	Description
0x00	Frame Start Code
0x01	Frame End Code
0x02	Line Start Code (Not support)
0x03	Line End Code (Not support)
0x04 to 0x07	Reserved

**Figure 13-64. Synchronization Example**

### 13.5.3.7 Clock gating for Pixel clock in the idle state

Since CSIS V3.3, it gates the Pixel clock when the target Channel is in idle state. In the following figure, the CLK\_GATE signal is triggered at negative edge of pixel clock. The CLOCK\_OPEN signal is from VVALID in the Packet Controller. So, Gated pixel clock is alive during the whole frame. The CLOCK\_CLOSE signal is set when the O\_VVALID of ISP wrapper set to zero, then GATE\_FSM generate trail clock for flushing of the F/F in the ISP or CAM. After generating all the trail clocks, the GATE\_PIXEL\_CLOCK is closed. If the CLOCK\_OPEN is set during the TRAIL\_CLK state then it quit the state and enters the open state immediately.

Figure 13-65. Pixel Clock Gating Timing

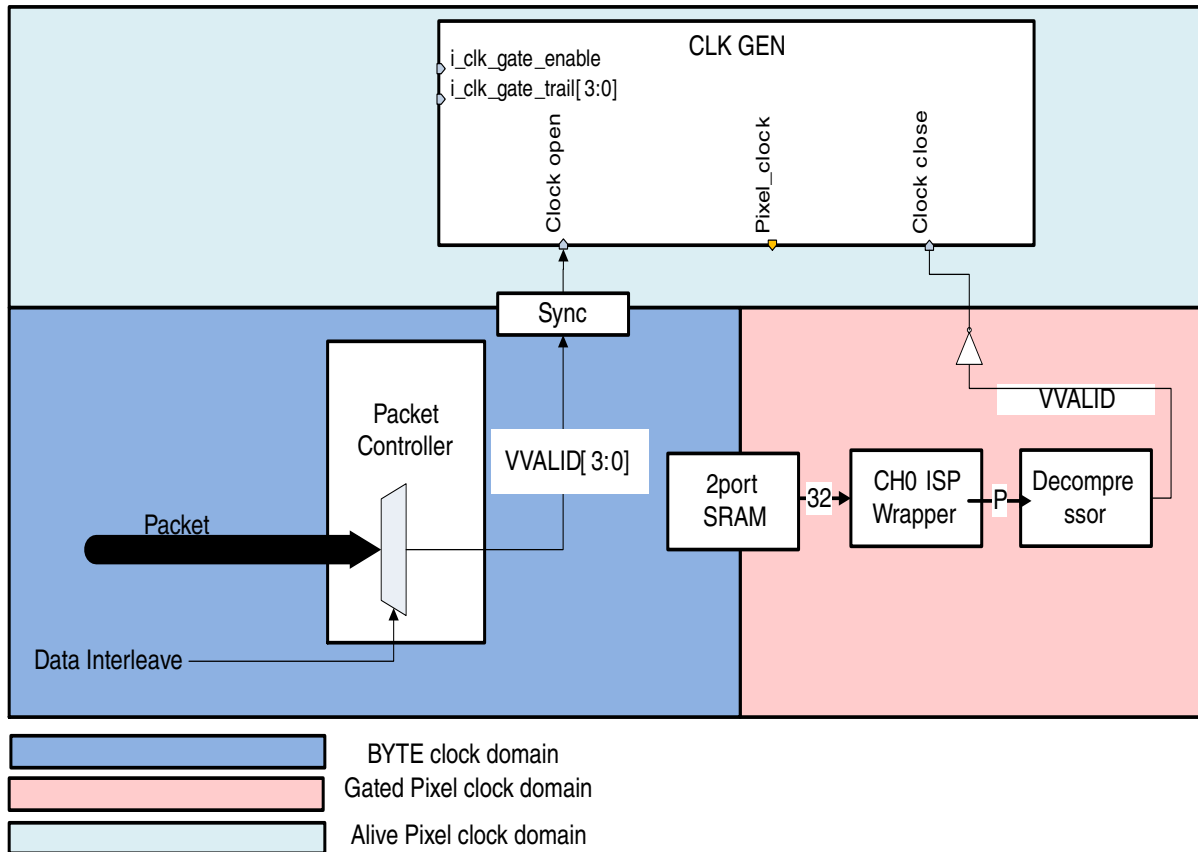

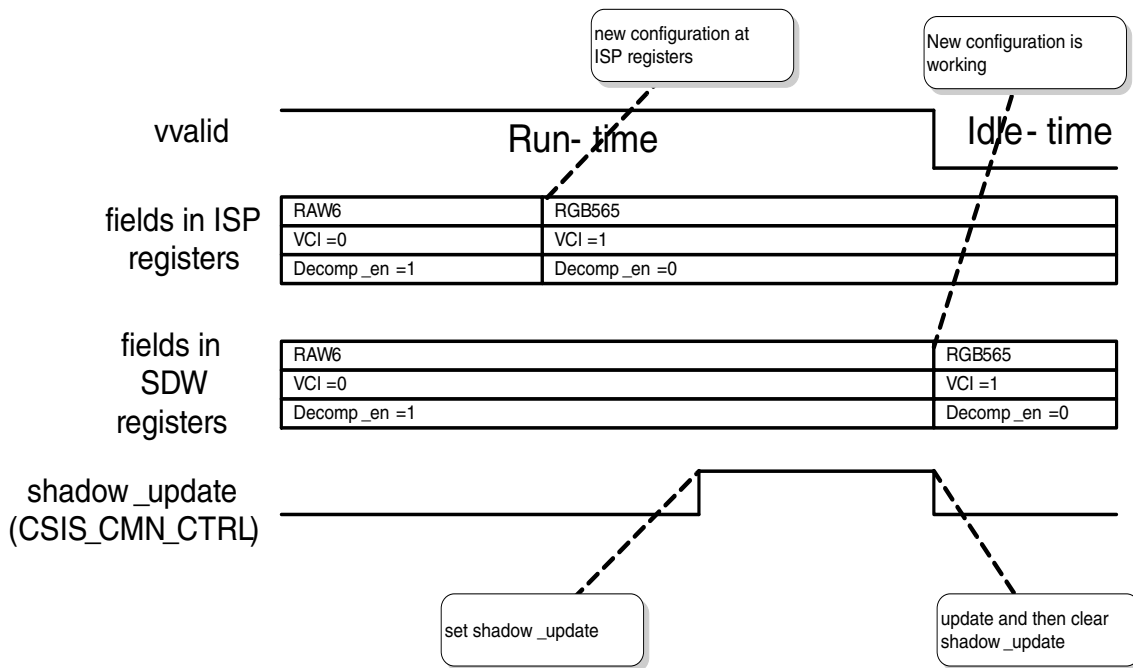

Figure 13-66. Clock Gating Block

### 13.5.3.8 Shadow update

The configurations related to ISP registers (which are dataformat, vci, resolution and so on.) cannot be varied during the run-time. So they are updated by programming 'UPDATE\_SHADOW' (in CSIS\_CMN\_CTRL register) in idle state. The scheme describes in the following figure.

**Figure 13-67. Operation of SHADOW\_UPDATE**

If the frame interleaving scheme (`interleave_mode` in `CSIS_CMN_CTRL` = 2 or 3) is used then the instance of entering `IDLE_STATE` at each ISP channels may be different. In this case, updating shadow registers can be delayed until that all ISP channels are in idle state by setting `UPDATE_SHADOW_CTRL`.

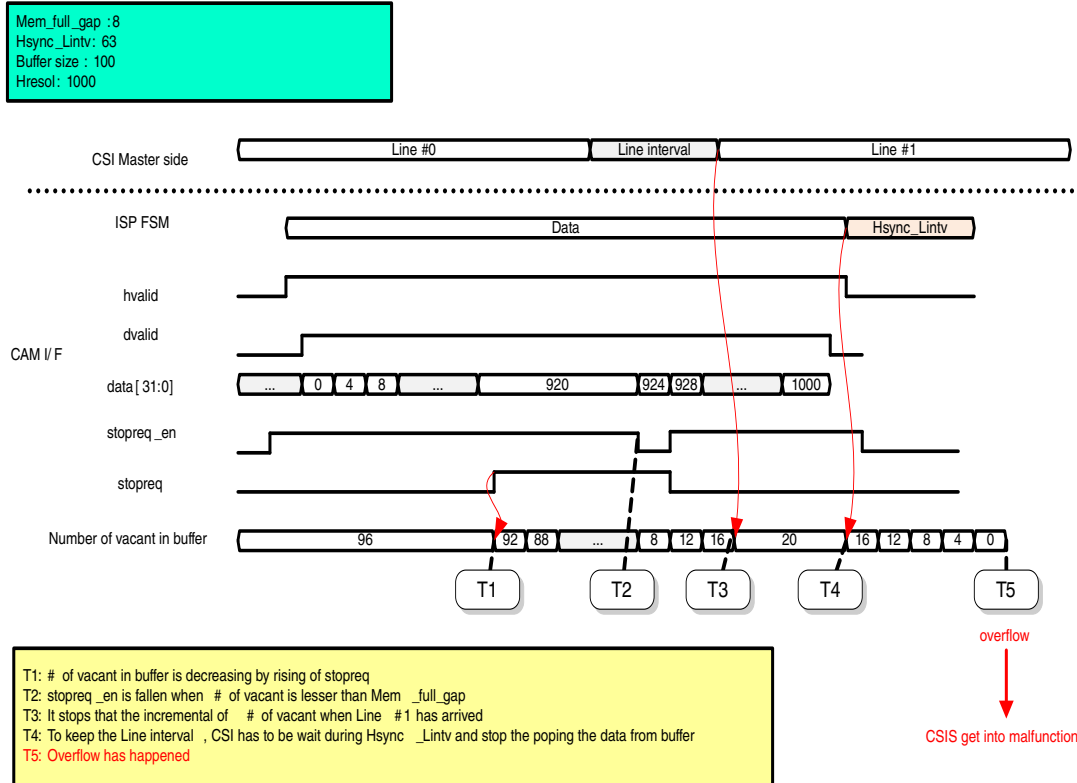

Figure 13-68. Operation of SHADOW\_UPDATE\_CTRL

### 13.5.3.9 Guide of MEM\_FULL\_GAP

**Figure 13-69. Relation Between MEM\_FULL\_GAP and Sync Interval**

Related with [Handshaking with back pressure](#), MEM\_FULL\_GAP in ISP configuration register should be set carefully because CSIS will be in malfunction if overflow has happened. MEM\_FULL\_GAP plays a role of preventing buffer overflow by popping out data from the buffer when the empty room of the buffer is lesser than the number of MEM\_FULL\_GAP. In the HSYNC\_LINTV state, it is stopped to pop out data from the buffer. So, the minimum value of the MEM\_FULL\_GAP should be greater than the amount of data stored during the HSYNC\_LINTV state. The related formula is following:

$$\text{MEM\_FULL\_GAP} \geq (\text{HSYNC\_LINTV} + 1) * \text{Pixel clock period} / \text{Byte clock period} + 8$$

#### NOTE

Propagation delay factor

For example:

Condition: HSYNC\_LINTV = 31, Pixel clock = 666 MHz, Byte clock = 250 MHz  
 MEM\_FULL\_GAP:  $(31 + 1) * (1 / 666) / (1 / 250) = 12$

‘Don’t stop last line’ plays a role of preventing abnormal operation by ignoring stop request when the last line is transferred. So, do not change the ‘Do not stop last line’ values (default = 4'b1111) except for debugging.

### 13.5.3.10 Clock Specification

MIPI CSI may have three clock sources: RX\_BYTE\_CLK\_HS0, I\_PCLK, and I\_WRAP\_CLK.

I_PCLK	PCLK is system clock generated by general processor PLL.
RX_BYTE_CLK_HS0	This signal comes from data lane 0 of D-phy.
I_WRAP_CLK	I_WRAP_CLK is external clock for pixel clock what is for using ISP or CAM I/F.
I_DTLPCLK	D-phy Scan Test clock which is needed at 45 nm process (since 32 nm D-PHY has its own Test clock).

#### 13.5.3.10.1 Clock domain

Figure 13-70. Block Diagram of Clock Domain

Three number of clock domain of CSIS V3.3 is:

- BYTE clock (RX\_BYTE\_CLK\_HS0)
- External clock (I\_WRAP\_CLK)
- APB clock (I\_PCLK)

Pixel clock uses one of those clocks (Wrapper, APB), since CSIS V3.3 does not use BYTE clock for Pixel clock in the User defined data type.

The relationship between input and output bandwidth is that the output bandwidth should be faster than input bandwidth. There is an equation of previous relationship.

$(\text{freq. of RX\_BYTE\_CLK\_HS}) * (\text{number of data lane}) * 8 \text{ bits} \leq (\text{freq. of Pixel clock}) * (\text{bitwidth of image format})$

### 13.5.3.11 Interface Signals

#### 13.5.3.11.1 Reset and clock signal

Table 13-30. Variation of Clock and Reset

Clock and Reset	Frequency	Clock Generator	Usage
I_PRESETn	—	—	Global Asynchronous reset
I_PCLK	—	System controller	Main control clock (system dependent)
RX_BYTE_CLK_HS0	up to 187.5 MHz (1.5 G) 125 MHz (1 G)	Data lane 0 of D-phy	MIPI CSI processes data with ByteCLK
I_WRAP_CLK	up to 200 MHz	External clock source	Output pixel clock
I_DTLPCLK	up to 200 MHz	External test device	For D-phy scan test mode

#### 13.5.3.11.2 PPI (PHY-Protocol Interface) signals

BandCtrl and HSzeroCtl signals of following table are additional signals for D-phy timing configuration. The other PPI signals in the following table are compatible with MIPI D-phy spec.

Table 13-31. Protocol-to-Phy Interface Signal List

Signal	I/O	Description
<b>Clock lane</b>		
STOP_STATE_CLK	I	Stop state indicator (active high)
ULPS_CLK	I	ULPS state indicator (active low)
ENABLE_CLK	O	Clock lane enabler
<b>Data lane (lane0 ~ 1 common, % = 0 and 1)</b>
